APPENDIX E

MATLAB DIODE MODELING (C_j EXPONENTIAL FIT)

This appendix presents a Matlab program used for diode modeling to fit an exponential equation to data points for C_j. The function Cjerror.m is called from Fit_Cj_Exp.m to calculate the sum of squares error for a given set of parameters.

```
% Fit_Cj_Exp.m
% Jonathan Hansen
% fit an exponential curve for Cj vs Vj to data points
%
% Cr(v) = Co * sqrt(Vo/(Vo-v))                              , v < alpha*Vo
% Cf(v) = Cr(alpha*Vo) + Cr'(alpha*Vo) * (v-alpha*Vo)   , v > alpha*Vo
%
% adjust Co, alpha, & Vo for least squares error between equation & data

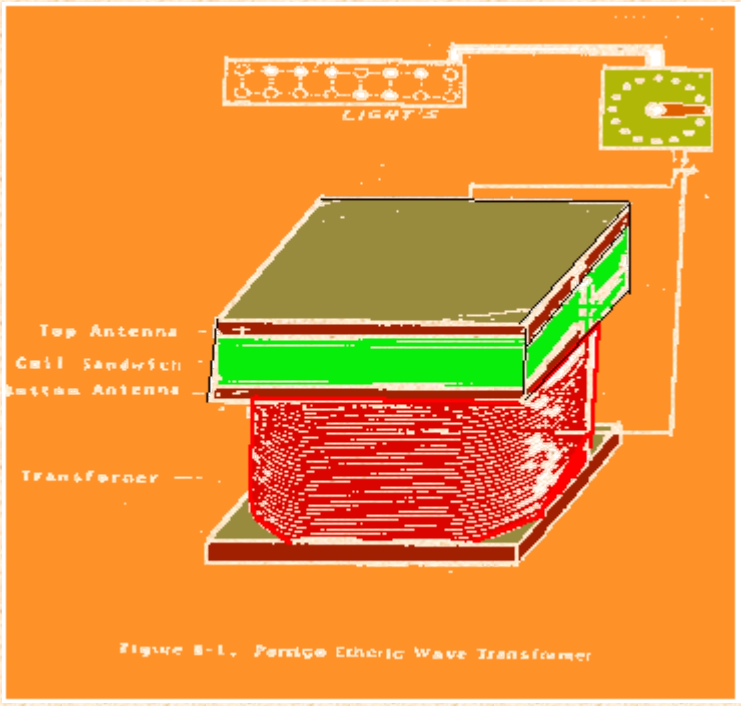

Figure 8-1. Perrigo Etheric Wave Transformer

METHOD AND APPARRATUS FOR ACCUMULATING ELECTRIC ENERGY AND TRANSFORMING ETHER ELECTRIC ENERGY

Drawings by Geoff Egel ,Content Author unknown

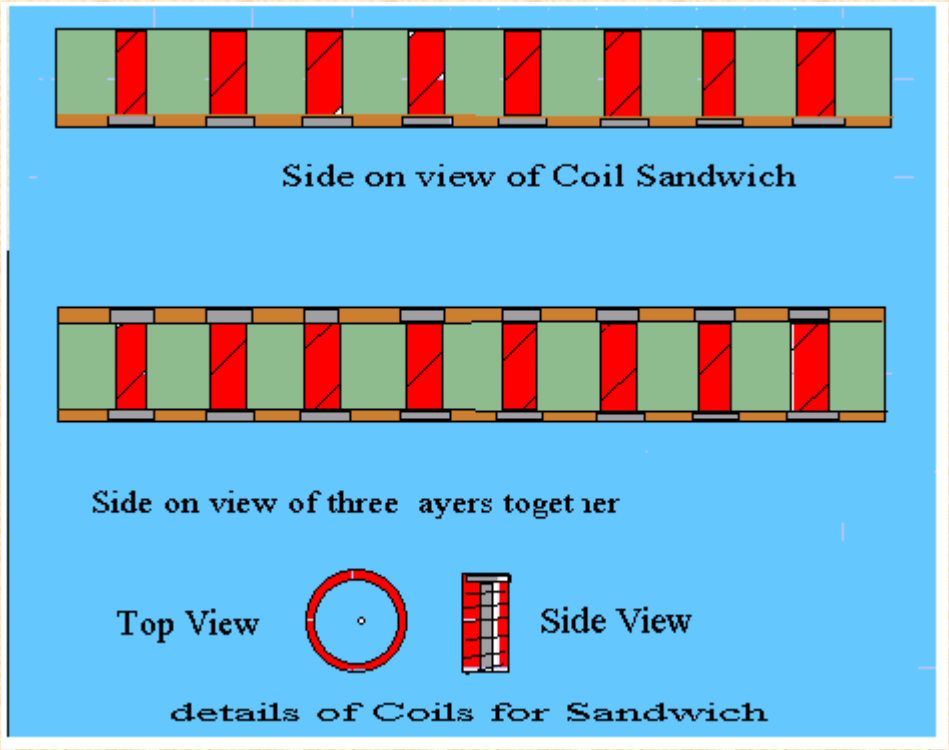
In 1926. Harry E. Perrico claimed to have discovered a method to tap the energy from atmospherics. He even had a car which he converted to run on electricity. that was generated in his ether wave accumulator".

He applied for a patent December 31 1925 with serial number 78,715 being assigned. Perrigo's patent application Is considered a "classic" In patent law and Is listed under the classification of Perpetual Motion Machines and other Impossible Inventions.

Despite the Patent Office's attitude towards Perrico's invention, there were a number of reputable people who claimed to have witnessed his device In action producing useable electric power.

The existence of electromagnetic radiation, the modem term, or electric waves In the ether as it used to be called was known by Hertz, a research scientist who discovered the photoelectric effect

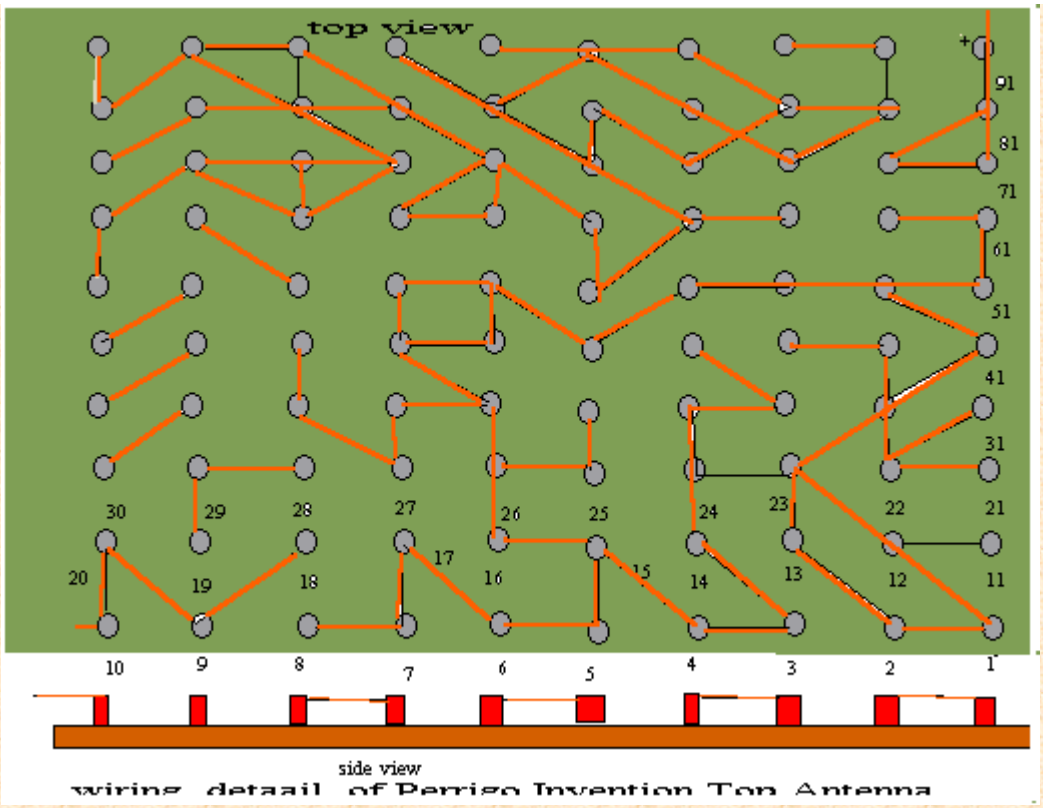
In 1887. Atmosphierics, an electrical disturbance in the atmosphere, were known to produce noises In the early radio telegraph stations, some being strong enough to drown out the received signal.



> Perrigo deduced that here was a possible source of electrical power.

All that was needed was a method of transforming the existing radiation Into useable energy. Hie claimed to have developed a mechanism to intercept and collect from the general ether field electric wave energy and to transform it into useable electromotive force.

The basic method he used was an antenna arrangement which collected and resisted the Incoming energy raising It to a high enough current level where it could be run through a special electrical transformer to further intensify the available power.

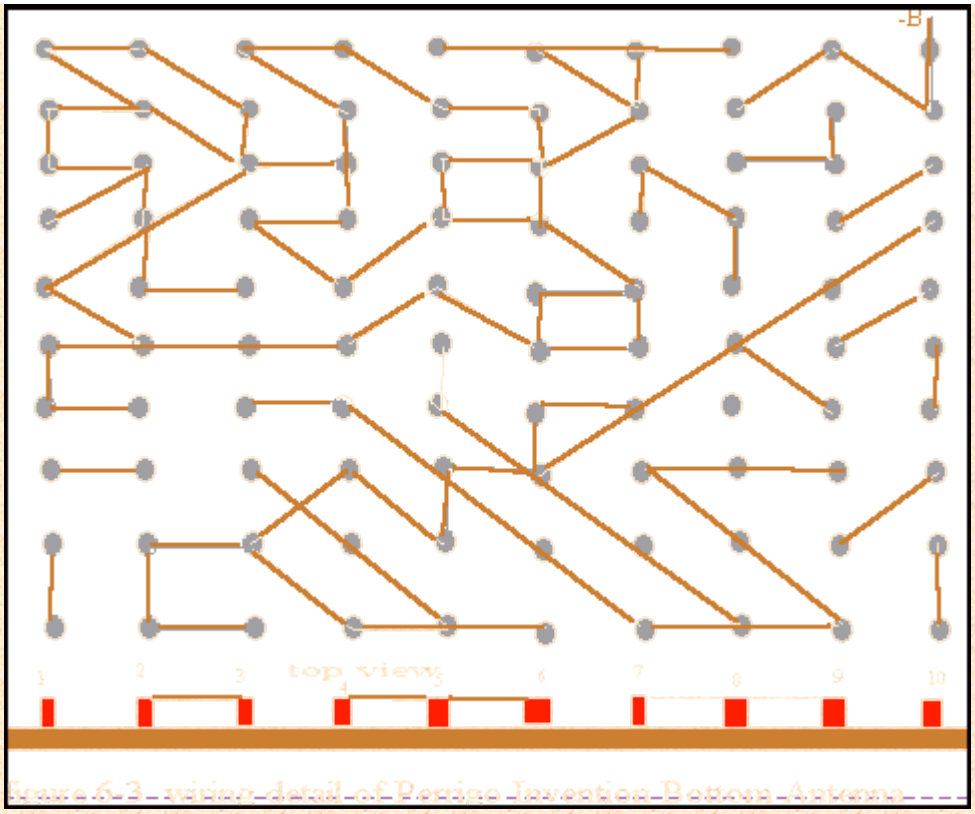


wiring detaail of Perrigo Invention Top Antenna

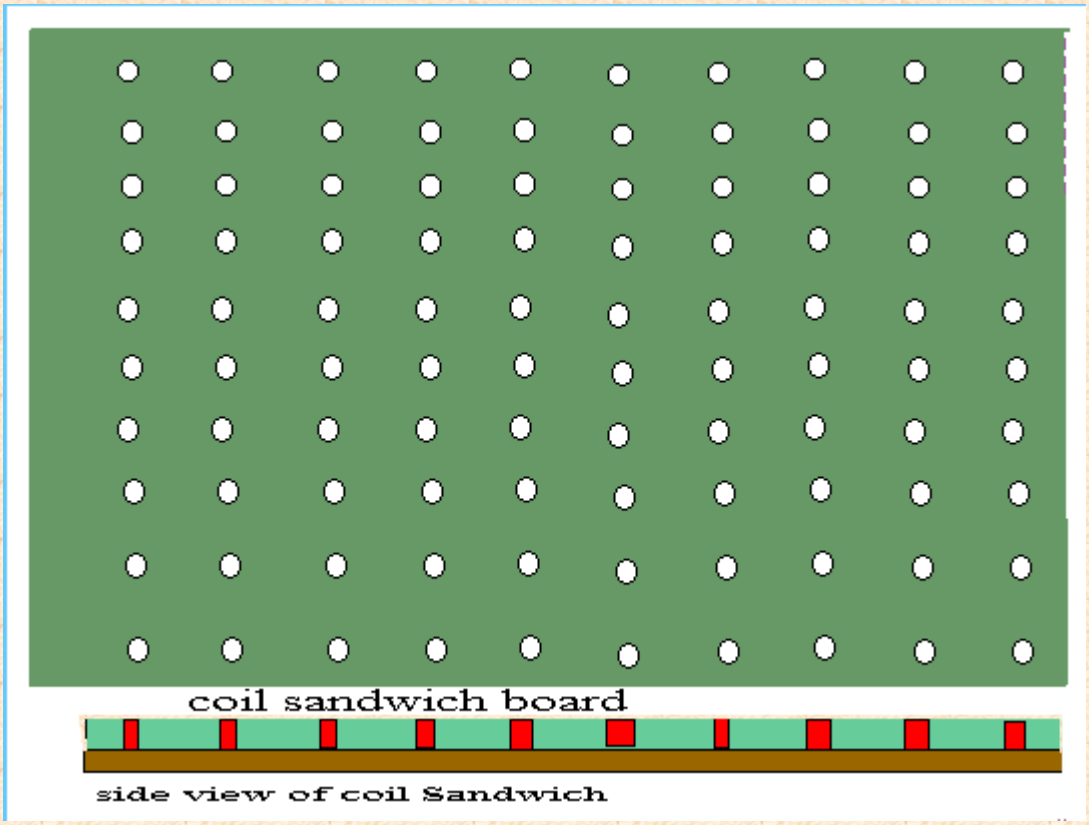
Perrigo's antenna was derived from his experiments with various wire shapes, sizes and arrangements. One of his more successful attempts was to partially pound 100 roofing nails into a board a 10 x 10 array and wrap very fine wire around each nail,making it a small electromagnet.

Then by trial and error approach he connected the ends of the electromagnets to other nails in such a way that there was a maximum voltage between the wire and the nail.. His patent application mirrored this electrical connection scheme in a more refined electromechanical approach.

Two accumulator plates were made with 100 round protruding knobs in a square 10 X 10 array



The accumulator plates were then sandwiched together with an insulator material between them. The insulator had 100 holes matching the protrusions on the plates. Placed in each hole was a special coil wrapped around a bundle of wire . Once the accumulator plates were sandwiched ,a measureable electrical voltage existed between points A and B on plates one and two respectively.



A very complicated transformer was attached to these two points.

The plates were set on top of the transformer and Perrigo claimed this arrangement enhanced the energy accumulation process.

I have no idea of what materials the plate or protrusions were made The patent drawing would lead one to believe they are the same material.

It could be a metal or a nonconductor. such as wood or a combimation. The protrusions were connected by the same wiring scheme

Previously mentioned for the roofing nail model. The connections were different for the two plates.

(See diagrams for the plates connections

Abstract

Escola Técnica Superior d'Enginyeria de Telecomunicació de Barcelona
Departament de Teoria del Senyal i Comunicacions

degree of Engineer

by César Meneses Ghiglino

This work focuses on designing, fabricating, measuring and testing each component of a Rectenna. A rectenna consists of an antenna and a rectifier circuit that is optimized for incoming signals of low power density. This rectenna is used to harvest electric energy from the RF signals that have been radiated at:

- GSM-850
- GSM-900 (downlink: *935-960MHz*)
- GSM-1800 (downlink: *1805-1880MHz*)
- ISM band centered in 2.45 GHz.

This work contains antenna design techniques using Ansoft HFSS software and methods to simulate rectennas using Harmonic Balance and electromagnetic full-wave Momentum with the Agilent Advanced Design Software (ADS2008).
For the antenna fabrication it was used a LPKF Milling machine. And for measurements a Vector Network Analyzer (VNA), spectral analyzer, analog signal generator, multimeter, and anechoic chamber were used.

Agradecimientos

En las siguientes líneas, quiero agradecer a aquellas personas, a las que considero más importantes en esta etapa, sin el apoyo emocional, material, etc. por su parte, este trabajo hubiera sido más duro.

Primero agradecer a mis padres y mis hermanos, por su apoyo y total confianza, por ser una motivación y ejemplo para mí, por animarme a hacer cosas de las cuales se puedan sentir orgullosos, a Yvett que siempre ha sido la primera persona en animarme y apoyarme en todo, tanto en Perú, como cuando empezó esta etapa de mi vida en España. A mis tíos, Eric y Diana, con su apoyo hicieron que yo me sintiera en familia siempre, a mis primas, Indira y Zoraida, por ser el toque infantil, necesario, que no había experimentado hasta ahora y que alegró muchas tardes. A todos mis compañeros de la UPC, principalmente a aquellos que como yo, vinieron desde lejos y comprenden el sacrificio de una tesis, más aun cuando la familia y las personas más cercanas a tu vida están lejos.

A todas las personas del CTTC: a Apostolos y Ana, por ser los principales artífices de esta tesis, por su paciencia, comprensividad, y por propiciar un excelente ambiente de trabajo, a Selva, por su infinita colaboración, paciencia y ayuda en los momentos importantes del proyecto.

A todos los amigos que he conocido en el transcurso de estos dos años en Barcelona, ¡son parte de esta excelente etapa!

¡Muchas Gracias!

Chapter 1

Introduction

Wireless multimedia systems are receiving increasing research and application interests. But improvements are still required to provide higher data-rate links, for instance, the transmission of video signals. Therefore, ultra-wideband (UWB) communication systems are currently under investigation and the design of a compact wideband antenna is very essential. To overcome the inherently narrow bandwidth of microstrip antennas, various techniques have been developed to cover the entire UWB bandwidth, such as L-/F-shaped probe to feed the patch, triangular patch, U-/V-slot monopoles, among others.

And, why don't we use the same antenna to collect the energy that is being radiated at several frequencies? Clearly it is much more effective to harvest the energy of several services at the same time than collecting only one service energy; this is why the idea of an UWB antenna for harvesting energy is entirely feasible.

The meaning of Energy Harvesting (also called energy scavenging or power harvesting), is the process by which energy from different sources is captured and stored. Generally, this definition applies when we talk about autonomous devices that require a low amount of energy to function.

Currently, energy harvesters do not provide sufficient amount of power to produce mechanical movements or temperature changes (cooks, refrigerators, etc) because there

aren't technologies that capture energy with great efficiency. But these technologies do provide the amount of energy needed for low-power devices that can operate autonomously.

Another advantage of this type of technology is that, unlike the production of large-scale power, we can consider that the energy source is free if you take into account the electromagnetic energy of transmitting mobile stations and radio and TV broadcasting antennas.

The use of batteries has two disadvantages: the lifetime of the batteries is very limited even for low-power batteries, requiring impractical periodical battery replacement, the use of commercial batteries usually overkills the power requirements for uW sensor nodes, adding size and weight while creating the problem of environmental pollution due to the deposition of these batteries, as well as increases significantly the cost overhead of disposable nodes.

This work focuses on incident low-power density; designing, measuring and testing a Rectenna to harvest electric energy from the RF signals that have been radiated by public communications systems (GSM-900 and GSM-1800) and the 2.4 GHz ISM band; also the work is motivated by two types of applications: powering low-power sensor networks and RF energy recycling

1.1 Overview

In this thesis, the work involves the design, simulation, fabrication and measurement of each of the components of a rectenna (rectifying antenna circuit) has been divided into the following chapters.

- Chapter 1 is this overview.
- Chapter 2 reviews some of the history of microwave power transmission from its beginnings with the empirical work of Hertz, to Tesla's experiments and describing the evolution of power transmission in free space. Subsequently, it describes how the approaches of some projects, together with studies funded by various companies, encourage the evolution of technologies in the field of microwave power transmission. After the history, an overview of some low power sources for energy harvesting is shown, then we emphasize in the RF-EM energy harvesting and a feasibility study for our application is shown.
- Chapter 3 first describes the main parameters of an antenna for its design. A brief background about UWB antennas and microstrip antennas is introduced. The introduction of the design software (Ansoft HFSS 11) and a brief description of the

simulation method used for the antennas will be shown as well. Then a description of the design procedure and simulations of our base-antenna, which bandwidth range from 850 MHz to 6 GHz is explained. Thereafter, the miniaturization techniques that we applied to the base-antenna and the subsequent building procedures of the “size-improved" antenna will be shown. Finally, some pictures and measures will be explained.

- Chapter 4 describes everything about the rectifier circuit. It begins by describing the operation of a half-wave rectifier and an introduction to the Schottky diode is made, then a brief review of the efficiency of power conversion from RF to DC is shown. For rectifier circuit simulations, the software used was the Agilent ADS2008; this chapter also explains each of the tools used to perform these simulations. For a good overall efficiency, several rectifier circuits were tested, in this chapter, the simulations of each of them and their schemes are detailed. In order to avoid the soldering of a high number of components that may affect the overall efficiency, a transformation from LC components to Microstrip Lines, and their simulations, will be explained. Finally the results of the measurements are shown.
- Chapter 5 shows some possible future applications of rectennas as well as some new substrates materials for antennas that are currently being studied and tested. Finally the conclusions are shown.

Chapter 2

State of the Art

2.1 History of Power Transmission by Radio Waves.

When we talk about power transmission by radio waves, we mean a complex process that can be divided into three stages: 1) to transform the DC power in RF power, 2) RF transmit this RF power through a wireless medium from one point to another; and 3) turn back the received RF power to DC power. Then, we can conclude that the overall system efficiency is directly dependent on the efficiency of each of these stages. The modern history of power transmission studies, in many respects, has focused on improving and developing the elements of the transmitting and receiving ends of this system, focusing on high efficiency, low costs, reliability and low mass.

2.1.1 The Early History

Power transmission dates back to the early work of Hertz [1], He wasn't only the first who showed the propagation of electromagnetic waves in free space, he was also the first to experiment with parabolic reflectors at both the transmitter and receiver ends.

At the end of the 19th century, Nikola Tesla, a genius in the area of generation and power transmission became interested in their studies applied to power transmission from one place to another without wires. His first attempt was carried out in 1899 in Colorado, USA,

with the support of the Colorado Springs Electricity Company. He built a giant coil over which rose a mast of 70 meters with a copper sphere at the end. However, there is no record of how many energy was radiated to the space and whether there was any collected energy at any other place. From today's perspective, we can say that Tesla's attempts of efficient power transmission were ahead of the developed technology of this time. 30 years later, in 1934, H. V. Noble, this time in a laboratory, using two 100 MHz dipoles separated by 8 meters, collected several hundred of watts. With this experiment, he laid the basis for power transfer demonstrations.

The main cause of the lack of interest to develop this area was that several experts had determined that to achieve high efficiencies, concentrations of electromagnetic energy in a narrow band were needed. During the first 35 years of the 20th century, there were no devices that have these capabilities, but in the late 30's, the development of the velocity-modulated beam tube (Klystron tube) and the microwave cavity magnetron, allowed the generation of microwave power dedicated to this new technology.

2.1.2 The Modern History of Free-Space Power Transmission.

The modern history of power transmission, as far as microwaves are concerned, not only includes the development of technologies for microwave power transmission (MPT), the approach also includes various applications, whose achievements contributed to the development of new ideas and new technologies. This history of free-space power transmission will be divided in the early period beginning in 1958 and the period beginning in 1977 with the assessment study, by the DOE / NASA, of the concept of the solar-power satellite.

2.1.2.1 The Early Beginning

In the late 50's, several developments, made the idea of transmitting large amounts of power with high efficiency a reasonable concept, among these developments was the growing need to be able to communicate over long distances with line of sight. This could be solved with some kind of platform located at high altitude. Subsequently, this was solved with a satellite, but back then, a microwave powered vehicle was a logical approach.

Raytheon Company proposed a platform supported by a large helicopter, but did not get the necessary support of the Defense Department; however, they encouraged the development of technologies necessary to make it feasible. Among the technologies that were needed to develop were the high-power microwave tubes required for the transmitter and the technology to directly convert microwave-dc power to drive the motors of helicopter rotors. Between the years 1960-63 were developed some solutions to these problems (the Amplitron and thermionic rectifier respectively) and they did some demonstrations to

receive funds, but some flaws (as the high directivity of the receiving antennas attached to the helicopter and the short-life of thermionic diode) made that the project couldn't be successfully finalized. Due to the low collection efficiency of energy and the directivity of the horns, the concept of rectenna was conceived. This solution consisted in to attach the rectifiers in half-wave dipoles and put a reflector panel behind them. With the application of this rectenna concept the helicopter project (Fig 2.1), the first of July 1964, the first flight of a heavier than air vehicle supported solely by power received from a microwave beam was made.

2.1.2.2 Sponsorship by Marshall Space Flight Center (MSFC)

In 1970, due to the emphasis on developing a free-space power transmission system for a set of physically separate satellites, the MSFC, contracted Raytheon for a system study to be carried out in 1970. In this experiment conducted in 1970, the overall system efficiency obtained was 26%; over the next four years, with the aim of improving the overall system efficiency some other developments were made like a better antenna design, the develop of better ways to launch the microwave beam, the develop for better tools to measure the overall efficiency and better analytical tools for a better understanding of the operation of the rectenna.

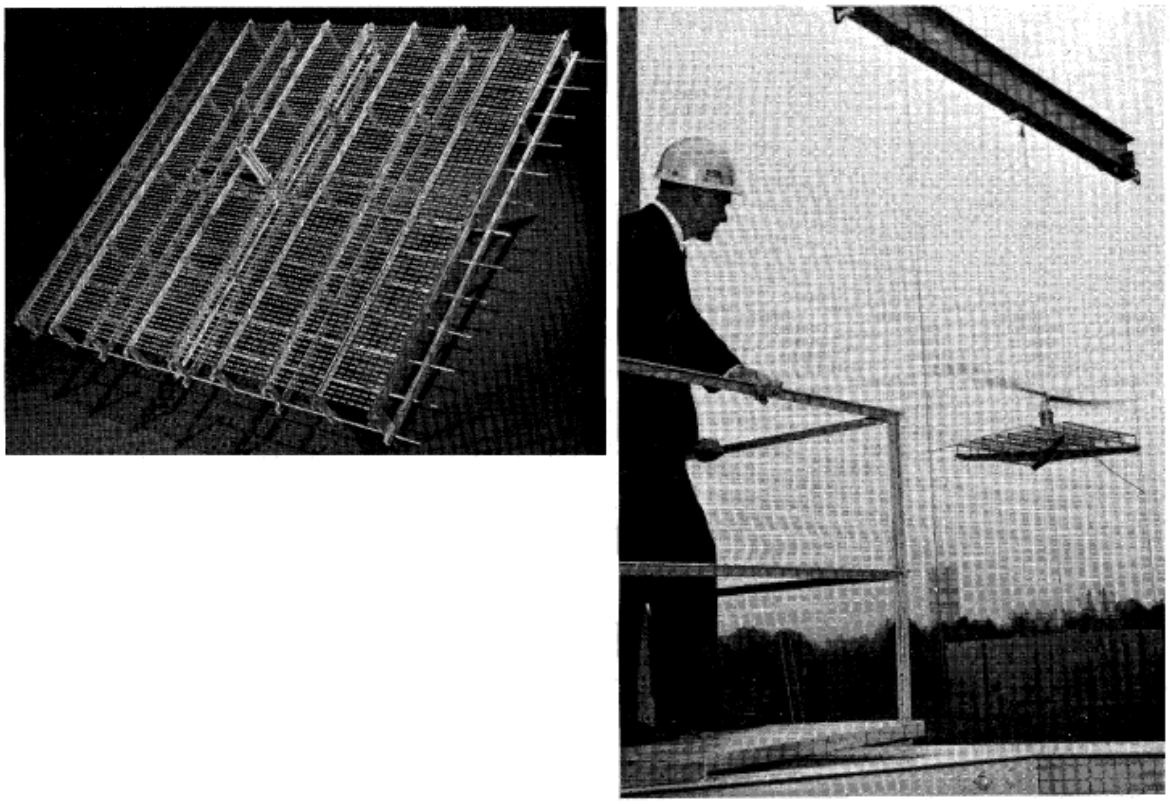

Fig 2.1.1 (left) shows the rectenna made to fly the first helicopter powered by microwaves and (right) the complete system in a test flight of 10 hours, held in October 1964

In 1971, the introduction of the gallium arsenide Schottky-barrier diode with an improved efficiency and greater power handling capacity that the diode that was previously used. This sponsorship program culminated with the construction of a laboratory power transmission system with all the technology that had been developed during the last years. In this experiment, the efficiency obtained was 48% +- 2%.

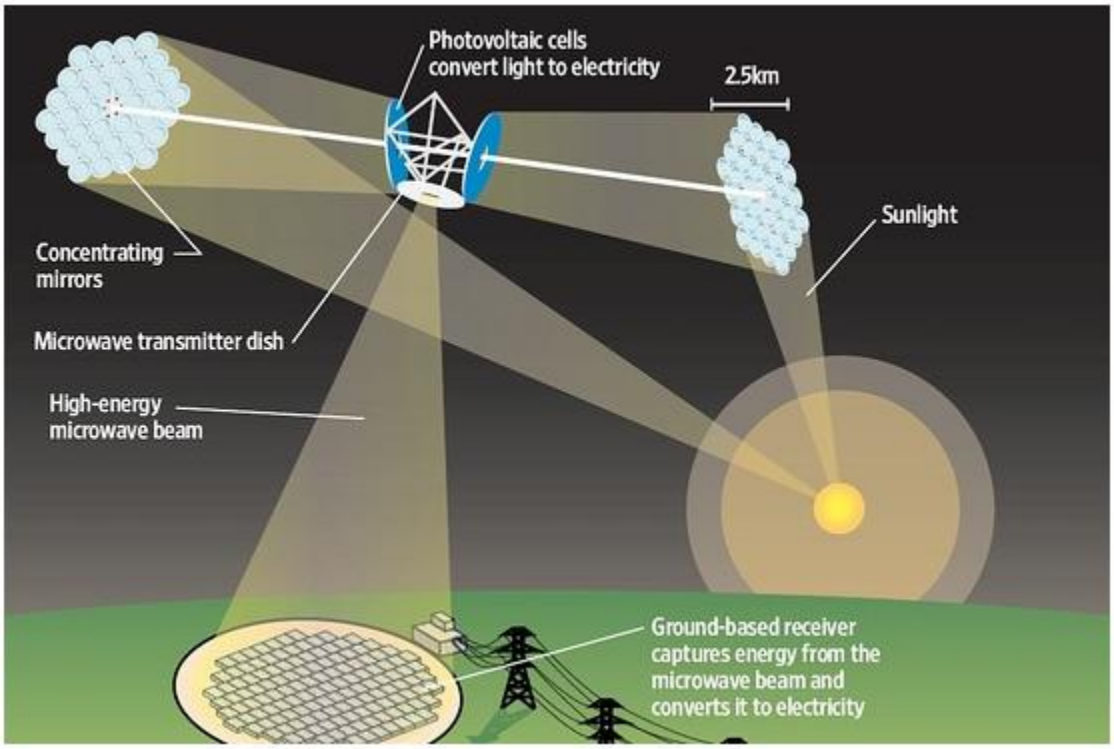

Fig. 2.1.2 Show the complete diagram of the SPS concept [2].

2.1.2.3 Progress Associated with Initial Interest in the Solar-Power Satellite (SPS) Concept

In 1968, Dr. Peter Glaser introduced the concept of SPS (Fig. 2.2). In this concept, the sun's energy is captured in orbit, converted into microwave power and then beamed to the Earth where subsequently it would be converted into electric power. This idea caught the attention of many companies interested in developing this project that seemed to be a possible solution for the growing demand for energy. A team of four companies (Arthur D. Little, Raytheon, Grumman Aerospace and Textron) was formed to develop a technical and economic feasibility study of the project. After six months of study, in 1971, the results of the technical investigation with favorable results encouraged them to send a letter to the director of NASA suggesting support for the SPS concept.

In 1973, the NASA's Office of Implementation, showed support for any additional development and also an special interest in the demonstration of the part of the system that

was responsible for power transmission. In 1975, the Goldstone demonstration was carried out, using a rectenna of 88 square meters, the power was transferred over a distance of 1 mile and a DC output of 30 kW was obtained; for the NASA and aerospace communities this demonstration was very important because it gave credibility to the power transmission and its use in the SPS concept. Concurrently, Raytheon developed a study sought to determine the critical technology areas of the SPS concept; this study concluded that these areas were: the DC to microwave conversion and the phased array antenna in the satellite. The development and improvement of these areas is considered the basis for many other technologies used in future applications.

A study supported by LERC in 1976-77, resulted in significant improvements in electrical and mechanical rectenna technology. The most important improvement was the mechanical change of format of rectenna, moving from a three-plane system, where bussing is done behind the reflector plane, making it more expensive, heavy and complex, to a system of two planes where there is only the reflector plane and a fore plane where all the microwave functions, rectification and DC bussing are held.

2.1.2.4 Later Period: Microwave Activity under DOE/NASA Concept Development and Evaluation Program for the SPS.

NASA, with the purpose of managing the energy that would be collected on Earth from the SPS system, involved ERDA (Energy Research and Development Agency) in the project. In 1977 ERDA began a three-year program called DOE/NASA Concept Development and Evaluation Program that resulted in a 670-page report summarizing the studies and findings. From these results, the most important for the development of microwave power transmission (MPT) was the suggestion of using the microwave oven magnetron. The program DOE/NASA SPS ended in 1980 with the conclusion that there was no reason for not continuing with the development and implementation of the project, but a program did not materialize. In retrospect, we can say that the greatest contribution of the SPS concept upon microwave power transmission (MPT) was the development of technologies that later replaced the classic super power tubes, for active phased array consisting of a large number of identical modules easy to manufacture using low-power microwave generators derived from the magnetron.

2.2 Low Power Energy Harvesting

Energy harvesting has been around in the form of windmills, watermills and passive solar power systems. In recent decades, technologies such as wind turbines, hydro-electric generators and solar panels have turned harvesting into a small but growing contributor to

the world's energy needs. This technology offers two significant advantages over battery-powered solutions: inexhaustible sources and little or no adverse environmental effects.

The most promising low power harvesting technologies extract energy from vibration, temperature differentials and light. Scavenging energy from RF emissions is interesting, but the energy availability is at least an order of magnitude less than the first three. Table 2.1 shows the estimated harvested power for different kinds of energy sources; we can observe that the estimated RF/EM harvested power along with the human vibration/motion harvested power, are the lowest values. Generally energy harvesting suffers from low, variable and unpredictable levels of available power.

The large reduction in power consumption achieved in electronics, along with the numbers of mobiles and other autonomous devices are continuously increasing the attractiveness of low power harvesting techniques. Consequently the amount of research in the field, and the number of publications has risen greatly.

Energy harvesting devices are particularly attractive as replacements for batteries in low-power wireless electronic devices. The cost of procuring, storing and getting someone to change a battery can easily cost as much as an energy harvester. A recent study [3] found that energy-harvesting systems are cost-comparable with systems using long-life batteries, over a ten-year lifetime.

2.3 EM/RF energy harvesting

When we refer to EM/RF harvesting, we do not refer to energy sources that have been specifically designed for powering wireless devices, we talk about the energy that we can collect from public services. In cities and very populated areas there is a large number of EM/RF sources like broadcasting radio and TV stations, mobile telephony base stations, and wireless networks. It is possible to collect part of this energy and convert it into useful energy. For our application, the main interest is in telecommunication services operating in the microwave region of the frequency spectrum, especially Global System for Mobile Communications (GSM) and Wireless Local Area Network (WLAN). As the most commonly used frequencies are well known, low-power devices have an antenna and a rectifier circuit (Rectenna), optimized to maximize energy harvesting at these frequencies[4]. For these services and their frequency bands, we can design printed antennas with dimension in the order of a few cm^2.

In laboratory environments, efficiencies above 90% have been observed, but when harvesting energy in the GSM or WLAN band on real scenarios, one has to deal with very low power density levels [5].

Table 2.1: Energy Harvesting Estimates [6] [7]

Energy Source Harvested Power	Harvested Power
Vibration/Motion	
Human	4 μW/cm^2
Industry	100 μW/ m^2
Temperature Difference	
Industry	1 – 10 mW/ cm^2
Light	
Indoor	10 μW/ cm^2
Outdoor	10 mW/ cm^2
RF/EM	
GSM	0.1 μW/ cm^2
Wi-Fi	0.001 mW/ cm^2
Solar	
Outdoor	10 mW/ cm^2
Indoor	< 0.1 mW/ cm^2
Acoustic	
75 – 10 dB of noise	0.003 – 0.96 μW/ cm^2
Human Body Sources	
Body heat	0.2 – 0.32 W (neck)
Walking	5 – 8.3 W

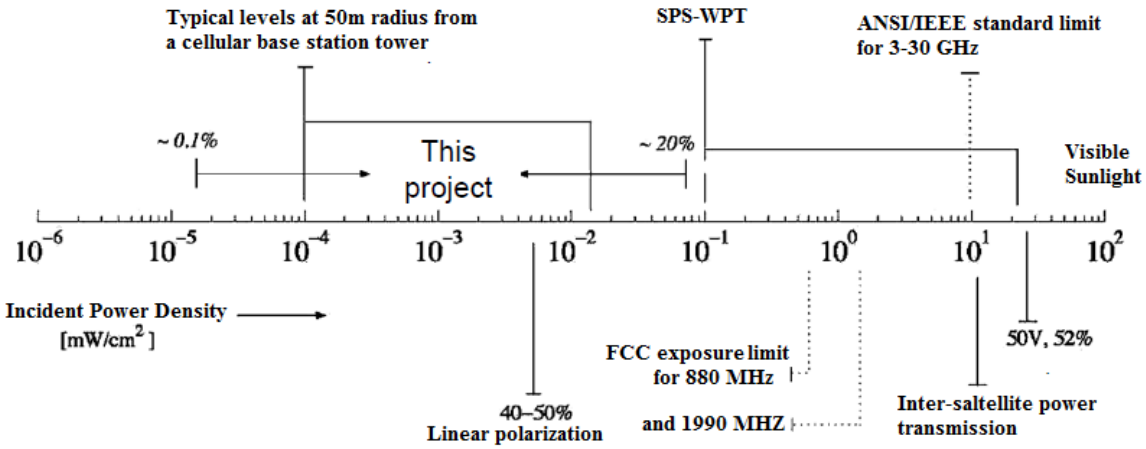

Fig. 2.2.1 Diagram of various microwave power sources and their typical power density levels. Also shown is the range of expected power densities used in the solar power satellite (SPS) and wireless power transmission (WPT) applications. The range of power densities for this work is indicated.

In Fig. 2.3.1 we see that the measured values of any kind of environment, at ground level, have a greater variation of power density, this is due to ground level, not always line of sight is obtained. For distances ranging from 25m to 100m from a GSM base station, power density levels ranging from 0.1mW/m2 to 1.0mW/m2 may be expected for single frequencies.

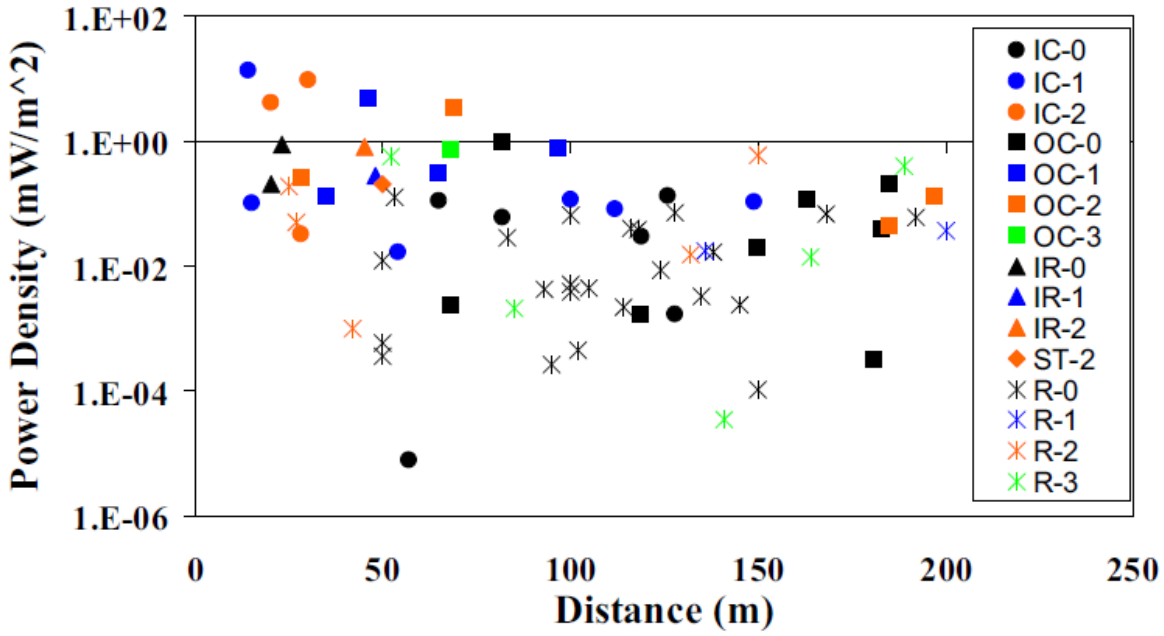

Fig. 2.3.1 Measured GSM-900 peak power density levels as a function of distance to the nearest base station. Data is taken from. Code "XY-a" indicates area and measurement site characteristics. XY: IC=Inner City, OC=Outer Country, IR=Industrial area, ST=Small Town, R=Rural or country-side are. "a": 0=outdoors on the ground, 1=outdoors on roof, terrace or balcony, 2=indoors, close to windows, 1.5m or less, 3=indoors, not close to windows.[8]

Figure 2.3.2 shows measurements over the entire 935-960 MHz band of the summed power density as a function of distance, we can conclude that between 25m and 100m, for indoor and outdoor environments, a high density power with values between 3.0 and mW/m2 0.3mW/m2 is expected. The measures over the entire frequency band are closely related to the traffic density at the moment of measurement, these measurements can vary by a factor form one to ten when compared with the measurements of a single Frequency (Fig. 2.3.1). Although the frequency of GSM-1800 band has doubled the GSM-900 band and therefore the free space loss has been quadrupled, ICNIRP (International Commission on Non-Ionizing Radiation Protection) exposures have only doubled. As for GSM-900, the actual exposures are well below the ICNIRP limits, we expect that power density levels for GSM-1800 are similar. This can be justified by measurements carried out in UK [9] and in Australia [10] for a mix of GSM-900/1800 base stations. From Figure 2.3.3, we can conclude that the power density measurements for GSM-900 and GSM-1800 are, up to 100 m, in the same order of magnitude.

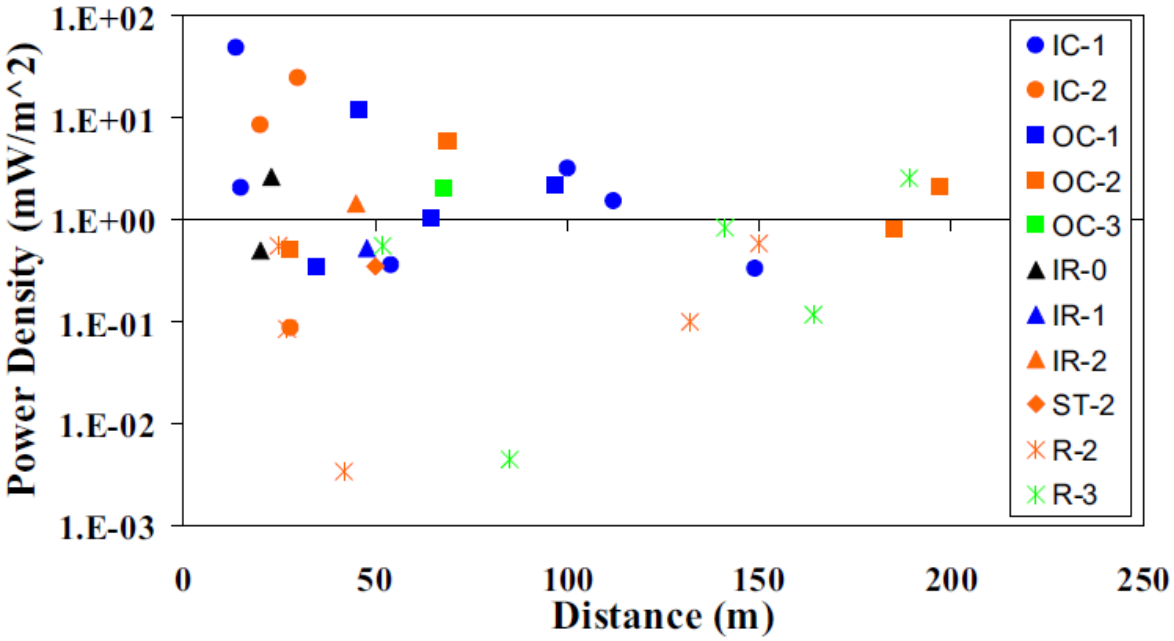

Fig. 2.3.2 Measured GSM-900 summed power density levels as a function of distance to the nearest base station, without data taken on ground level [8].

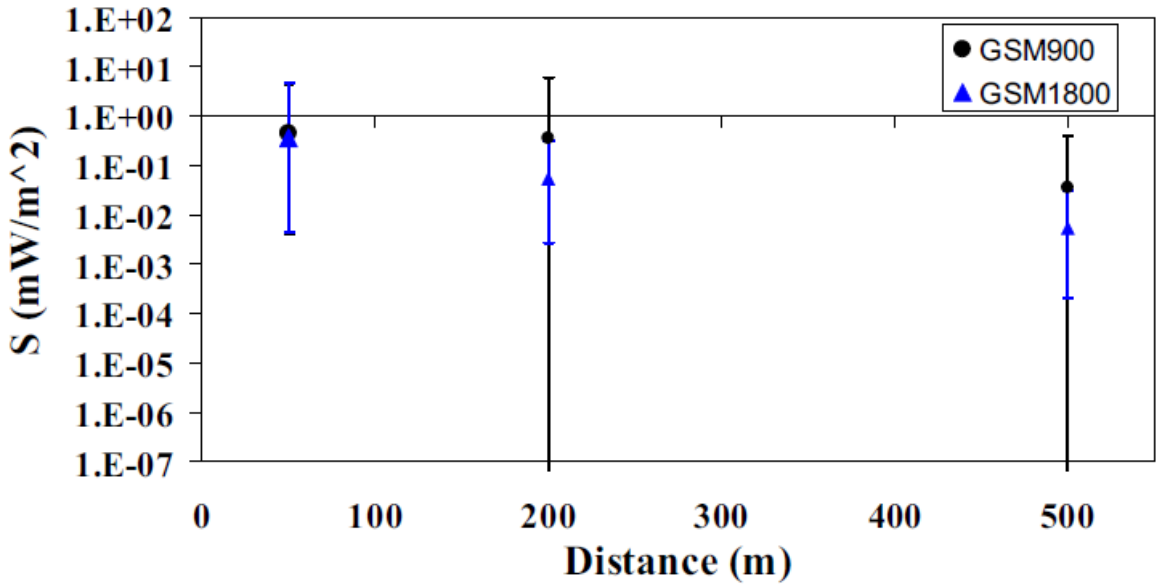

Fig. 2.3.3 Measured summed power density levels as a function of distance to the nearest GSM-900 and GSM-1800 base station [8].

If we refer to the 2.4 GHz band, whose efficiency in the environment is very high, Wi-Fi wireless local area networks (WLAN) applications are also useful with this concept. A WLAN router, transmit much less power than a GSM base station [8]. But because a router is confined to indoor environments and also that the distance would be much lower, reflections and low path loss may help to achieve suitable levels of power density. Fig.

2.3.4 shows the power density as a function of distance from the router. Although, during measurements of traffic levels were very low, we see that the power density levels are at least one order below the measurements obtained from GSM base stations.

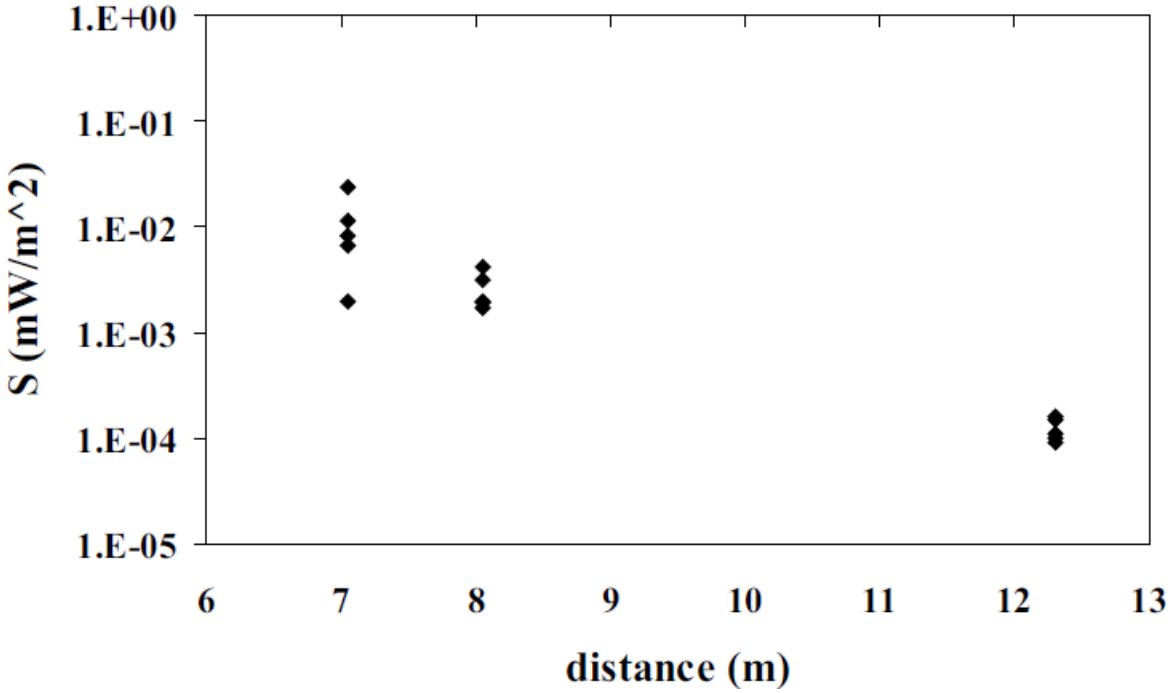

Fig. 2.3.4 Measured WLAN peak power density levels as a function of distance to the WLAN router [8].

2.4 Recent Technologies of Rectenna.

As explained above, a rectenna is a system that basically consists of a receiving antenna and a rectifier circuit which converts RF or microwave power into useful DC power. Fig. 2.1.2 shows the Schematic of a rectenna and associated power management circuit. The incident waves within a certain spectral range are received by the antenna, coupled to the rectifying device (diode in this case), and the low-pass filter (LPF) ensures that no RF is input to the power management circuit. A controller provides input to the power management circuit, which enables storage of the received energy over time, and delivery of DC power at the level and time when it is needed. This work will focus over the receiving antenna, the matching circuit and the rectifier circuit.

In recent years, a new approach to the use of rectennas has been reached and compared to other periods of microwave power transmission (MPT), where only high-power applications were developed (such as helicopter powering [1], solar-powered satellite-to-ground transmission [11], mechanical actuators for space-based telescopes [12], driving

motor [13], etc.), currently the develop of low-power applications is evolving. Rectennas implementing Ultra wideband (UWB) and narrow-band (essentially single frequency) antennas with smaller dimensions and new rectifier circuits configurations with new detectors that allow better performance are been used[14]. Self-powered sensors, short distances RFID tags, biomedical implants and energy harvesting devices, are some of the new low-power applications.

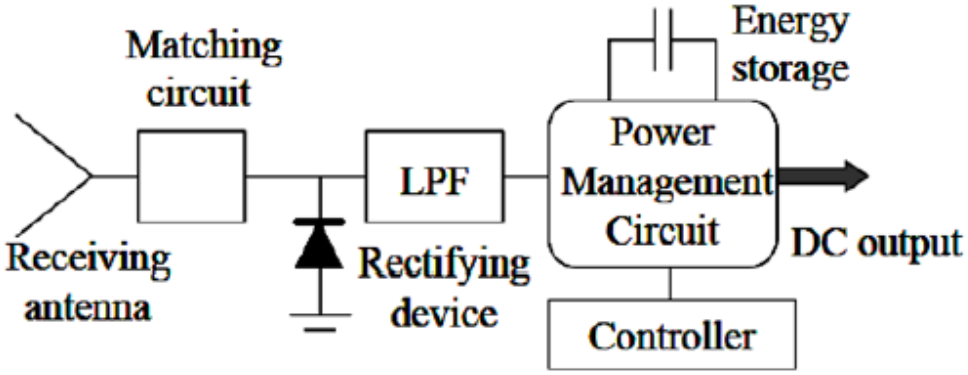

Fig. 2.4.1 Basic rectenna schematic with the power management system

Chapter 3

Antenna Design

In this chapter is described the design process, simulations and fabrication of an Ulta-WideBand antenna that operates from 900 MHz up to 6GHz. First we start with a brief explanation of the main design parameters of an antenna then we briefly explain the advantages of using UWB and microstrip antennas in these applications. Also a brief introduction of the software used for the design and simulations stages, as well as the method used for the simulator will be presented.

A parametric study of semicircular printed monopoles is included. Then we will explain how making some changes to the shape of the ground plane and the radiating patch of the antenna can improve the performance. After all the parametric simulations a final antenna version was chosen and subsequently built. Some pictures of the milling machine and the procedures after the milling are shown.

To improve the size of the antenna, a final version with some miniaturization techniques was built and the parametric simulations are included in a final study.

3.1 Antenna characteristics

To design an antenna, previously it is necessary to establish certain performance parameters that will be our goals in the design process and that are specific to our application.

3.1.1 Bandwidth

Bandwidth can be expressed as the range of frequencies over which the antenna characteristics are acceptable. In the case of broadband antennas, the bandwidth is often denoted as the ratio between the highest and lowest operating frequency. For example, 6:1 means that the higher frequency is six times greater than the lowest frequency.

3.1.2 Radiation Pattern

Is the mathematical representation or graphical representation of the radiation from an antenna as a function of spatial coordinates. Some of the properties of radiation are power flux density, radiation intensity, field strength, phase and polarization directivity, being the most important the spatial two and three dimensional radiation energy. A stroke of the power received at a constant radius is called power pattern. On the other hand, a plot of the spatial variation of an electric field (or magnetic) at a constant radius is called field amplitude pattern.

In practice, a three dimensional representation is obtained through various cuts of two-dimensional patterns. However for most practical applications, only some measures in terms of THETA for certain values of PHI and some measures in term of PHI for some values of THETA give us more useful information.

3.1.3 Radiation Power Density

Electromagnetic waves are used to carry information from one point to another through a wireless medium or through a guide structure, then it is natural to assume that the power and energy are associated with electromagnetic fields. The amount used to describe the power associated with an electromagnetic wave is the instantaneous Poynting vector

$$\mathcal{W} = \mathcal{E}\ x\ \mathcal{H}$$

$$\mathcal{W} = instantaneous\ Poynting\ vector\ \left(\frac{W}{m^2}\right)$$

$$\mathcal{E} = instantaneous\ Poynting\ vector\ \left(\frac{V}{m}\right)$$

$$\mathcal{H} = instantaneous\ magnetic\ field\ intensity\ \left(\frac{A}{m}\right)$$

Since the Poynting vector is a power density, the total power crossing a closed surface can be obtained by integrating the normal component of Poynting vector on this surface.

$$\wp = \oiint_S \mathcal{W}.ds = \oiint_S \mathcal{W}.\check{n}\, da$$

$$\wp = instantaneous\ total\ power\ (W)$$

$$\check{n} = unit\ vector\ normal\ to\ the\ surface$$

$$da = infinitesimal\ area\ of\ the\ colsed\ surface\ (m^2)$$

3.1.4 Radiation Intensity

The radiation density in a specific direction is defined as the power radiated by an antenna per unit solid angle, is a far-field parameter and is the product of multiplying the intensity of radiation by the square of the distance.

$$U = r^2.W_{rad}$$

$$U = radiation\ intensity\ (\frac{W}{unit\ solid\ angle})$$

$$W_{rad} = radiation\ density\ \left(\frac{W}{m^2}\right)$$

The radiation density in a certain direction is defined as the power radiated by an antenna per unit solid angle, is a far-field parameter and is the product of multiplying the intensity of radiation by the square of the distance.

$$P_{rad} = \oiint_\Omega U d\Omega = \int_0^{2\pi} \int_0^{2\pi} U.\sin\theta\, d\theta\, d\phi$$

$$d\Omega = element\ of\ solid\ angle = \sin\theta\, d\theta\, d\phi$$

In an isotropic antenna U is independent of the angles THETA and PHI.

$$P_{rad} = \oiint_\Omega U_0 d\Omega = U_0 \oiint_\Omega d\Omega = 4\pi U_0$$

$$U_0 = \frac{P_{rad}}{4\pi}$$

3.1.5 Directivity

In an isotropic antenna U the directivity is independent of the angles THETA and PHI. Directivity of an antenna is the ratio between the intensity of radiation in one direction from the antenna with the radiation intensity averaged over all directions. The average radiation level is equal to the total radiated power divided by 4PII. If the direction is not specified it is assumed the maximum intensity of radiation. In other words, the directivity of an antenna is not isotropic in a particular direction is equal to the ratio between the intensity of radiation with the radiation of an isotropic antenna.

$$D = \frac{U}{U_0} = \frac{4\pi U}{P_{rad}}$$

If the direction is not specified, it implies the direction of the maximum radiation intensity (maximum directivity) expressed as:

$$D_{max} = D_0 = \frac{U_{max}}{U_0} = \frac{4\pi U_{max}}{P_{rad}}$$

$$D = directivity\ (dimensionless)$$

$$D_0 = maximum\ directivity\ (dimensionless)$$

$$U = \text{radiation intensity (W/unit solid angle)}$$

$$U_{max} = \text{maximum radiation intensity (W/unit solid angle)}$$

$$U_0 = \text{radiation intensity of isotropic source (W/unit solid angle)}$$

$$P_{rad} = \text{total radiated power (W)}$$

3.1.6 Polarization

Polarization of an antenna can be defined as the polarization of the radiated fields measured or "seen" from far fields, some of the typical classifications are the linear polarization and circular (Right / Left Hand).

Because of the reciprocity theorem, antennas transmit and receive in the same way, then a vertically polarized antenna will communicate with another antenna vertically polarized and an horizontally polarized antenna will communicate with another horizontally polarized antenna, if, for example, a horizontally polarized antenna try to communicate with another whose polarization is vertical, there won't be communication at all.

To describe in general terms the loss of polarization we use the Polarization Loss Factor (PLF):

$$PLF = \cos\phi^2$$

The PFL describes the loss ratio in function of a rotation angle between two linearly polarized antennas.

A circular polarization is desired in many applications because there is no loss of polarization as a function of antenna rotation angles.

If, for example, a circularly polarized antenna receives a linearly polarized antenna signal(or vice versa), we must recall that the circular polarization is actually the product of two linearly polarized waves orthogonal to each shifted 90 degrees, then the receiving antenna will receive only the linear part which is half of the total power.

$$PLF(linear\ to\ circular) = 0.5 = -3dBm$$

3.1.7 Axial ratio

The axial ratio is a parameter used to quantify the polarization of an antenna and to denote deviations from a desired polarization and can be defines as the ratio of orthogonality of E fields components. When an antenna has a perfect circular polarization, the axial ratio is 1 (or 0 dB), because you have E-field components of the same magnitude, if it's an antenna with elliptical polarization, the axial ratio is greater than 1 and if it is a purely linear polarized antenna, the axial ratio tends to infinity because one of the components of E field is zero. The value of the axial ratio is degraded at a greater distance of the mainbeam.

3.1.8 Gain

The term gain describes how much power is transmitted in the direction of peak radiation to that of an isotropic source. The gain of an antenna is defined as the ratio of power delivered to the antenna and the power that is actually radiated. Ideally, the radiated power is equal to the received power, but in real specifications of antennas, due to various types of losses (conduction losses and dielectric losses) as well as mismatching losses, the ideal value is never obtained.

3.2 UWB Antennas

Broadband and UWB antennas date back to the earliest days of radio [15]. The wide scale commercial deployment of ultra wideband (UWB) systems has led to increased interest in UWB antenna design. The requirements imposed by UWB systems place stringent demands on UWB antennas. For example, the spectral and impedance matching properties of a UWB antenna influence on an overall UWB system design. A well-designed UWB antenna can contribute to system performance by notching out undesired frequencies.

UWB wireless technology is most thought for some application like:

- Very high-data-rate and short-range wireless communication systems
- Coding for security and low probability of interception
- Rejection of multipath effect
- Modern radar systems
- Energy harvesting
- Self powering devices

Printed antennas, commonly fabricated on FR4 substrate, are very cost effective, which is ideally suited for UWB technology-based low-cost systems.

3.2.1 Microstrip Antennas

Microstrip antennas date back to the 50's when they were patented, but it is in the 70's when they receive considerable attention [16]. With the development of the high data rate wireless communication systems, antenna engineers are faced with increasing demand for smaller antennas which still retain broadband characteristics.

A microstrip antenna is formed basically by a dielectric substrate between two metal layers, one layer is the antenna and the other is the ground, Fig. 3.2.1.1 shows the basic configuration of a microstrip antenna

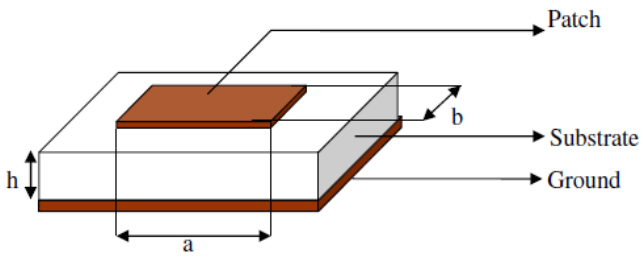

Fig. 3.2.1.1: basic layers of a microstrip antenna

Microstrip antennas, also known as patch antennas, performance is affected by the patch geometry, substrate properties and feed techniques, they often have the radiating elements and the feeding line etched in the dielectric substrate, they have its maximum radiation in the normal direction of the plane of the antenna that is achieved with an appropriate excitation below the antenna.

There are many types of substrate with dielectric constant values usually in the range of 2.2 <ER <12. Thick substrates with low dielectric constants are desired because they have higher bandwidth efficiency at the cost of a larger antenna size. On the other hand thin substrates with a high dielectric constant are desired in applications of microwave circuitry because they minimize unwanted coupling and radiation, and also because they allow to design smaller antennas. Since the microstrip antennas are closely linked to microwave circuits, a compromise between efficiency, bandwidth and size is necessary [16].

In recent years, printed planar monopole antennas have become very popular [16] and some of the main advantages of these antennas are:

- Low profile
- Low cost
- Light weight
- Ease of fabrication and installation
- Large bandwidth
- Radiation properties, wide impedance bandwidth and nearly omnidirectional azimuthal radiation pattern)
- Some of the various applications are covered with fewer or with a single antenna.

3.2.2 Feed mechanisms

Most of the performance and complexity of the design of a microstrip antenna depends on how the antenna patch will be fed. We can classify the techniques of feeding in three large groups.

- *Directly connected*: in this technique, a connection is made directly to the radiator element. For example, a microstrip line or a coaxial cable. This technique is very efficient in thin undertreated and one advantage is that the feeding line and the patch antenna are on the same plane, so it becomes a planar construction. In the case of a coaxial cable, it connects to the patch antenna through a hole in the substrate and the outer shell is grounded by merging it with the ground plane of the antenna.
- *Aperture Coupling*: This technique was introduced to overcome the technical problems of the directly connected feeding technique. It basically consists of two

substrates separated by a ground plane; in the bottom of the lower substrate, there is a microstrip line whose energy is coupled to the patch that is in the top of the upper substrate through a hole in ground plane. This feeding is the most difficult to manufacture and has a narrow bandwidth, but it is easier to model and has moderate spurious radiation [16].

- *Proximity Coupling*: The technique of proximity coupling consists of a power line located between two substrates, at the bottom of the lower substrate is the ground plane, and at the top of the upper substrate is the patch. Of the four feeding techniques, proximity coupling is the one with the higher bandwidth, is relatively simple to model and the spurious radiations are low, however its manufacturing is more difficult.

3.2.3 Software

For the stage of physical design and simulation, the Ansoft HFSS 11 software has been used. In order to generate an electromagnetic field solution, HFSS employs the finite element method. Fig. 3.2.1.1 shows the main window of the HFSS11; in the right side, a preview of the design is shown, the middle part, lists the components that make up our design, such as, solids, sheets, and planes. The left side shows the configurable features of the project such as the frequency sweep settings and simulation results.

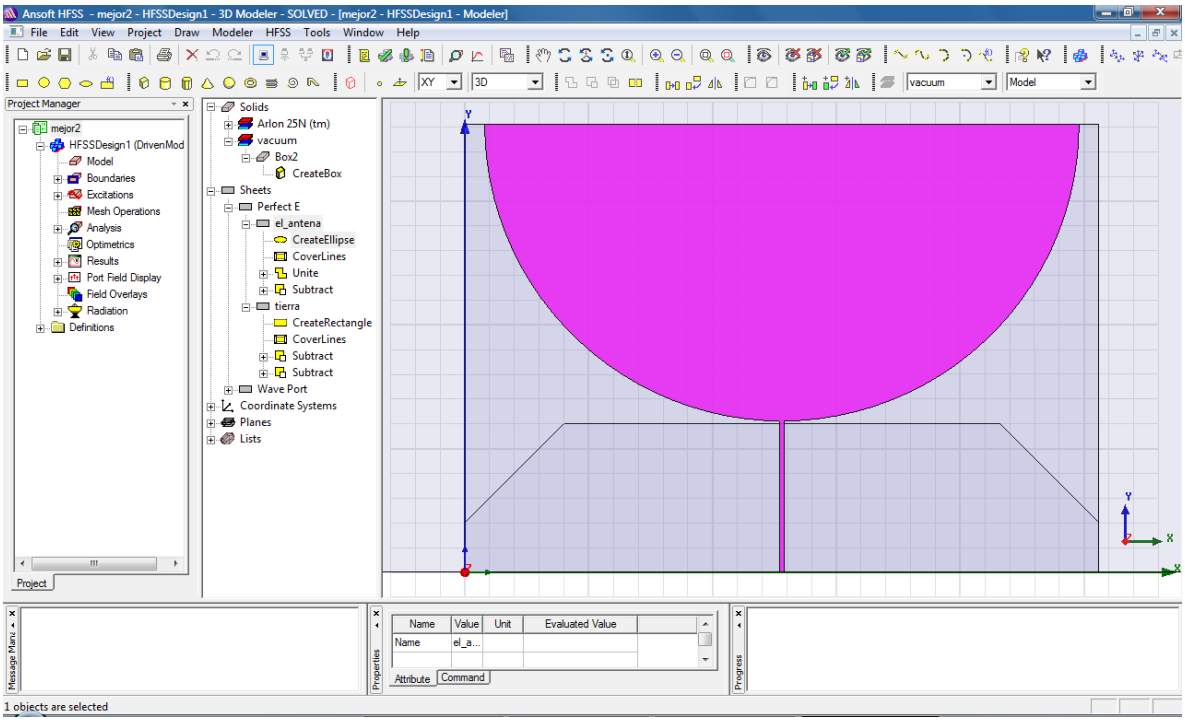

Fig. 3.2.1.1: Main HFSS11 window.

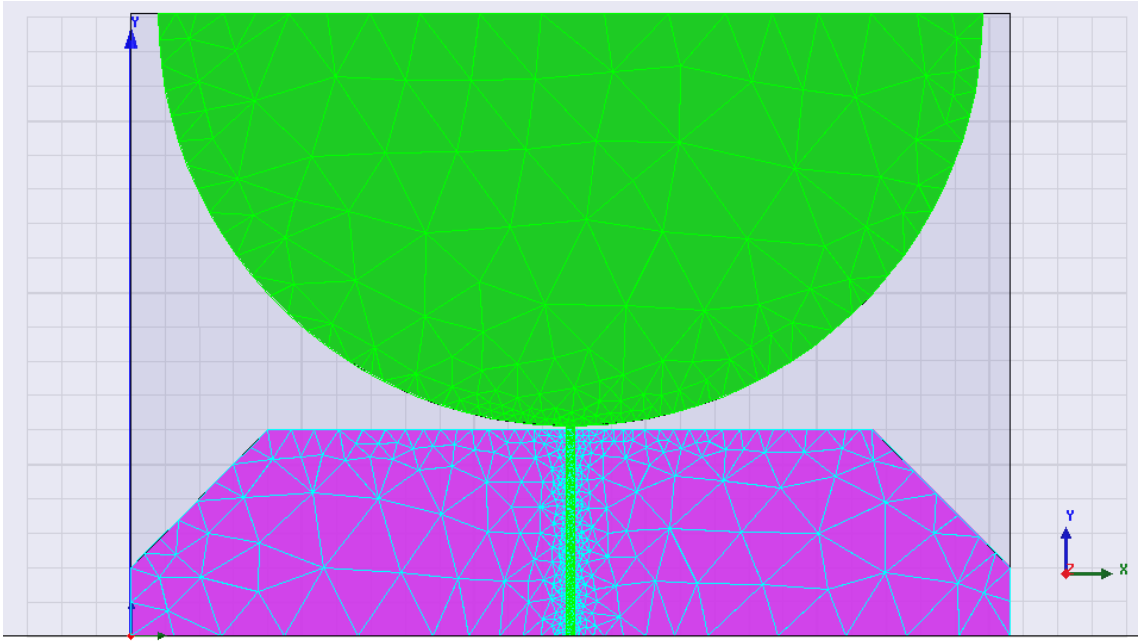

Figure 3.2.1.2: Generated mesh to solve the antenna design employing the finite element method

In general, the finite element method divides the full problem space into thousands of smaller regions and represents the field in each sub-region (element) with a local function. One feature of this method is that in areas of interest, the resolution of elements (Mesh) becomes denser in order to obtain more accurate predictions. Fig. 3.2.1.2 shows an example of how the antenna is divided into smaller sections and then apply the finite element method and Fig. 3.2.1.3 shows the higher density of elements.

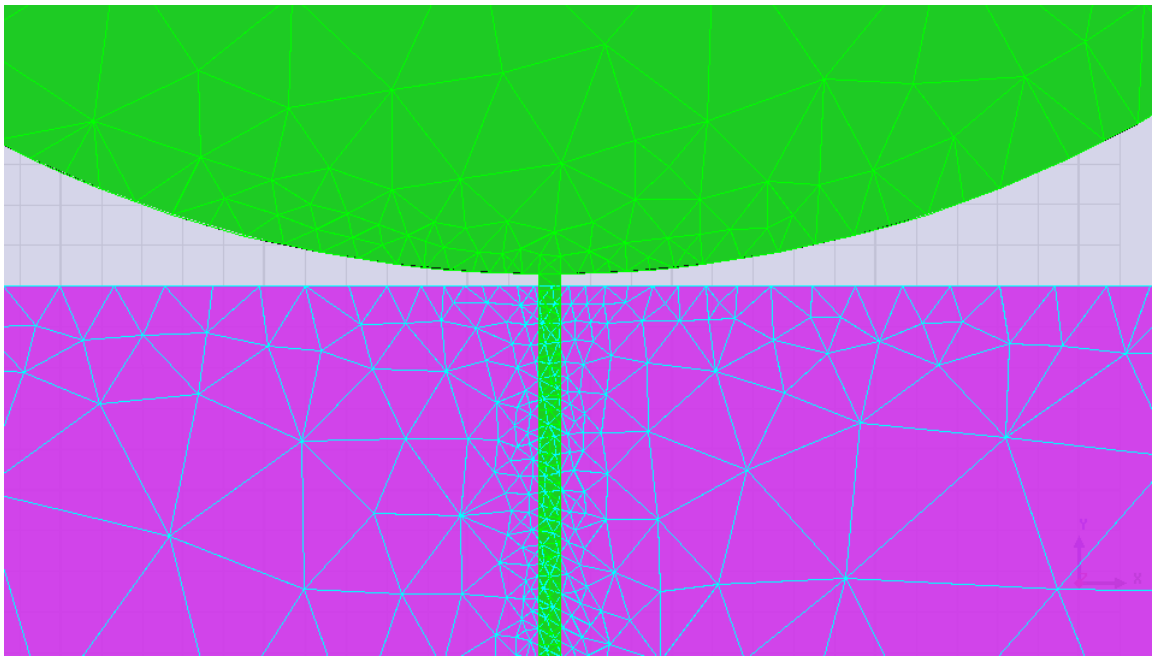

Figure 3.2.1.3: Higher density of elements to obtain a more accurate result

3.3 Antenna Simulations

In this section, we will explain the process for the design and choice of two UWB antennas that were subsequently built. A bandwidth covering form 900 MHz - 6 GHz (so that the main 900/1800 GSM downlink bands and the 2.4 - 2.5 GHz ISM band, were covered) and not very large physical dimensions were the main characteristics desired for our antennas. The results of the simulations and parametric studies will be shown and analyzed. According to these studies, the best antenna was chosen and then, a modification to the ground plane was made; this analysis will be detailed later. After this last modification, the antenna was built and we will call it, from now on, base-antenna.

In order to reduce the size of the base-antenna, but maintaining the bandwidth, miniaturization techniques were applied, a parametric study of this process will be included and explained, to be then built; we will call this antenna, from now on, size-improved antenna.

For the design of our antennas, we have started with a single shape, and, according to the simulation results and references, we have tuned some parameters to reach the best possible performance. The table 3.3.1 shows the parameters of the available substrate.

Table 3.3.1: Dielectric parameters

	Arlon 25N (A25N)
Er	3.38
TanD	0.0025
H	0.508mm
Cond (copper)	5.813×10^7

3.3.1 Base Antenna

For antenna design we have not followed a parametric design procedure. The design has started with a pre-existing half disc antenna and we have adapted it to our needs through simulations. We have varied the parameters shown in Fig. 3.3.2.1. In general terms, the main differences between a full disc antenna and the half disc are that low frequency limit of the band increases slightly, but the phase response remains linear, also, the received peak amplitude is also deceased by about 20% from the disc antenna [18]. This is not a large penalty for obtaining the substantial shortening of the height to half of the original disc antenna. A small size and a broadband antenna are our main goals.

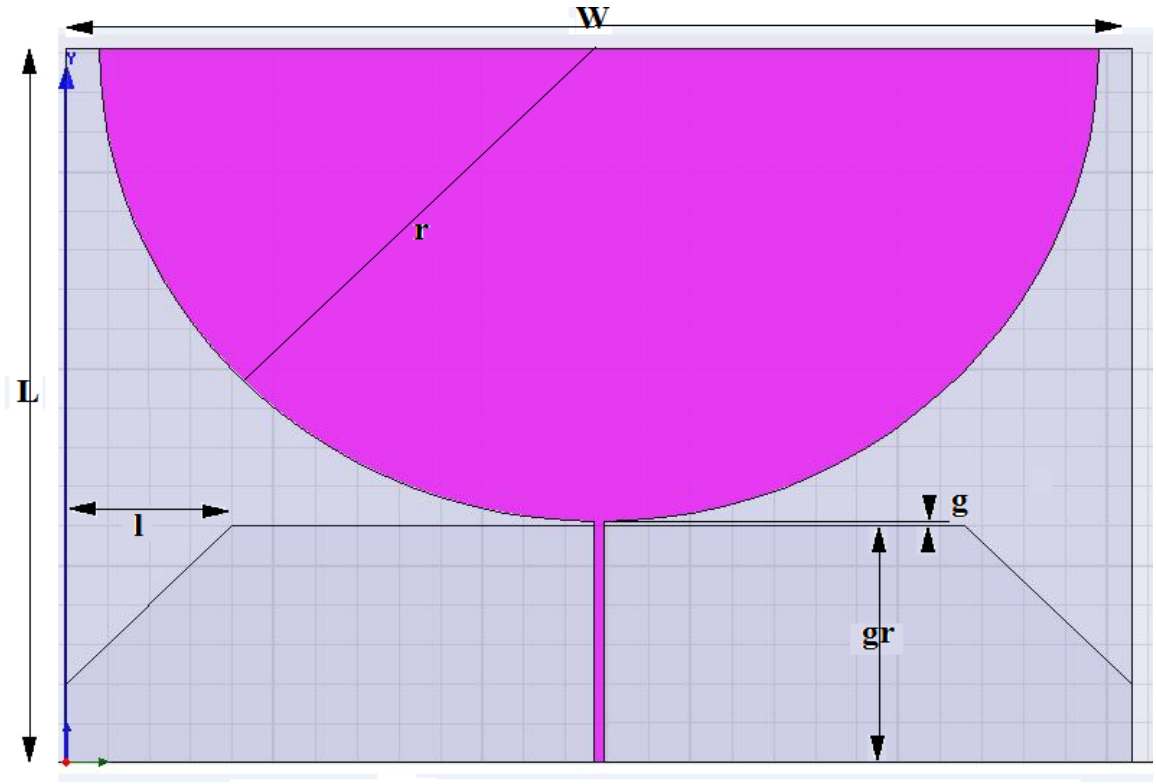

Fig. 3.3.1.1: 2D view of the base-antenna.

As if it were a circular monopole patch, the radius r of the circle is the main parameter to optimize for the lowest return loss and widest bandwidth. We will do a parametric sweep of "r" while the other parameters are kept constant. Fig. 3.3.1.1 shows the behavior of changing this parameter; we can observe that as the radius of the circle increases, the lower frequency decreases.

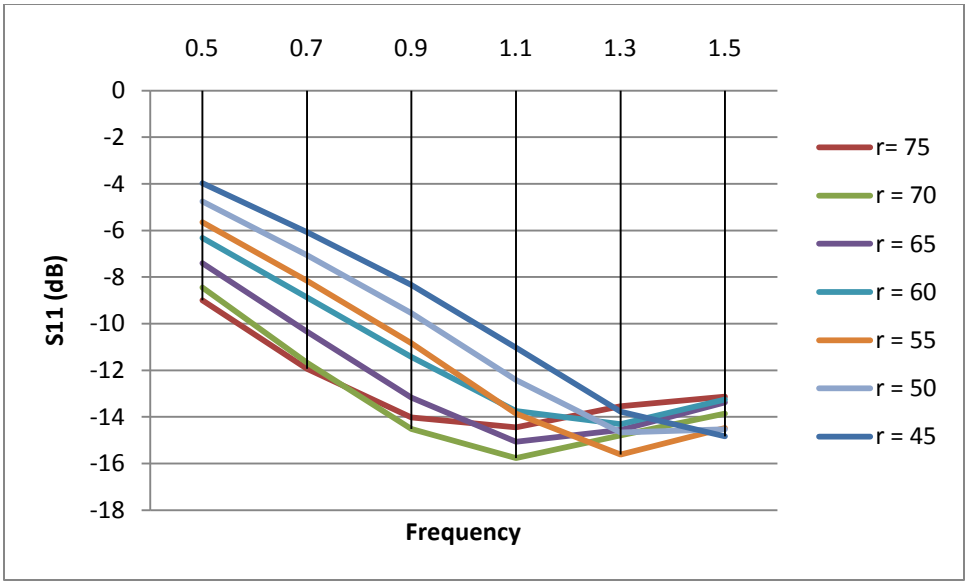

Fig. 3.3.1.2: low-frequency return-losses as a function of the "a" parameter

The following parameter to tune is the gap between the patch and ground plane ("g"). Parameter is stated to:

- Have positive value if the patch is at a higher level than the ground layer.
- Have null value when the ground plane ends where the patch begins.
- Have a negative value if the patch and ground layer overlap.

Since the simulation software does not accept negative values, we have denoted the parameter "h" as "g + gr", and the ground plane height is 30mm.

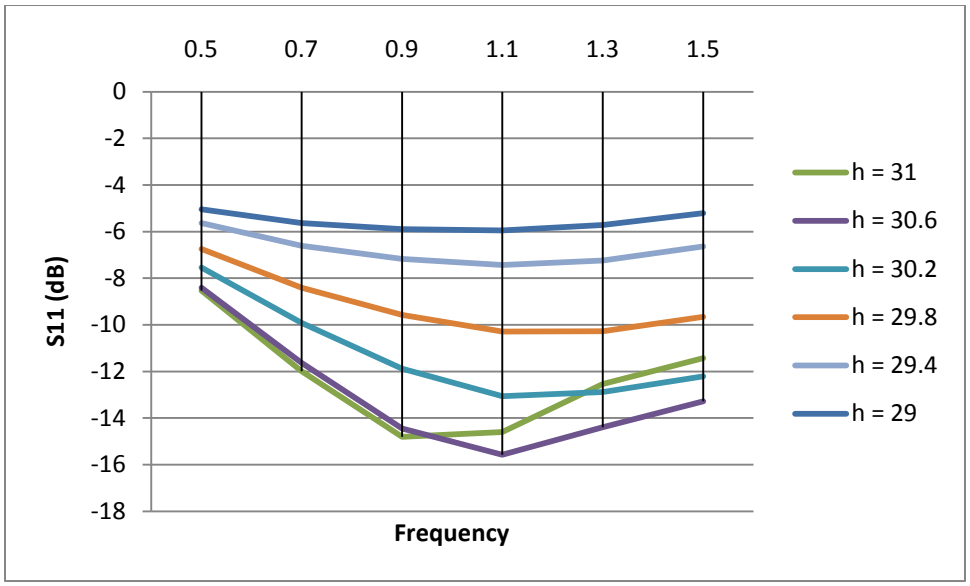

Fig. 3.3.1.3: low-frequency return-losses as a function of the "a" parameter

From Fig. 3.3.1.3 we can conclude that the best performance value is h = 30.6 mm (g = 0.6 mm)

3.3.2 Ground Modification

To improve the bandwidth of the antenna, we have removed the upper corners of the ground plane and we will vary them to reach the best performance. Fig. 3.3.2.1 shows the results of the variation of the "l" parameter. It also shows that "l" has not considerable effect at low frequencies. But at frequencies above 1 GHz is a noticeable difference.

Fig.3.2.2.3 shows the radiation patters for each frequency and Fig. 3.2.2.4 represents the gain pattern of the base-antenna

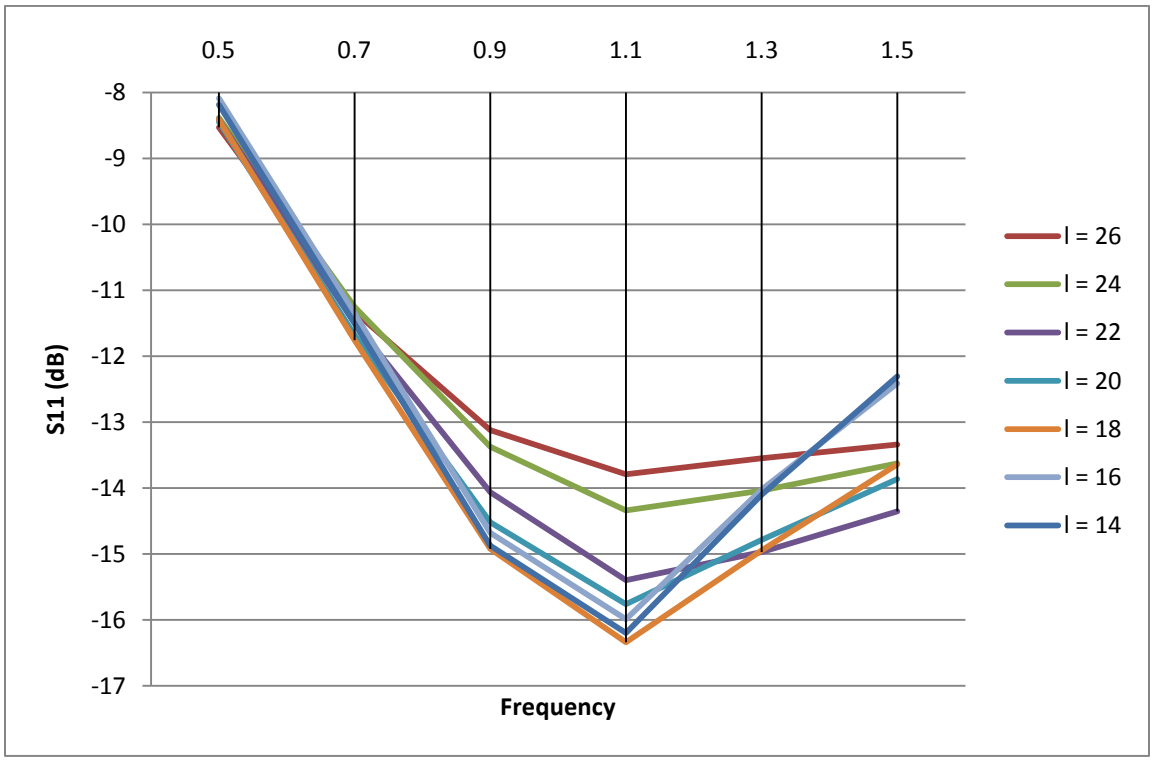

Fig. 3.3.2.1: low-frequency return-losses as a function of the "l" parameter

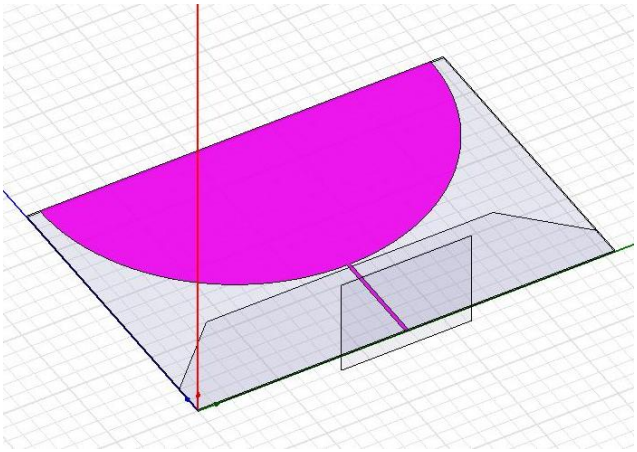

Fig. 3.3.2.2: 3D view of the base-antenna (HFSS11)

Table 3.3.2.1: Final values for the base-antenna, the name of the values are taken from Fig. 3.3.2.2.

3.3.3 Miniaturization Techniques

This section is intended to reduce the size of the design that we had previously. In [19], a series of procedures that aim to alter the current distribution at the antenna surface by inserting a slot is shown. As we have a different antenna (in the paper is a rectangular antenna), we cannot guide from the slot dimensions that are presented in this paper.

To overcome this, we'll perform simulations by varying some parameters to finally choose appropriate slot values.

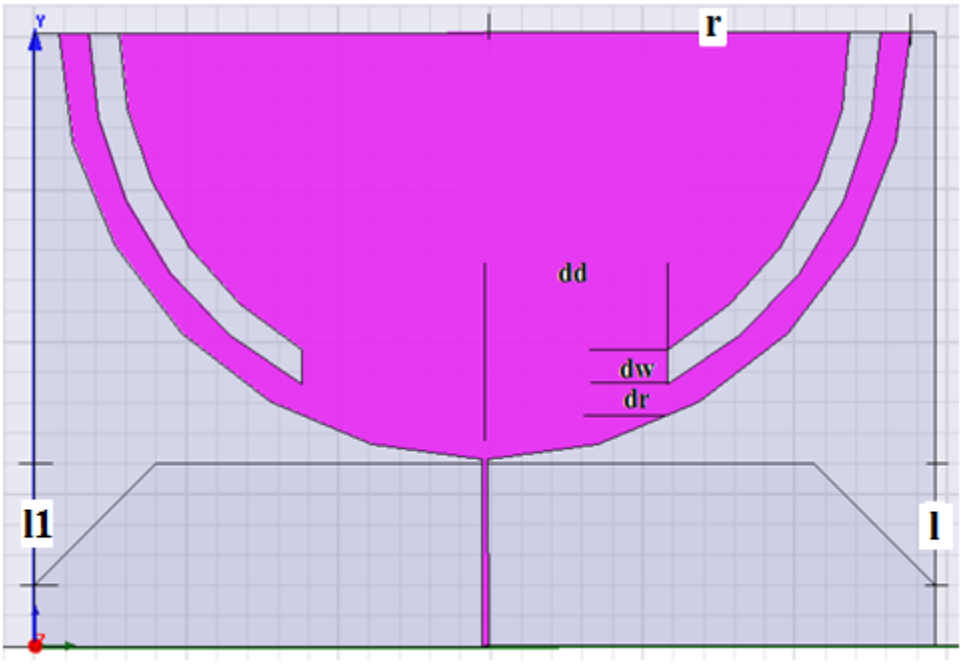

Fig. 3.3.3.1: Slotted antenna and its parameters

Fig. 3.3.3.1 shows the first slotted antenna prototype. The dimensions of the slot are denoted with the "dd", "dr", "dw" variables. We will vary each one of these parameters in a given range to see how they affect the antenna performance.

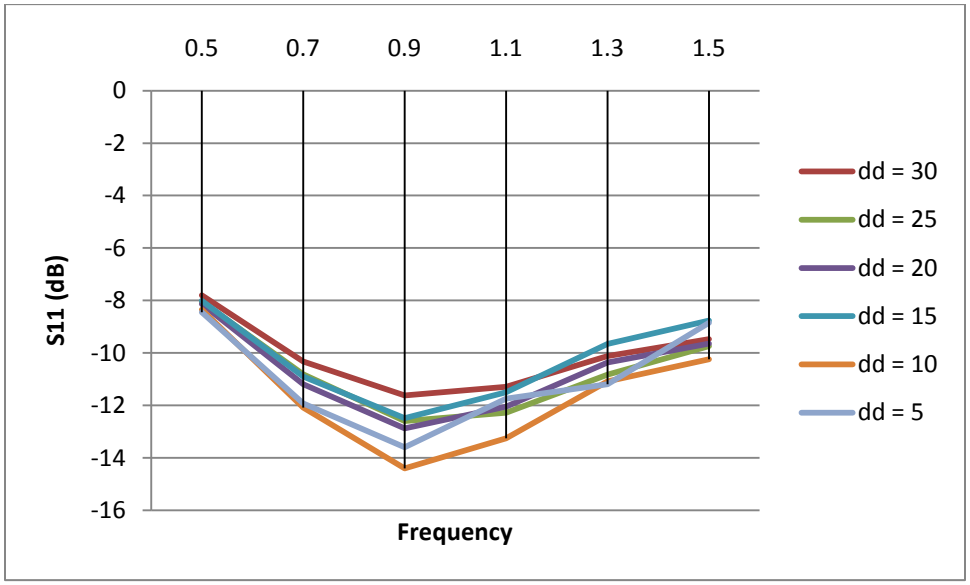

Fig. 3.3.3.2: low-frequency return-losses as a function of the “dd” parameter

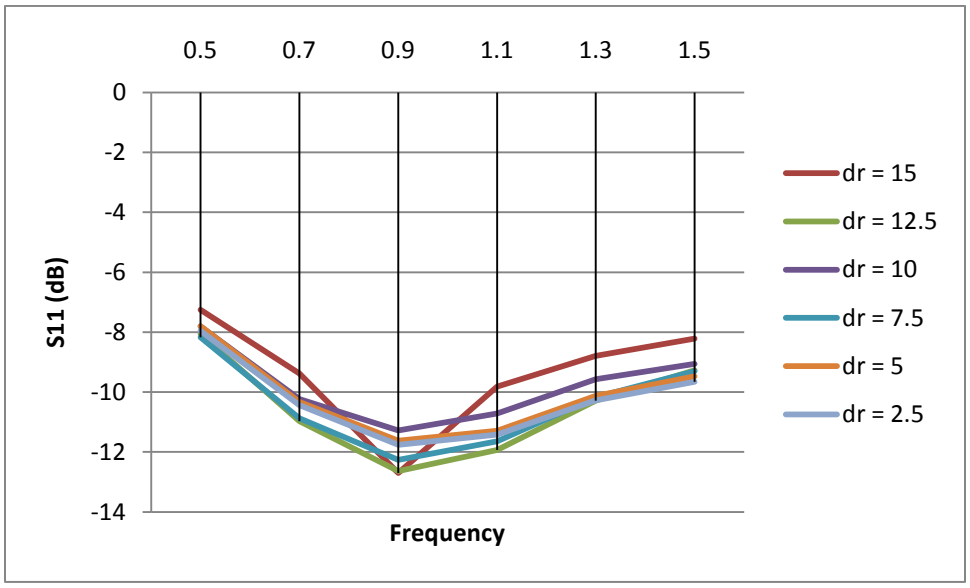

Fig. 3.3.3.3: low-frequency return-losses as a function of the "dr" parameter

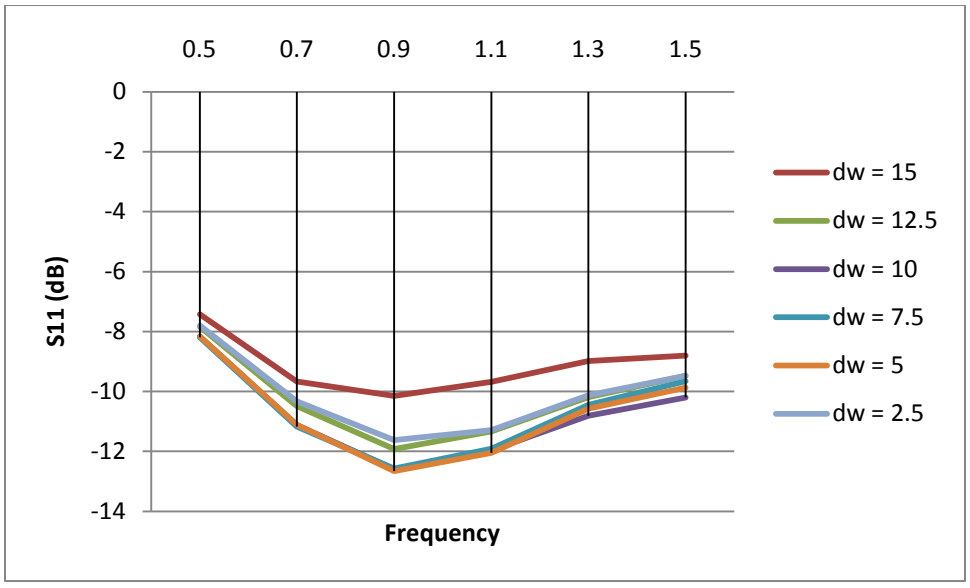

Fig. 3.3.3.4: low-frequency return-losses as a function of the "dw" parameter

After seeing these parametric simulations, we can observe that the slot length has effect on the impedance matching, especially at low frequencies. The width and location of the slot slightly influence the low frequencies. In general, all parameters related to the slot have some influence in the impedance matching.

The next step is to reduce overall the size of the antenna; in this step reduction will be done by reducing the radius "r" of the semi-circle. Because of the total dimensions of the substrate are as a function of the radius, they are automatically accommodated after a radius change. Fig. 3.3.3.5 shows how return loss varies by changing this parameter.

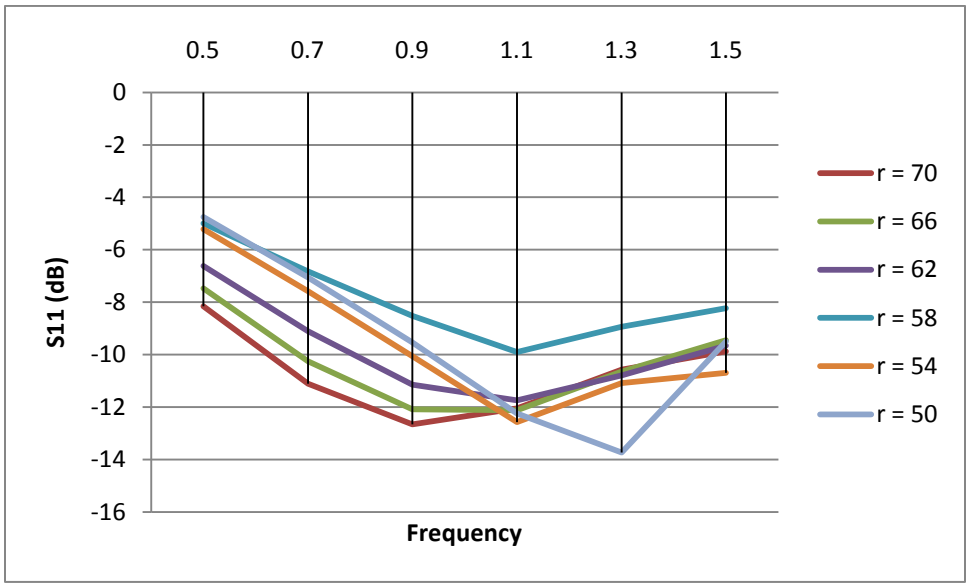

Fig. 3.3.3.5: low-frequency return-losses as a function of the "a" parameter

After seeing the results in Fig. 3.3.3.5, we have decided to reduce the radius "r" from 70mm to 60mm, with this adjustment, dimensions of the substrate, have been reduced from 148mm x 100mm to 120mm x 90.6, 19% and 9.4% respectively. Because of the change of th antenna, the response is not the same, but as we know the behavior of each parameter we have adjusted them and the final values now are: dd:14mm, dr:10mm and dw:7mm.

The next antenna design will intend to reduce even more the previous antenna design by inserting an angle cut as we know that current distribution is supposed to concentrate close to the slot (we will verify this in section 3.3.4), then, we will try to concentrate it in one slot. The next step is to make an angle cut to the patch. Fig. 3.3.3.6 shows the way we will do this, we will use the middle line of our antenna as a reference, and moving to the left, we will find the proper angle.

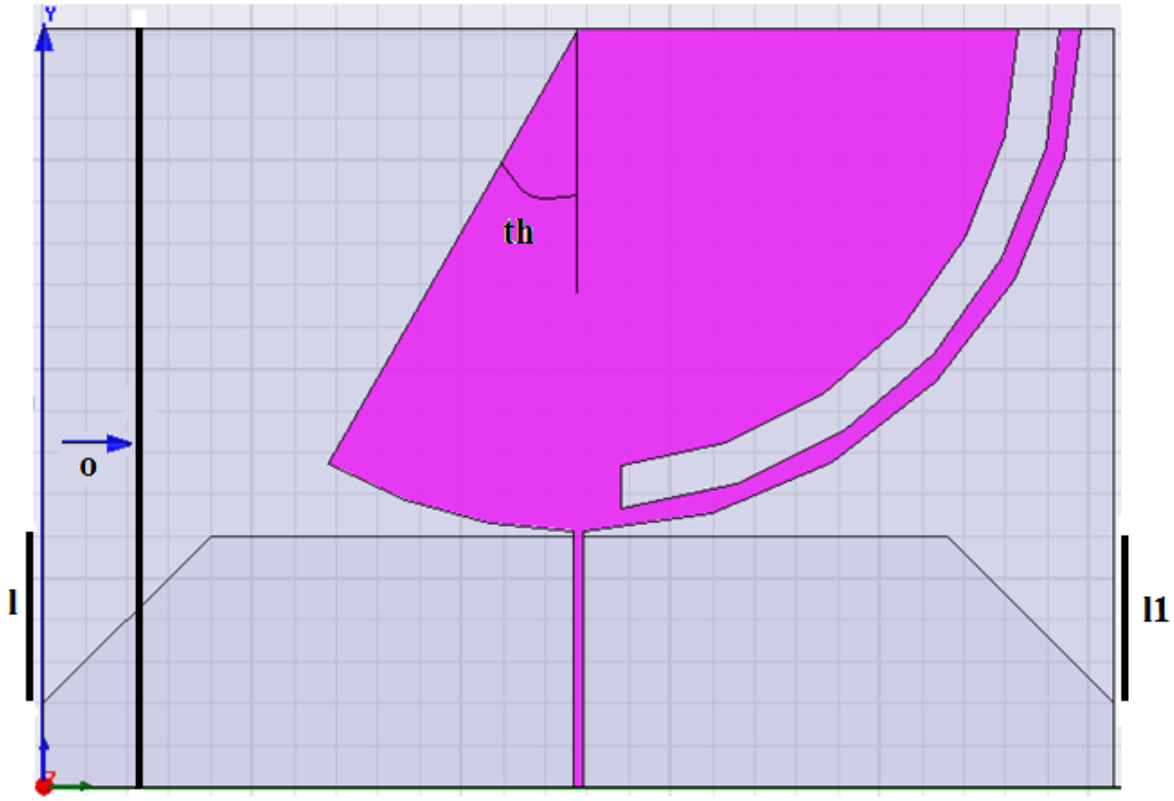

Fig. 3.3.3.6: shows the antenna and the "th" parameter

From Fig. 3.3.3.7, we can conclude that as the angle increases, frequencies above 1GHz change their performance dramatically. Lower values of "th" are desired, because they would provide us more free-area in the left side of the antenna.

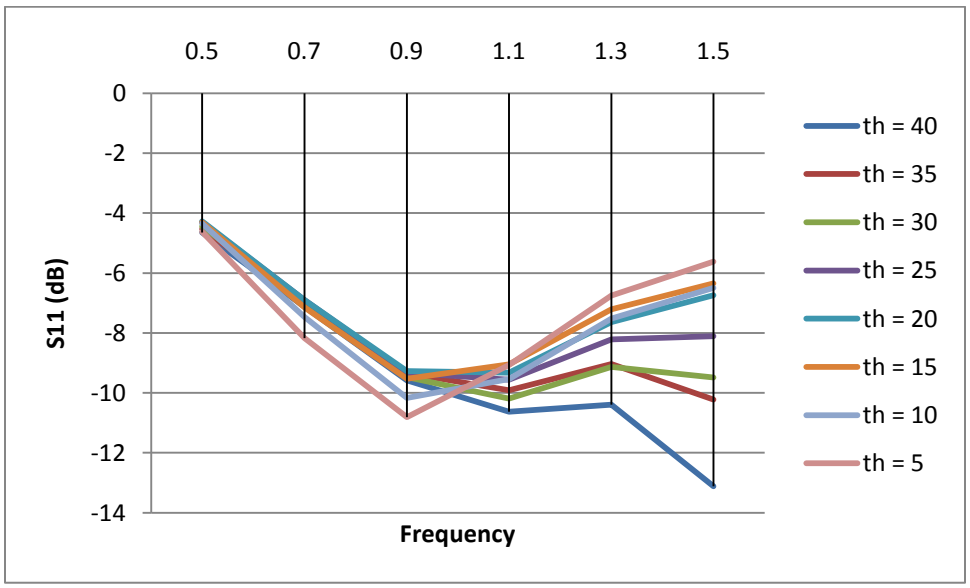

Fig. 3.3.3.7: low-frequency return-losses as a function of the "th" parameter

After choosing a particular angle of cut, the next step is to cut the substrate starting from the left edge. The parameter "o" indicates the number of millimeters that we will cut the substrate. For this simulation, we have determined that the angle "th" will be 30 degrees, as it is a good balance between return loss and space saving. Fig. 3.3.3.8 shows the response of the parameter "o", we can conclude that a nice cut value is 8mm.

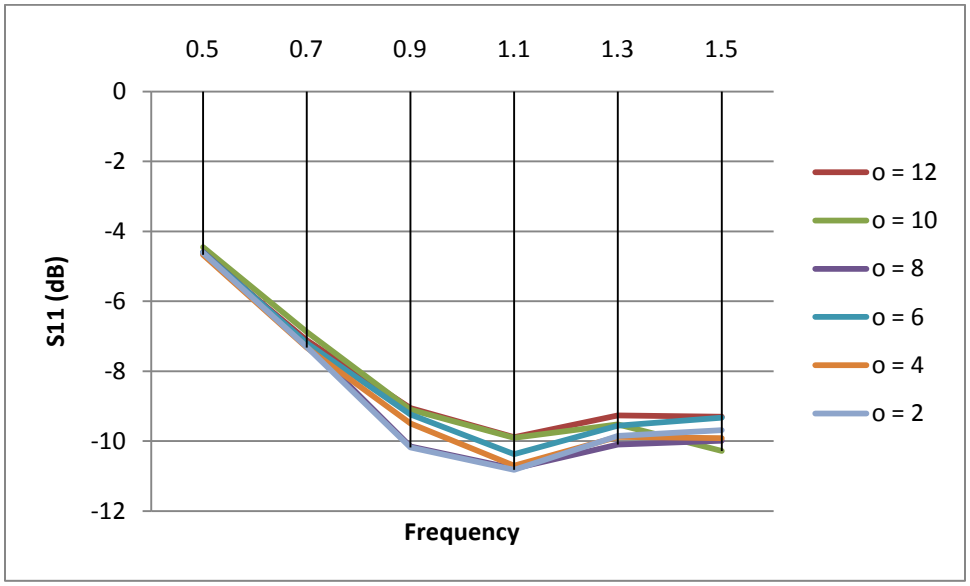

Fig. 3.3.3.8: low-frequency return-losses as a function of the “o” parameter

The next step is to try to improve the ground plane, for this issue we have tried the following (remember that until now, we have two edges, each one of 20mm at both sides of the antenna):

- Keeping the right edge (l = 20mm) and varying the value of the edge of the left (l1).
- Keeping the left edge (l1 = 20mm) and varying the value of the edge of the right (l).

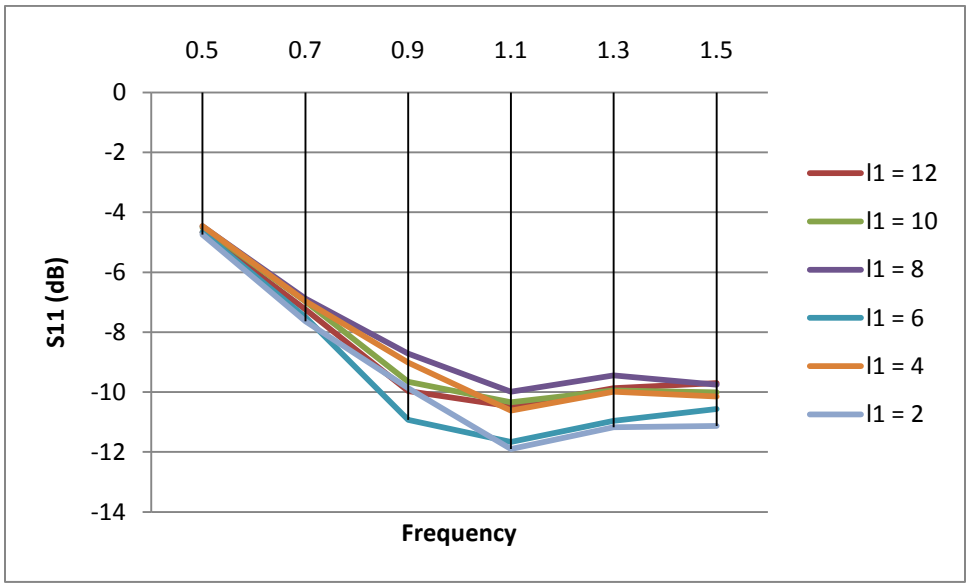

Fig. 3.3.3.9: low-frequency return-losses as a function of the "l1" parameter

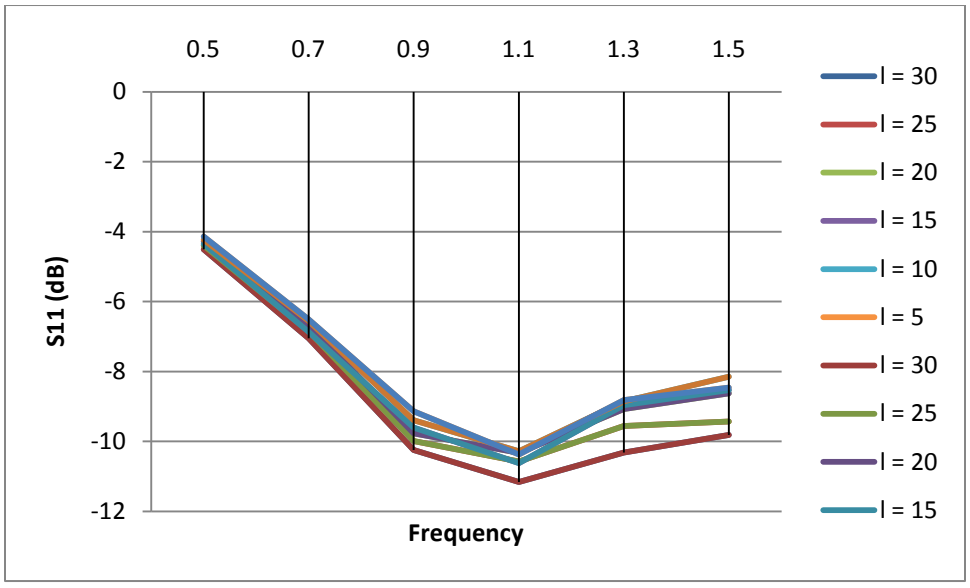

Fig. 3.3.3.10: low-frequency return-losses as a function of the "l" parameter

Because a variation of the left edge has provided better results, and moreover, a low value for the left side has shown a good performance (Fig. 3.3.3.9), we have decided to cancel the left edge and perform another simulation varying the right edge.

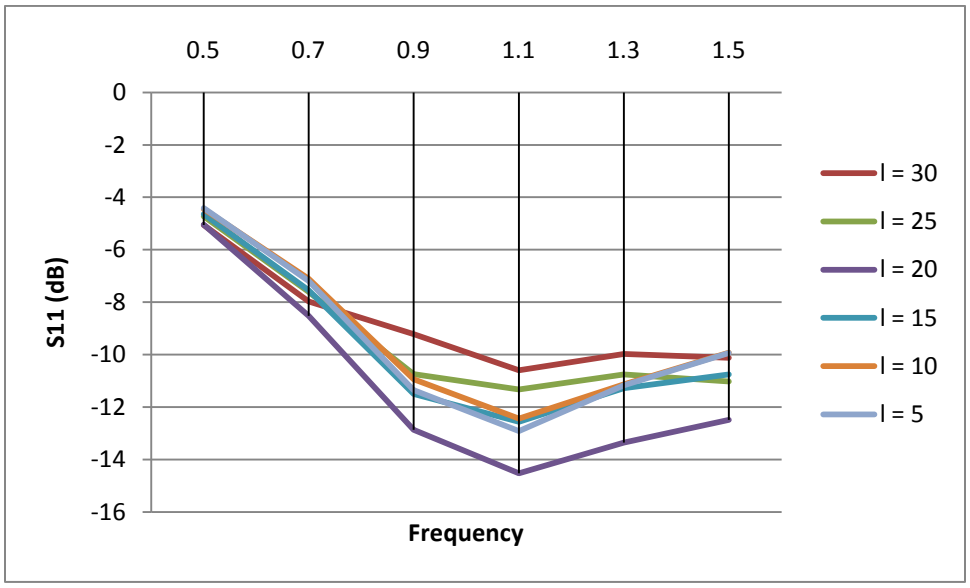

Fig. 3.3.3.11: low-frequency return-losses as a function of the "l" parameter

From Fig. 3.3.3.11 we can conclude that the best performance was obtained by removing the left edge and by maintaining the right edge with 20 mm side long.

3.3.4 Size-Improved Antenna

After having analyzed each of the previous settings and after making many simulations, we have concluded that the antenna to be manufactured would be the one shown in Fig. 3.3.4.1. We had to make a consideration with the angle of cut, as the most optimum was "th = 40", but because with this value the overall size of the antenna was almost the same, a compromise between S11 and dimension is made, so we choose the 30 degree angle.

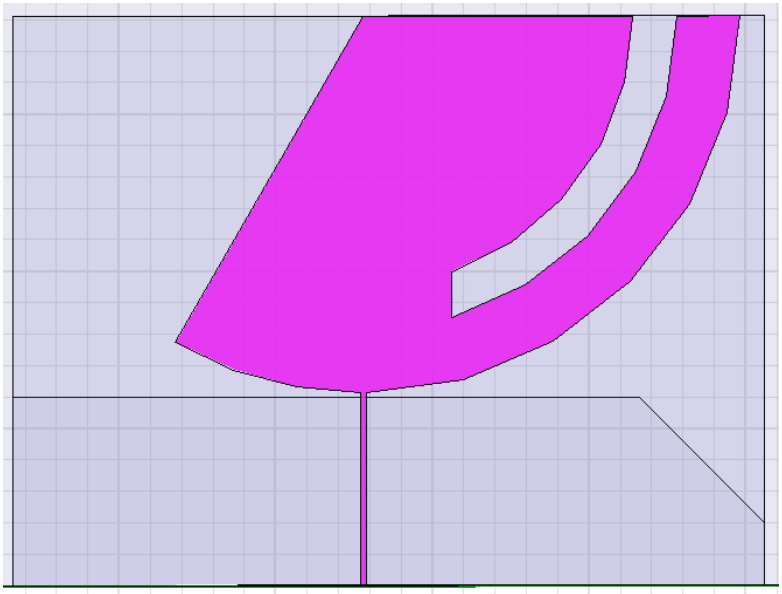

Fig. 3.3.4.1: Size-Improved antenna.

Table 3.3.2.1: Final values for the 2D base-antenna, the name of the values are taken from Fig. 3.3.3.1 and Fig. 3.3.3.6

Name	Value
L	90.6 mm
W	120 mm
l	20 mm
gr	30 mm
g	0.6 mm
r	60 mm
dd	14 mm
dr	10mm
dw	7mm
th	30 degrees
o	8mm

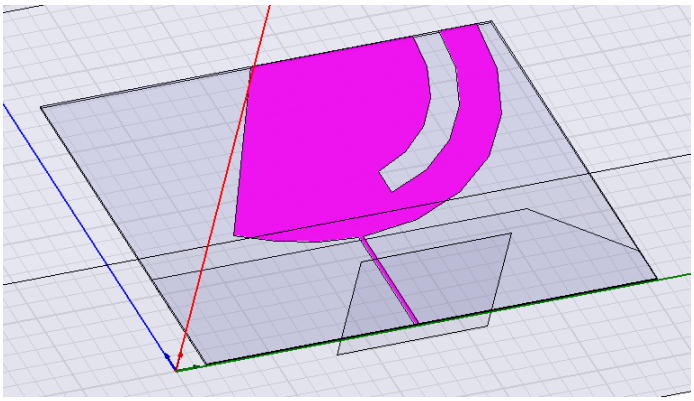

Fig. 3.3.4.2: 3D view of the size-improved antenna (HFSS11)

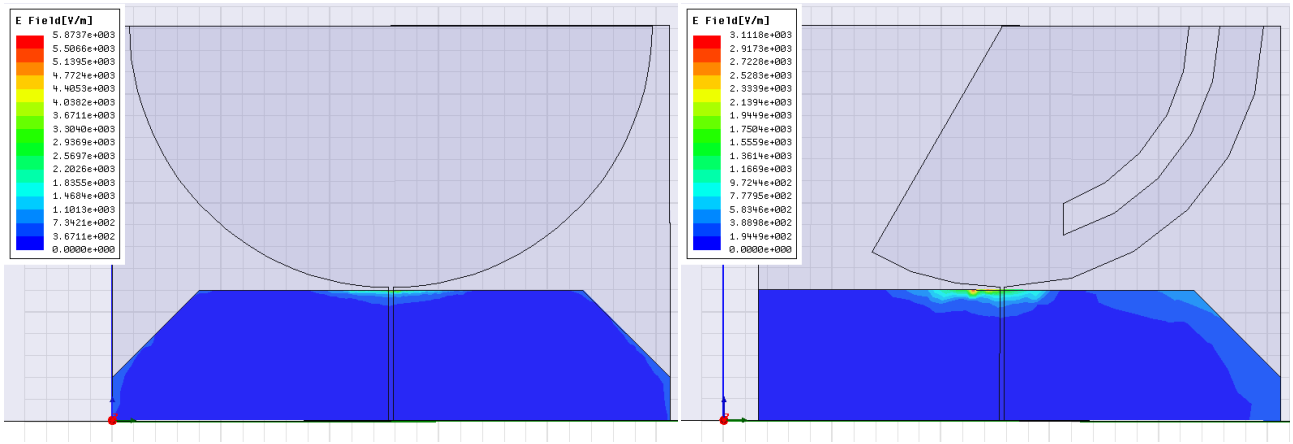
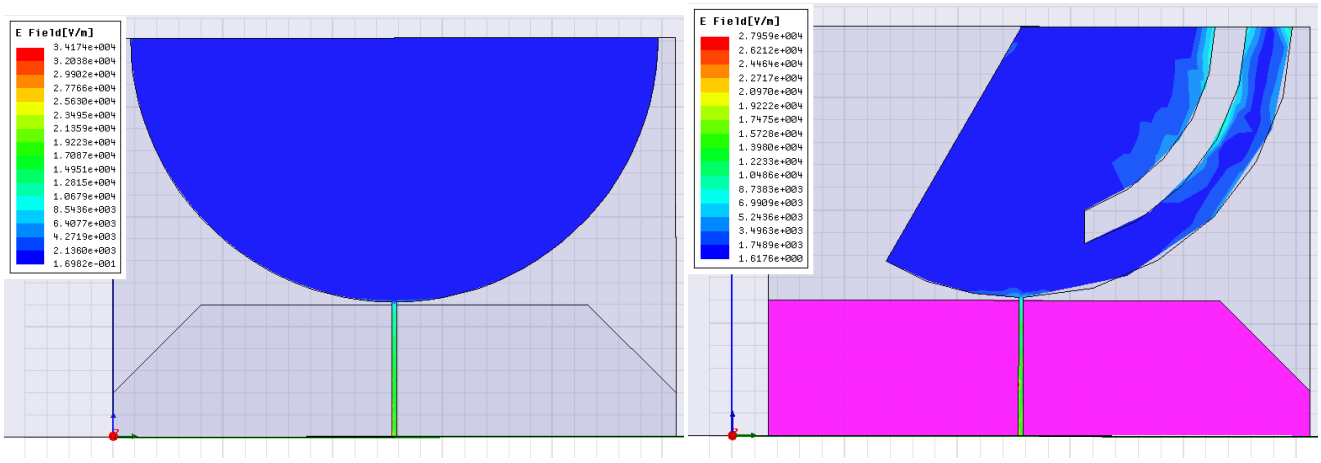
As explained above, now that we have decided on our new size-improved antenna values, the current distribution between the antennas are not the same. In the following figures we will appreciate that, as for the radiating patch and for the ground plane as well, the current distributions have changed. The differences for each frequency could also be seen clearly.

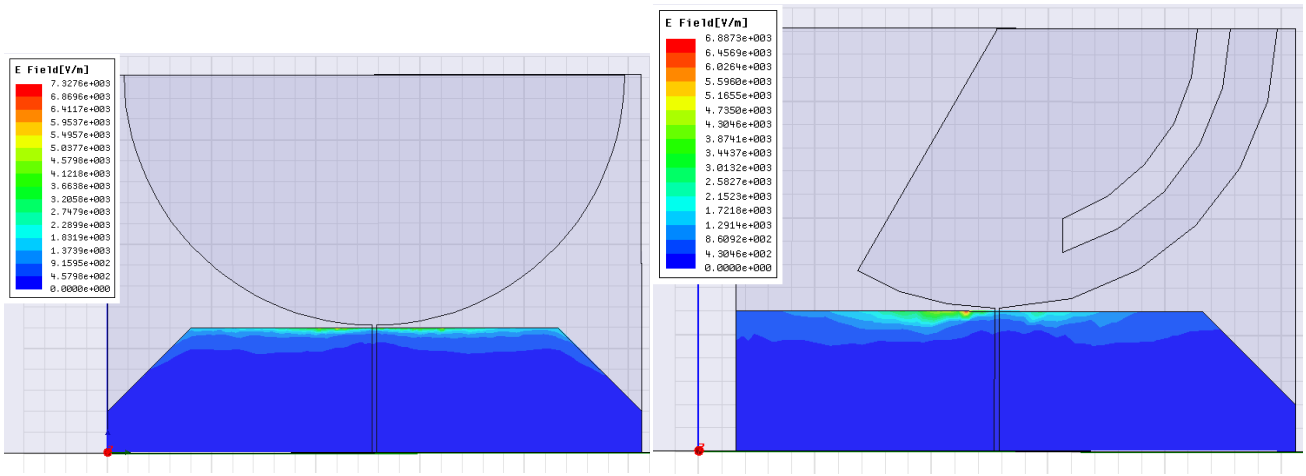


(a)



(b)

Fig. 3.3.4.3: Current distributions for (a) ground plane and (b) radiating patch at 900 MHz



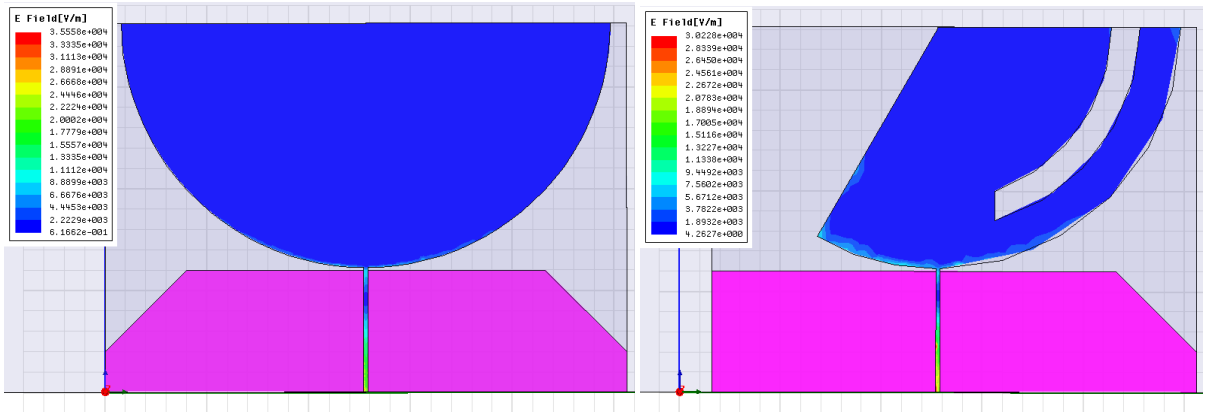


Fig. 3.3.4.4: Current distributions for (a) ground plane and (b) radiating patch at 1.85 GHz

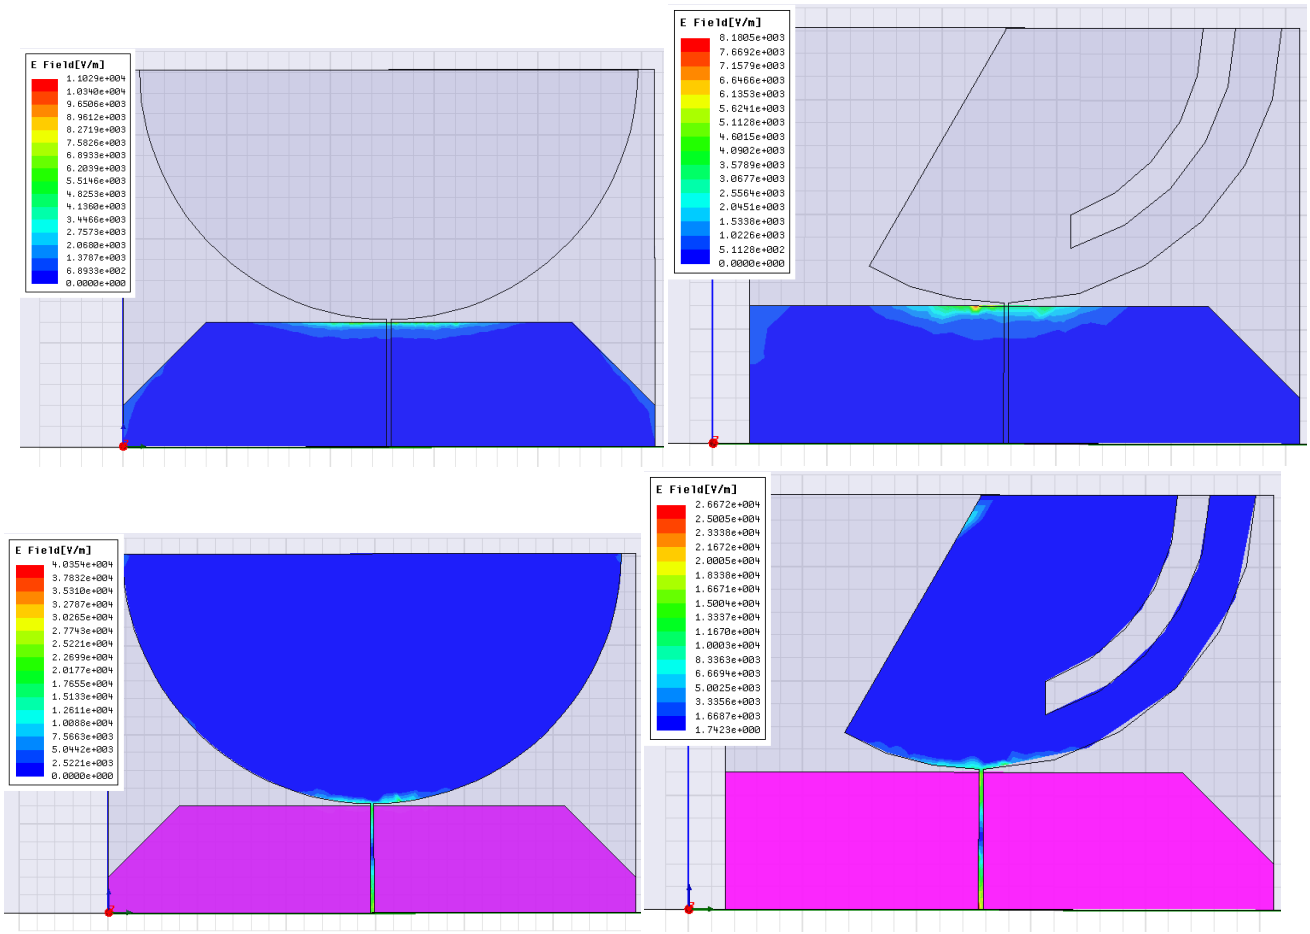

Fig. 3.3.4.5: Current distributions for (a) ground plane and (b) radiating patch at 2.45 GHz

We can see that for low frequencies, most of the current is concentrated around the right side of the antenna, where the slot is located. And we also can observe that the current on the left side of the antenna is very weak. The graphs also suggest that this behavior (current distribution) affects lower frequencies more than higher frequencies. For higher frequencies, we see that the current is distributed in the feed line and the base of the antenna.

Some of the drawbacks of applying these techniques miniaturization are that the result, as in our case, turns out to be asymmetrical. The feed lines, as well as the notch in the ground plane are no longer symmetrical. Direct consequence of this asymmetrical physical change is the radiation pattern.

3.4 Antenna Fabrication and measurements

3.4.1 Fabrication

For the manufacture of the antennas, a LPKF Protomat C100 HF Milling machine (Fig. 3.4.1.1) was used. This machine has a set of drills to fit the milling desired size (Fig. 3.4.1.2). First we exported the antenna design file from the HFSS11 software to the software used by the machine. This machine cuts the metal layer of the used substrate (A25N) so that we "draw" the antenna shape (Fig 3.4.4.2). After having the shape of the antenna, we have to turn the substrate to repeat the same procedure to "draw" the ground shape. After it, all the substrate is separated from the entire substrate plate by making a deeper cut. Then, using a hand cutter, we remove the exceeding copper layers (Fig. 3.4.1.4) that are not part of our antenna design. Finally, we have to solder a 3.5mm SMA female connector on the fed line.

Fig 3.4.1.1: Milling machine

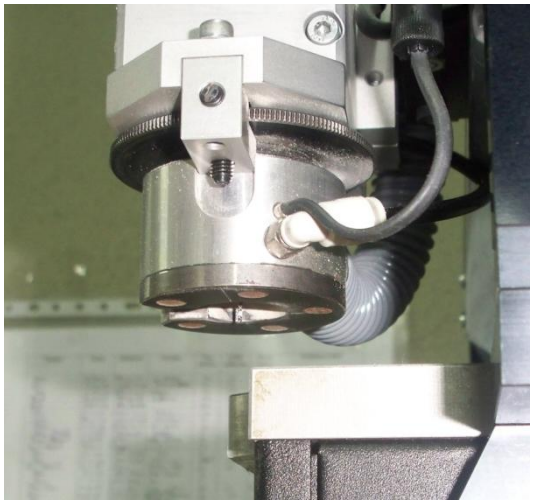

Fig 3.4.1.2: Cutting Drill

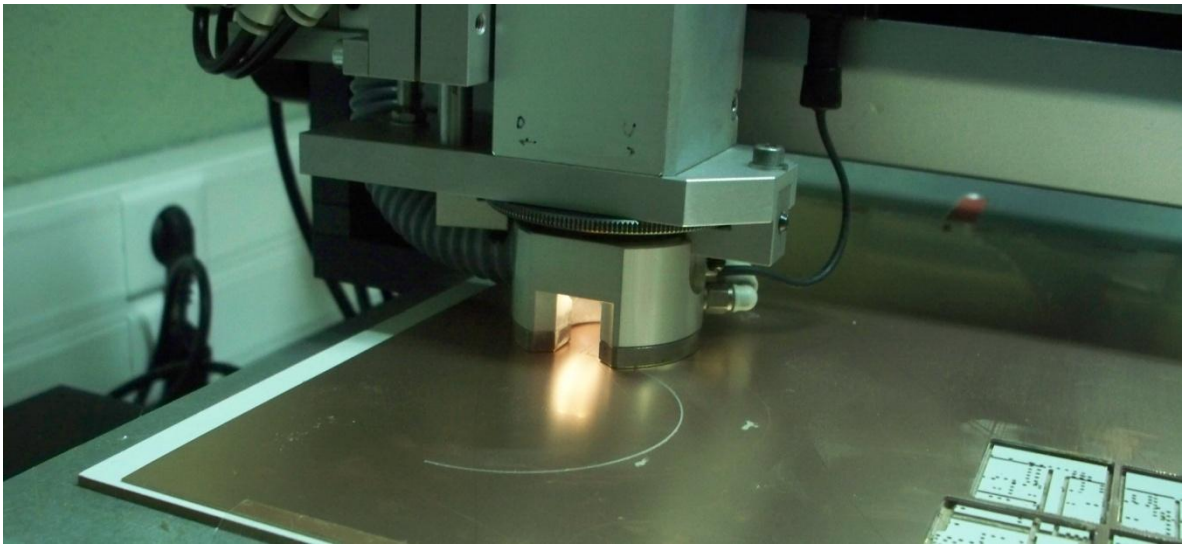

Fig 3.4.1.3: Milling machine shaping our antenna

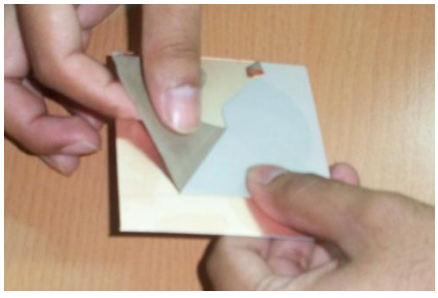

Fig 3.4.1.4: Exceeding Cupper

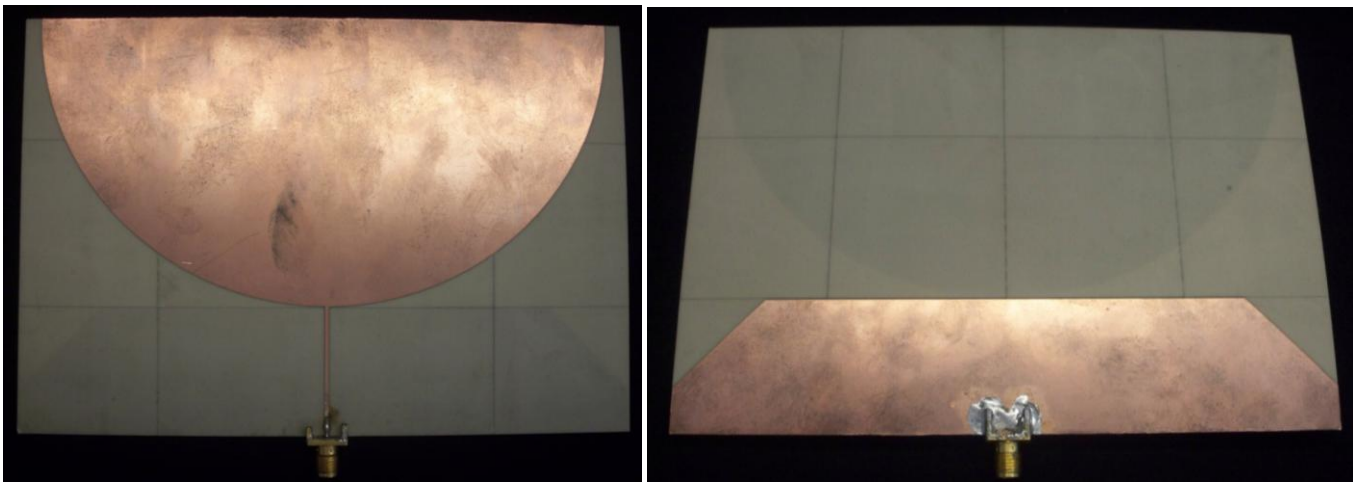

Fig. 3.4.1.5: base-antenna front and back view

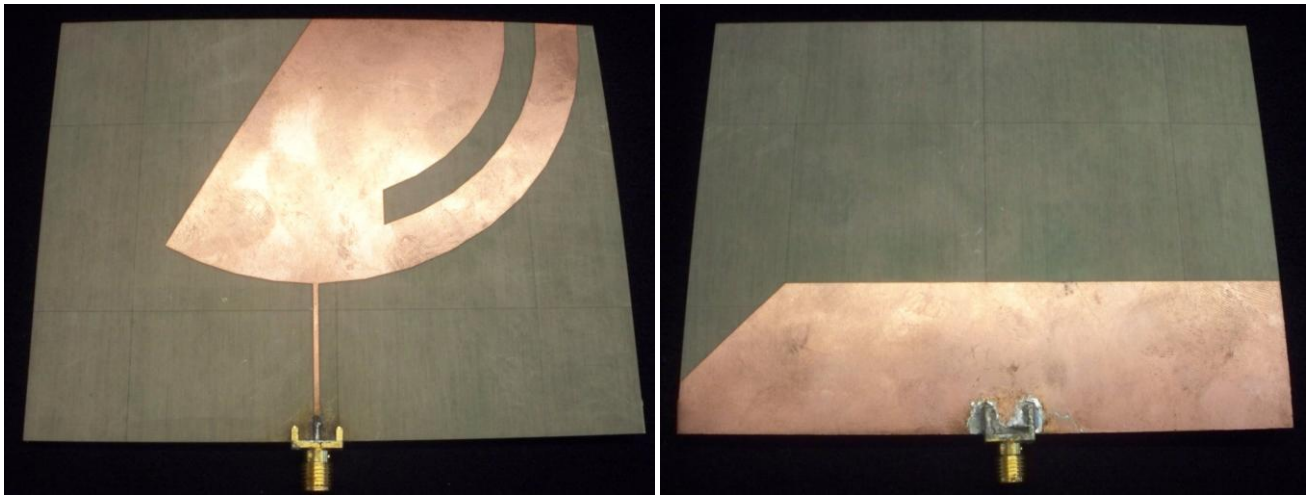

Fig. 3.4.1.5 size-improved antenna front and back view

3.4.2 Measurements

For measurements of the antennas was used a ZVA24 Rohde & Schwarz Vector Network Analyzer (VNA). Since we want to know the energy that our antenna "bounces" and these frequencies, then we have to measure the S11 parameter. A deeper explanation of the parameters S in section 4.3.1 will be done.

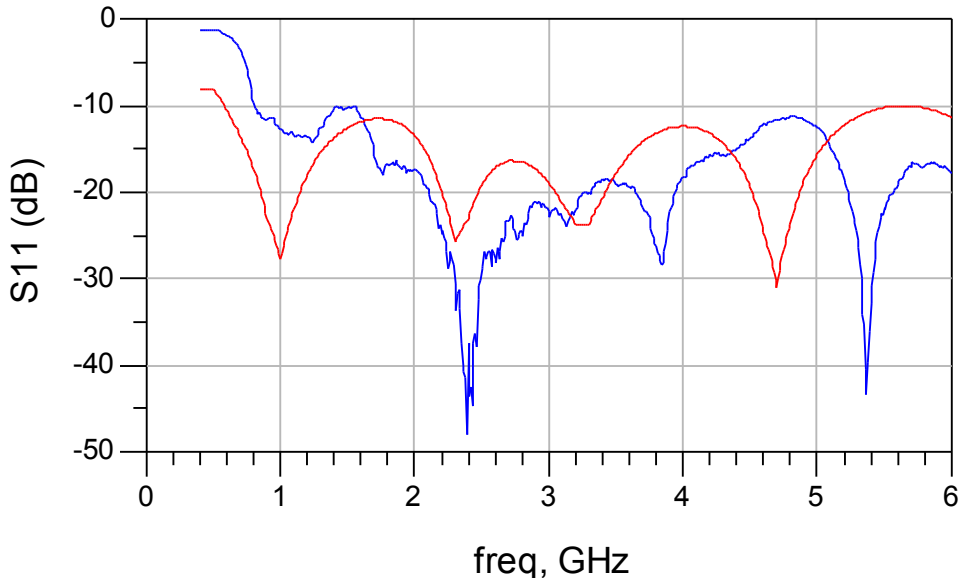

Fig. 3.4.2.1: S11 parameters measured for the base antenna in red compared with the simulated results in blue.

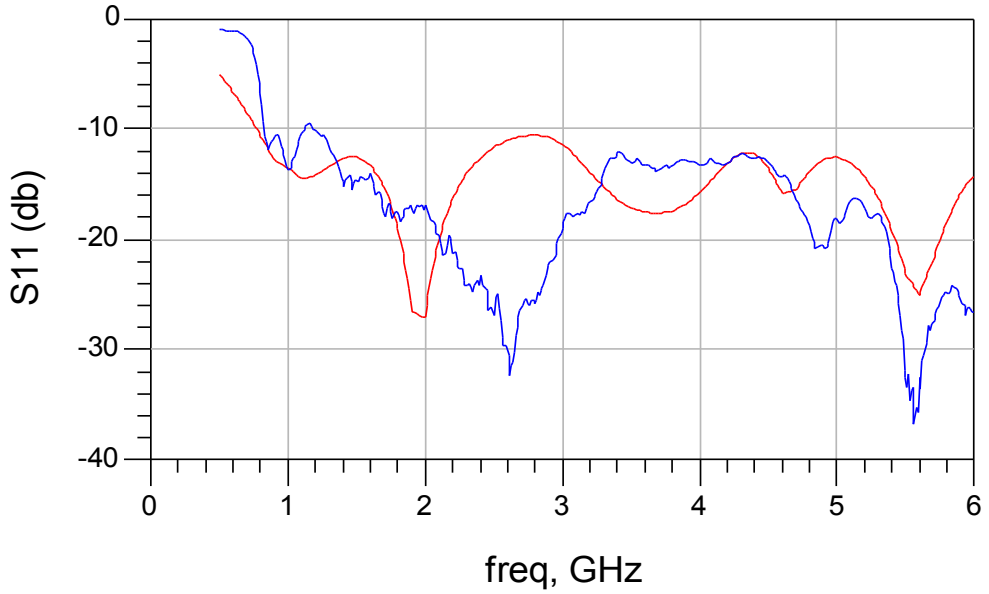

Fig. 3.4.2.2: S11 parameters measured for the size-improved antenna in red compared with the simulated results in blue.

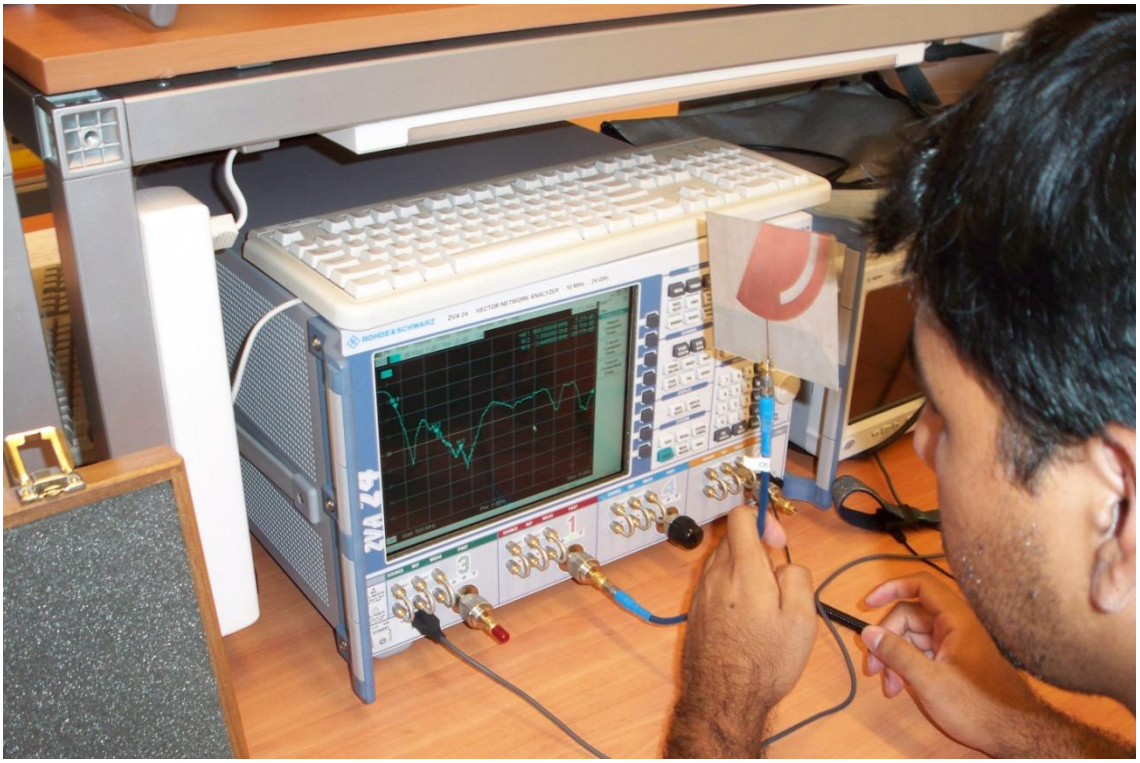

Fig. 3.4.2.3 Vector Network Analyzer, making some measurements.

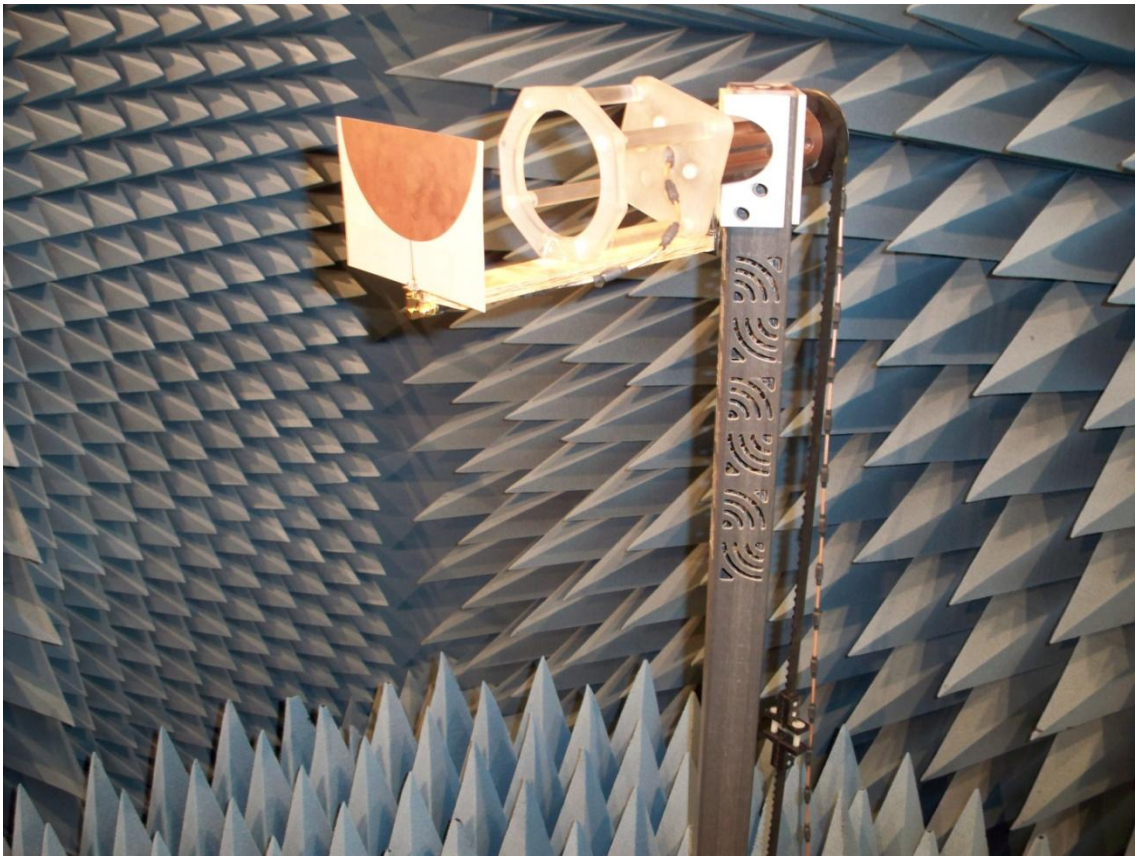

Fig. 3.4.2.4: Anechoic Chamber.

Fig. 3.4.2.1 and Fig. 3.4.2.2 compare the VNA measurements with th software simulations. We can conclude that there is a good correspondence between the measurements and simulations.

Measurements in the anechoic chamber are used for far field antenna characteristics. In Figs. 3.4.2.5 – 3.4.2.8, that show the radiation patterns, rETheta (φ = 0) and rEPhi (φ = 90), are cross-polarization measurements and rETheta (φ = 90) and rEPhi (φ = 0), represent co-polarization measurements. It can be seen that in Figure 3.4.2.5 and 3.4.2.6, which are measurements of the base antenna; there is a marked polarization in the cross-polar direction, and in Fig. 3.4.2.7 and Fig. 3.4.2.8 (Size-improved antenna), theoretically with similar behavior than the first antenna, the measurements show some response in the cross-polar direction.

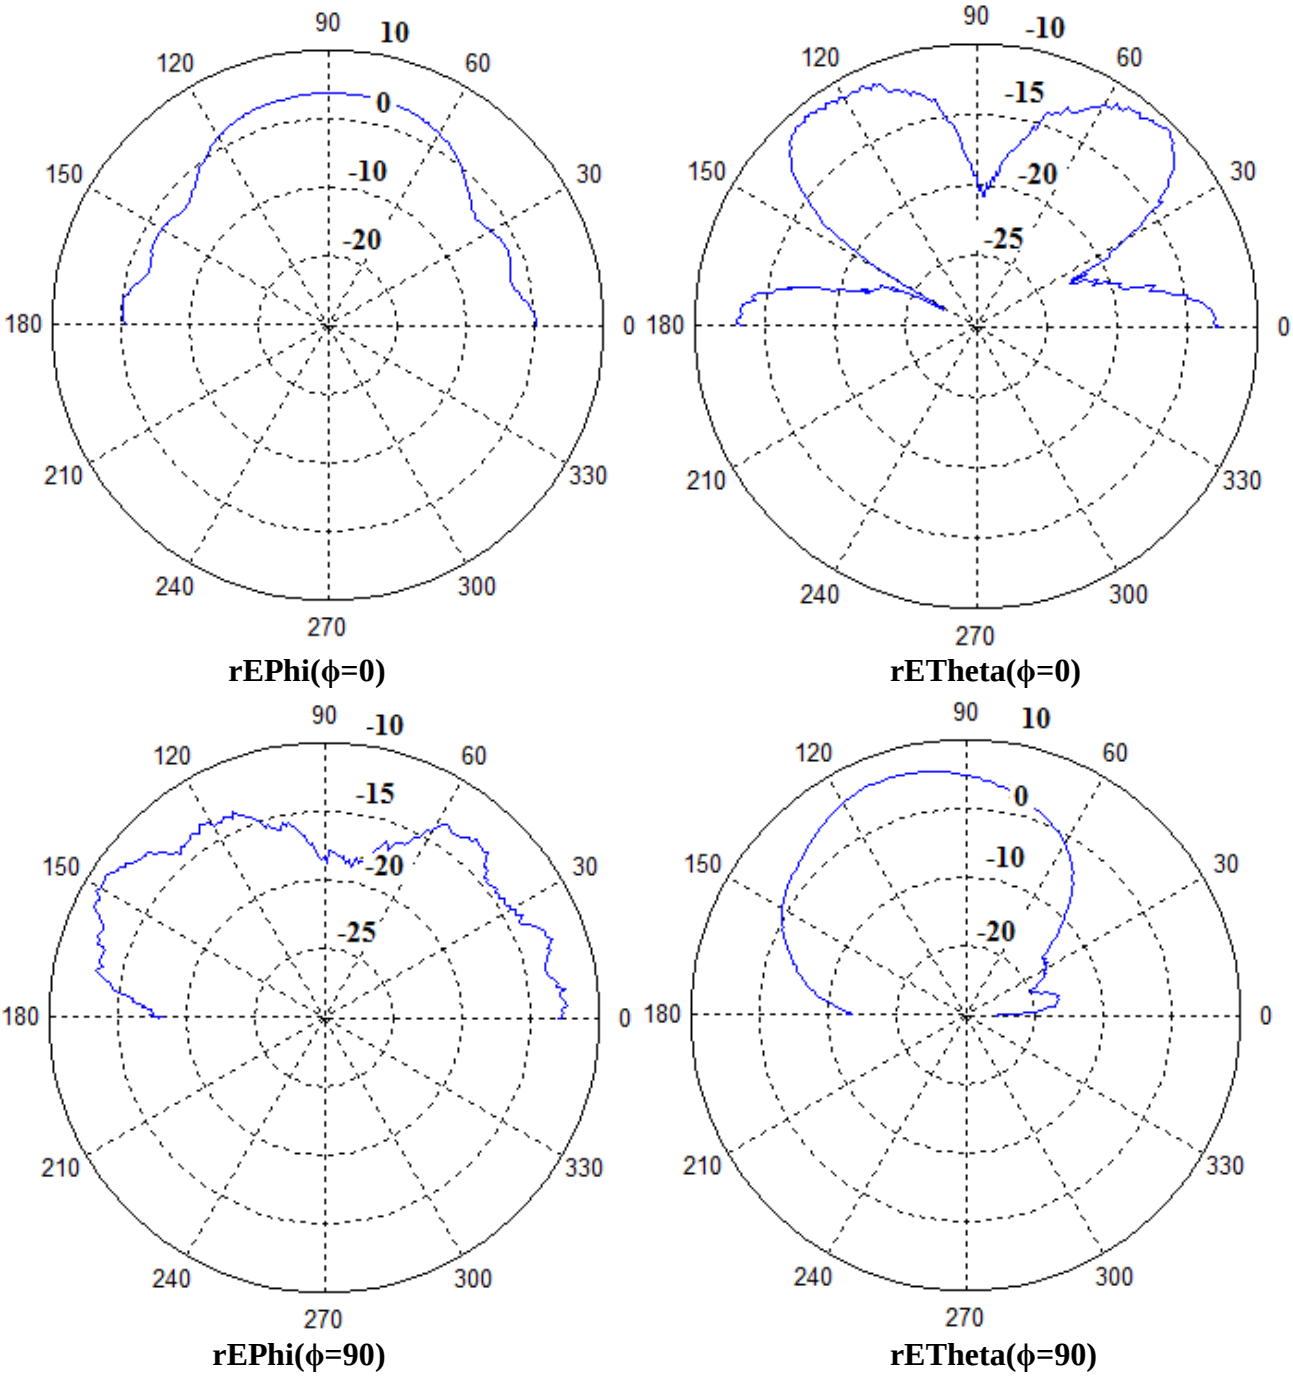

Fig. 3.4.2.5 measured radiations patterns at 1.85 GHz for the base-antenna.

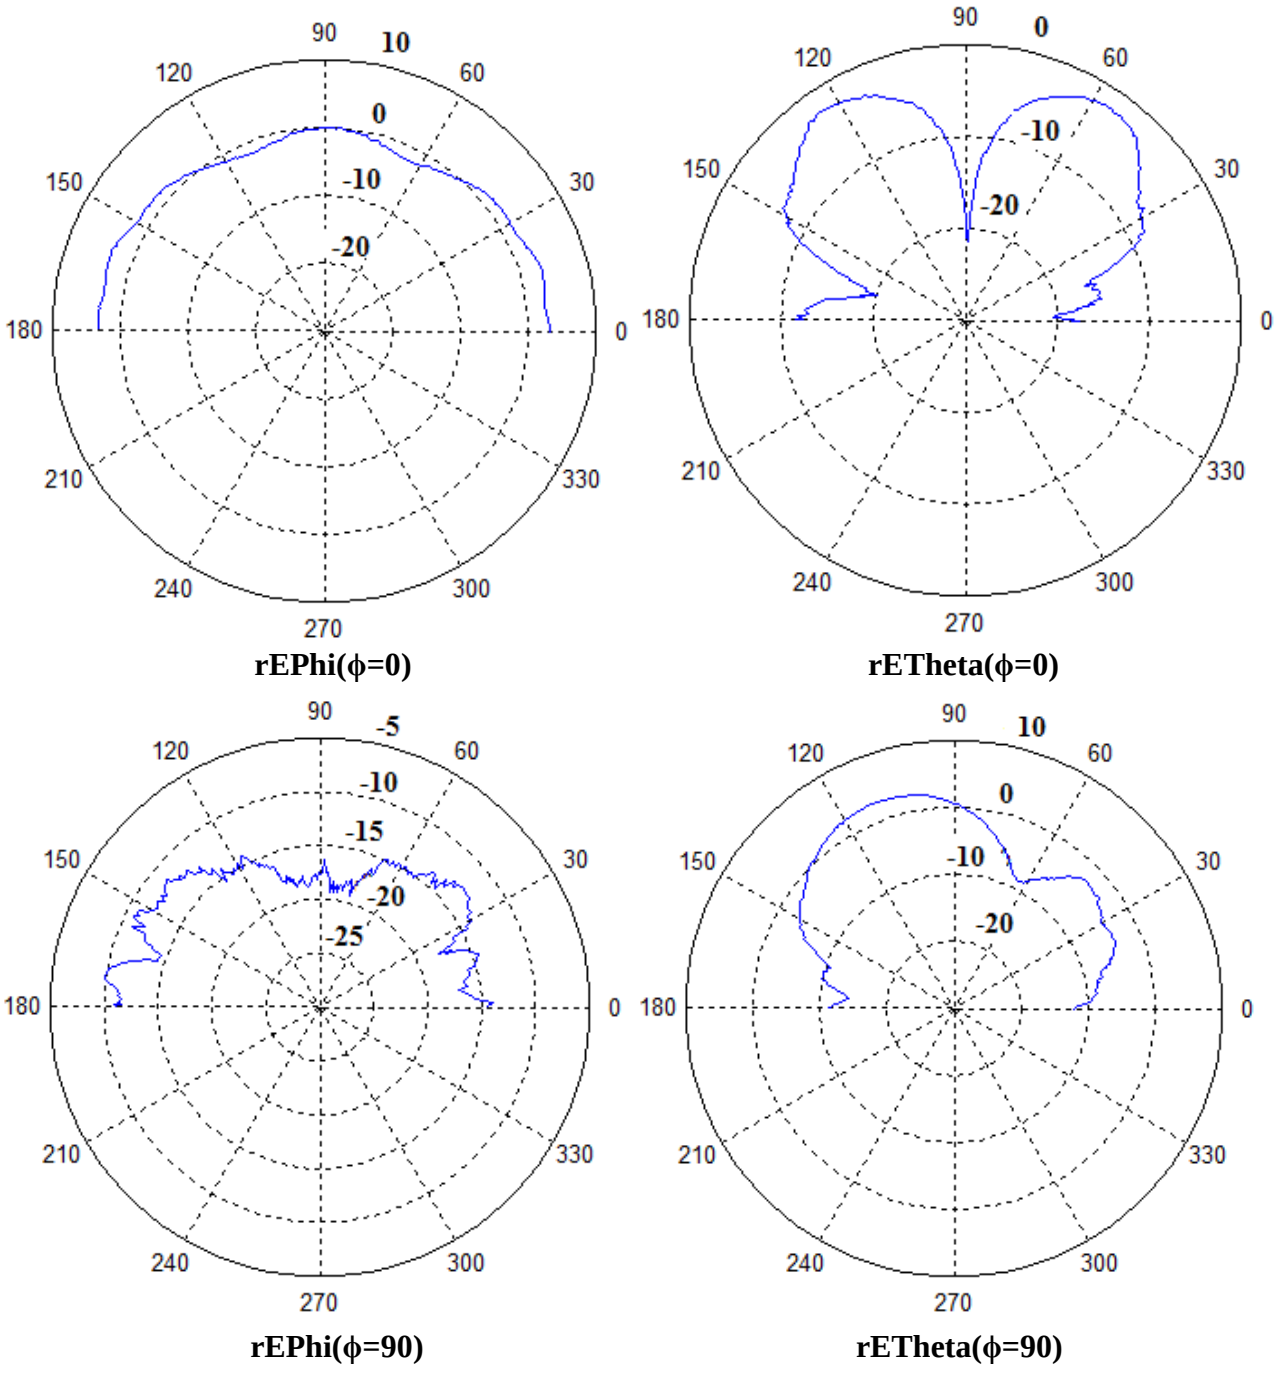

Fig. 3.4.2.6 measured radiations patterns at 2.45 GHz for the base-antenna.

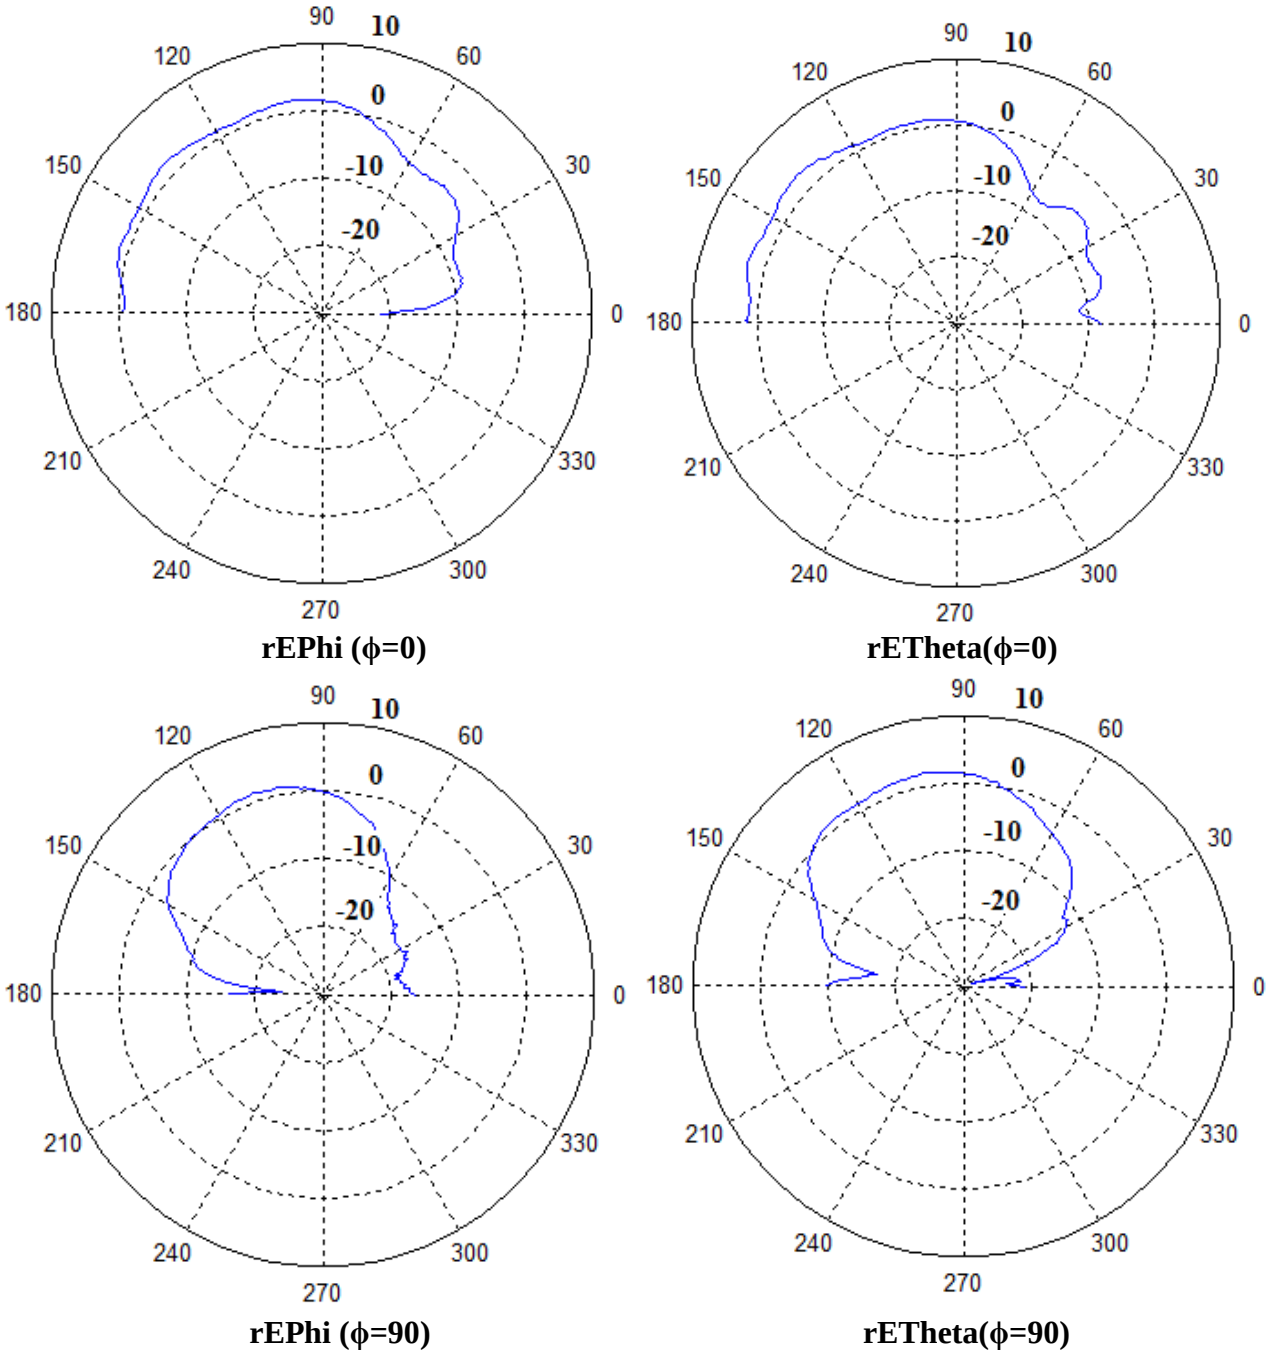

Fig. 3.4.2.2 measured radiations patterns at 1.85 GHz for the size-improved antenna.

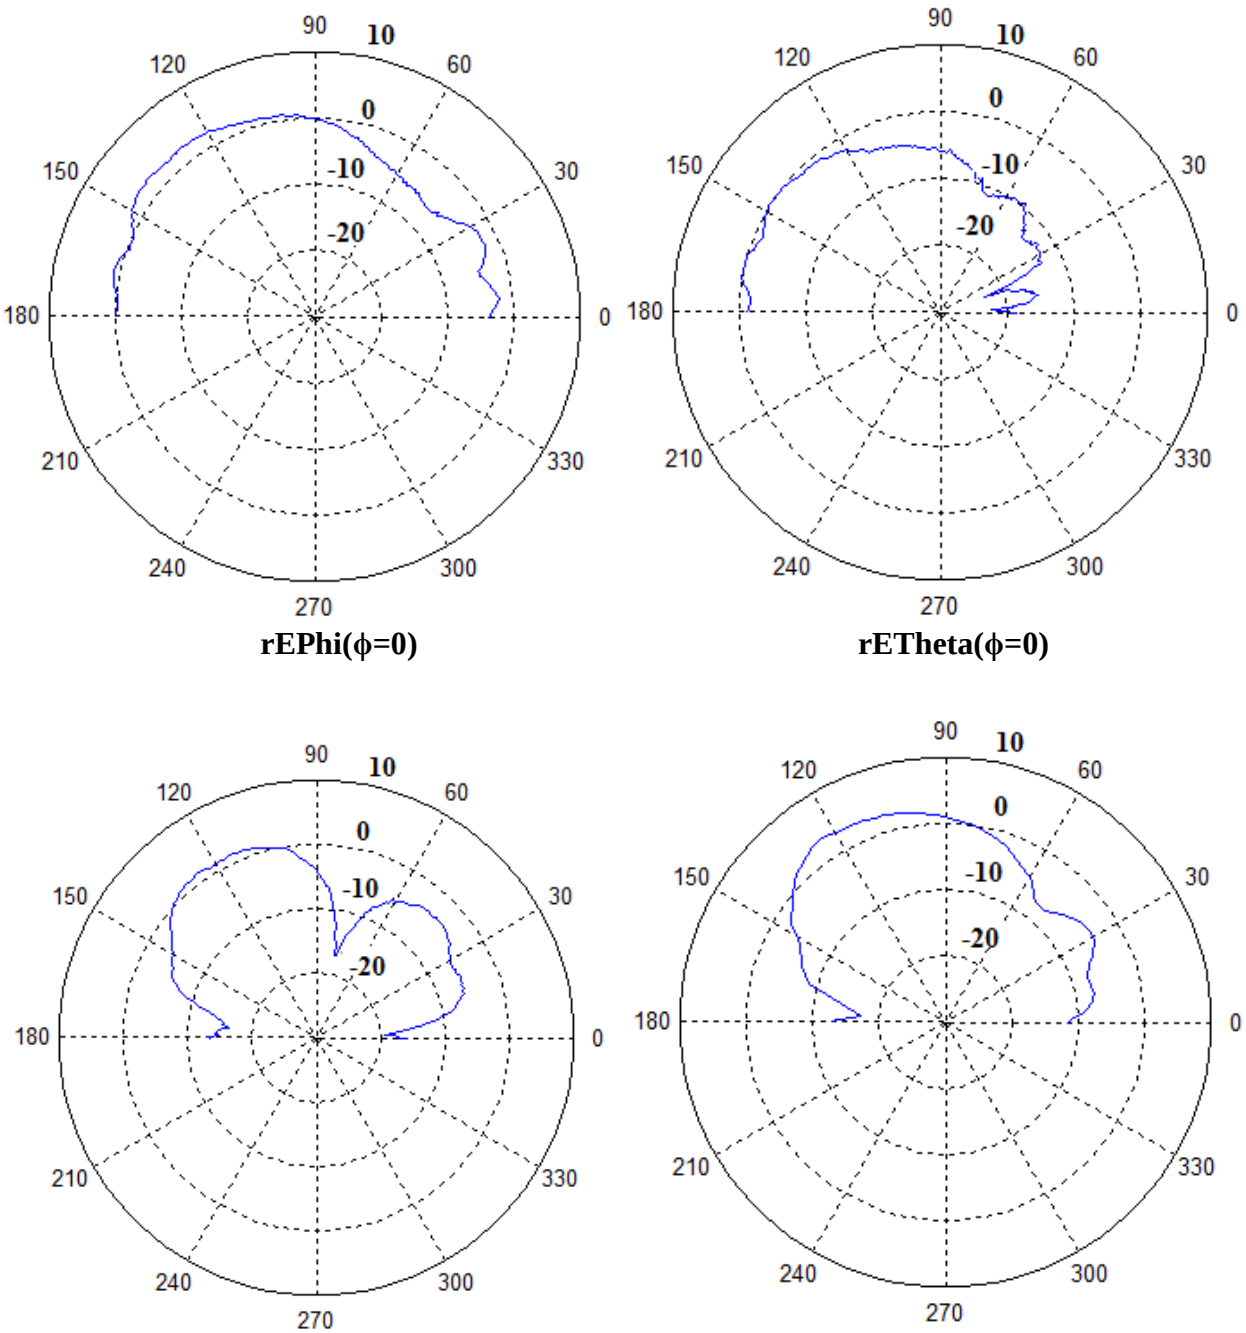

Fig. 3.4.2.8 measured radiations patterns at 2.44 GHz for the size-improved antenna.

Chapter 4

Rectifier Design

4.1 Rectifier

A rectifier is an electrical device that converts alternating current (AC), which periodically reverses direction, to direct current (DC), current that flows in only one direction, in a process known as rectification. Rectifiers have many uses including as components of power supplies and as detectors of radio signals.

There are two types of rectifier, the half wave and full wave. Each type can either be uncontrolled, half-controlled or fully controlled. An uncontrolled rectifier uses diodes, while a full-controlled rectifier uses thyristor or popularly known as Silicon Controlled Rectifier (SCR). A half controlled is a mix of diodes and thyristors. The thyristors need to be turned on using a special triggering circuit. In our application, given the ease of matching because of the fewer number of components, has been used a half-wave rectifier.

4.1.1 Commutating Diode

Mostly, for half or uncontrolled circuit they include also a diode across the load as shown in Fig. 4.1.3.1 This diode is variously described as a freewheeling diode (FWD), flywheel or bypass diode, but is best described as a commutating diode as its function is to commutate or transfer load current away from the rectifier whenever the load current away from the rectifier whenever the load voltage goes into a reverse state.

4.1.2 Schottky diode

The Schottky diode is a semiconductor diode with a low forward voltage drop and a very fast switching action. A Schottky diode is a special kind of diode with a very low forward-voltage drop. When current flows through a diode there is a small voltage drop across the diode terminals. A normal silicon diode has between 0.6–1.7 volt drops, while a Schottky diode voltage drop is between approximately 0.15–0.45 volts. This lower voltage drop can provide higher switching speed and better system efficiency. For our rectifier, we have used a SKYWORKS® Schottky diode (Fig. 4.1.2).

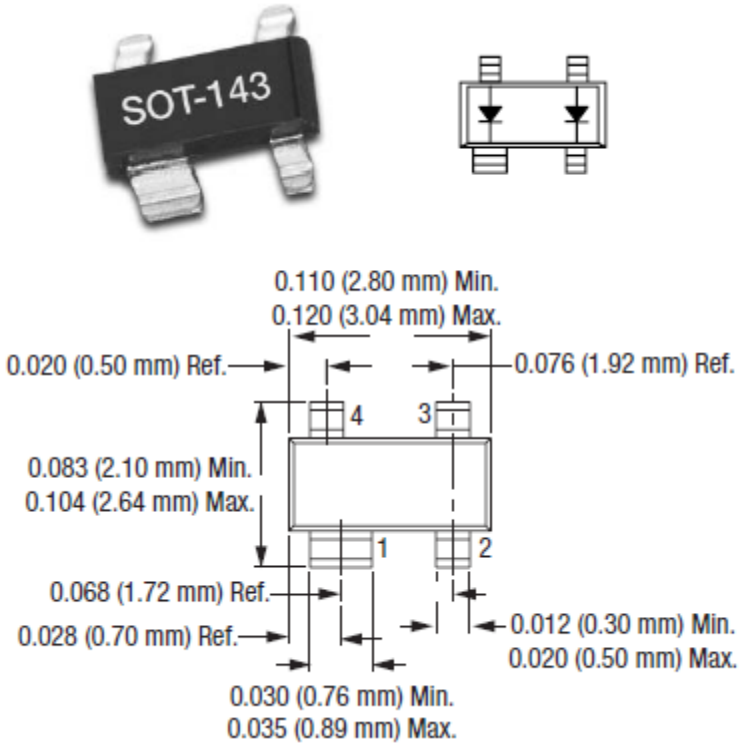

Fig. 4.1.2 SKYWORKS Schottky diode picture, pins and dimensions

4.1.3 Half-Wave Rectifier

In practice, the half-wave rectifier is used most often in low-power applications because the average current in the supply will not be zero. This may cause problems in transformer performance.

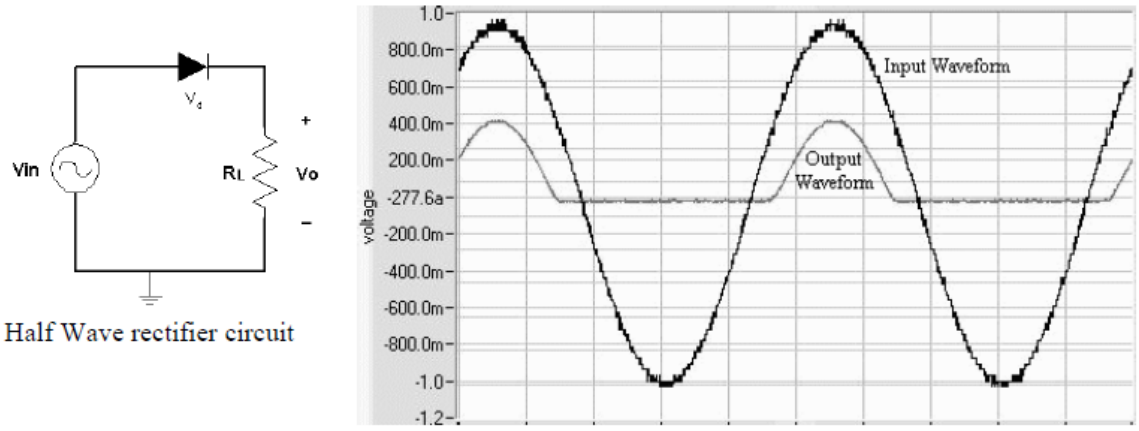

Fig. 4.1.3.1 Half wave rectifier input and output wave example

When a capacitor is connected in parallel with RL, the half wave output becomes a "filtered" DC. As the voltage of the input sine wave increases, the diode will begin to conduct and charge the capacitor. When the input sine wave voltage falls below the capacitor voltage, the diode turns off and the capacitor discharges into the load.

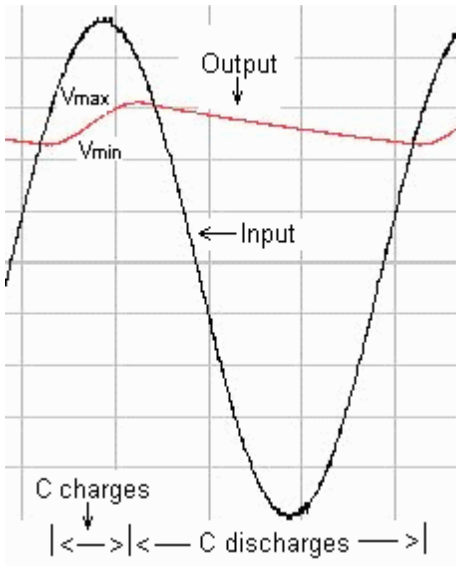

Fig. 4.1.3.2: Operation of the rectifier when placing a capacitor in parallel with RL

The size of the resistor will determine Vmin. As the load resistance is increased: IL decreases, the capacitor discharges less, Vmin increases, Vrms (effective voltage) increases, and Vpp (ripple voltage) decreases. Vmax does not change much because the diode forward voltage drop is relatively constant and Vmax = Vin – Vd.

4.2 RF to DC efficiency

At some applications explained in chapter two and others like the reception of a microwave beam sent to the earth by a geostationary solar power satellite, distributed DC powering of actuator, or DC supplying of RFID passive tags, the RF to DC conversion efficiency is the parameter to improve over the range of incident power or output voltage of interest. Different solutions have been reported, mainly based on combining dipole or patch printed elements with diode detectors. The RF-DC conversion efficiency of the rectenna with a diode depends on the microwave power input intensity and the connected load. We need to get the optimum microwave power input intensity and the optimum load to achieve maximum efficiency. When the power or load is not well matched, the transferred power is not the optimal and the efficiency becomes quite low. The efficiency is also determined by the characteristic of the diode; the diode has its own junction voltage and breakdown voltage. If the input voltage to the diode is lower than the junction voltage or is higher than the breakdown voltage, the diode does not show a rectifying characteristic. As a result, the RF-DC conversion efficiency drops with a lower or higher input than the optimum.

The average RF power over a range of frequencies at any instant in time is given by:

$$\left(\frac{1}{f_h - f_l}\right)\int_{f_l}^{f_h}\int_{0}^{4\pi} S(\theta,\phi,f,t)A_{eff}(d\Omega df)$$

The DC power for a single frequency (fi) input RF power is given by:

$$P_{DC}(f_i) = P_{RF}(f_i,t)\eta[P_{RF}F(f_i,t),\rho,Z_{DC}]$$

where η is the conversion efficiency:

$$\eta[P_{RF}F(f_i,t),\rho,Z_{DC}] = \frac{P_{DC}(f_i)}{P_{RF}(f_i,t)}$$

4.3 Rectifier Simulation Tools

For rectifier simulations and also each of its components, we have used the Agilent ADS2008 software. In this section we describe some of the modules and tools used, and a brief explanation of its operation is also made.

4.3.1 S-parameter analysis.

The objective of microwave circuit analysis is to move from the requirement to solve all the fields and waves of a structure, to an equivalent circuit that is amenable to all the tools of the circuit analysis. However, the tools that are appropriate for lumped circuits must be extended to apply to distributed networks.

A matrix that is of great use in microwave network problems is the "scattering" matrix, so-called by analogy to the scattering or reflection of waves by a free-space reflector. S-parameters have become the preferred description of microwave n-ports for the following reasons:

- Voltage and current are difficult to define and measure in distributed circuits
- Incident and reflected waves are the natural description for microwave structures
- Conversion from S-parameters to other parameter sets is a matter of routine algebra
- S-parameters benefit from the matrix operations.

S-parameter simulation is a type of small-signal AC simulation. It is most commonly used to characterize a passive RF component and establish the small-signal characteristics of a device.

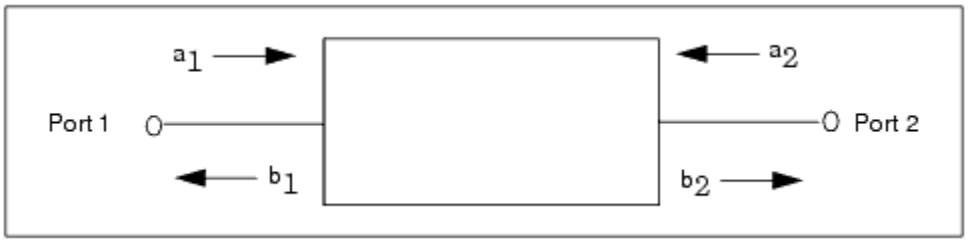

Fig. 4.3.1.1: Representation of a signal wave in a two-port electrical-element.

Fig. 4.3.1.1 shows a representation of a signal wave in a two-port electrical-element where:

- *a1* is the wave into port 1
- *b1* is the wave out of port 1
- *a2* is the wave into port 2
- *b2* is the wave out of port 2

The S-parameters for this conventional element are:

- $b1 = a1.S11 + a2.S12$
- $b2 = a1.S21 + a2.S22$

where:

- S11 is the port-1 reflection coefficient: S11= *b1/a1* when *a2*= 0
- S22 is the port-2 reflection coefficient: S22=*b2/a2* when *a1*= 0
- S21 is the forward transmission coefficient: S21= *b2/a1* when *a2*= 0
- S12 is the reverse transmission coefficient: S12= *b1/a2* when *a1*= 0

These equations can be solved for *b1* and *a1* in terms of *a2* and *b2* to yield the transmission T-parameters as follows:

- *b1*= *a2*.T11+ *b2*.T12
- *a1*= *a2*.T21+ *b2*.T22

Fig. 4.3.1.2 shows the T-Parameters matrix.

$$\begin{bmatrix} t_{11} & t_{12} \\ t_{21} & t_{22} \end{bmatrix} = \begin{bmatrix} s_{12} - s_{11} & s_{22}/s_{21} \\ -s_{22}/s_{21} & 1/s_{21} \end{bmatrix} \quad s_{11}/s_{21}$$

Fig. 4.3.1.2: relationship between the T-parameters and the S-parameters

S-parameters are defined with respect to reference impedance that is typically 50 ohms. For 50-ohm S-parameters-with the 2-port element terminated with 50 ohms at each port, the s21 parameter represents the voltage gain of the element from port 1 to port 2.

4.3.2 Harmonic Balance

Harmonic balance is a method to analyze the distortion in non-linear circuits or systems. This method is usually applied when we need to simulate RF or microwave problems since these are most naturally handled in the frequency domain.

Source voltage and current of a circuit can generate discrete frequencies by generating a discrete frequency spectrum at different points in the system. Linear components of a circuit are modeled in the frequency domain while non-linear components are modeled first in the time domain and then Fourier-transformed in the frequency domain before each solving step.

This method first divides the circuit into two groups, the linear elements, where are also included input impedances of the sources, and the group of non-linear elements. Fig. 4.3.2 shows a schematic of these two groups.

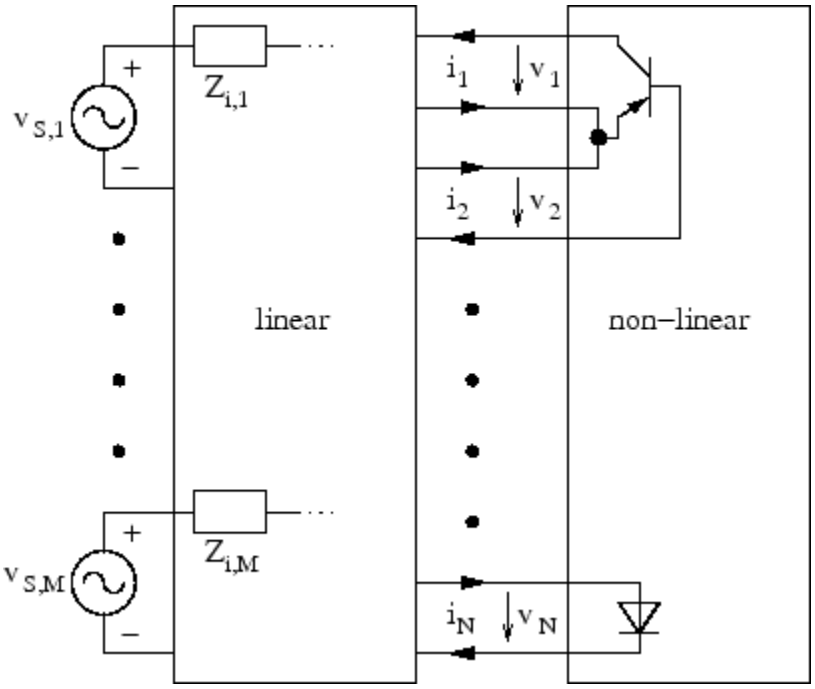

Fig. 4.3.2 Schematic of Harmonic Balance component division [20]

It is considered that a solution has occurred when the current between the groups is the same for the linear elements and for the non-linear. That is why the method is called harmonic balance, because the current between the two groups must be balanced for each harmonic frequency. It is also possible to know all the voltages at each of the interconnections between the two groups, once known these values of balanced voltages and currents, it performs a classic AC analysis and we can know the voltage and current value at any point of the circuit.

In our application we have used this method because the circuit has only one non-linear element that is the diode, moreover, the circuits that we have simulated does not require much computer processing, which makes the simulation faster.

4.3.3 ADS2008 Matching Utility

Since our application consists basically of an antenna and a rectifier circuit, is required an impedance matching to ensure good power transfer and performance. The ADS2008 impedance matching utility is a software tool that allows us to place a component in our scheme and, according to certain parameters manually defined, generate a matching circuit which can then be optimized according to our goals.

Fig. 4.3.3.1 shows an example of how the impedance matching component is placed in the circuit scheme. For our application we chose a band-pass matching circuit, that was

subsequently optimized for best performance in our application bands, because matching a network over a broad band is complex and it will require a larger amount of components.

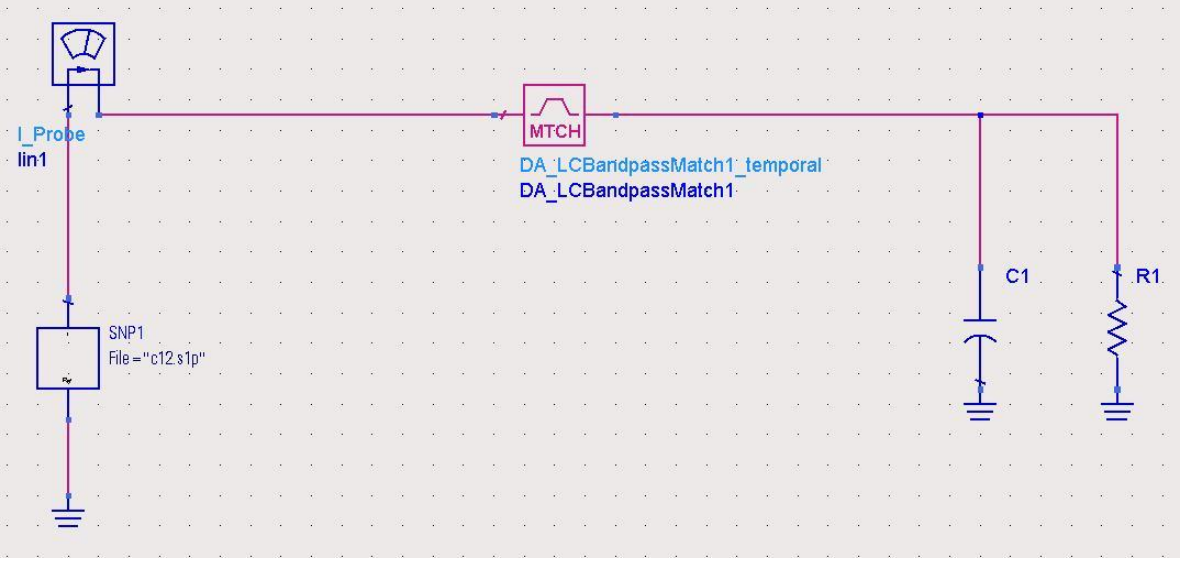

Fig. 4.3.3.1 Example circuit and Band pass matching component.

Although this component is placed in a circuit context, to generate the impedance matching circuit is not necessary that the component terminations are connected to any node, this is just done for further simulations, where the matching component replaces a whole (matching) circuit. When we deploy the menu of impedance matching (Fig. 4.3.3.1), we can enter the necessary parameters that will be implemented internally as well as the creation of the adaptation circuit.

Once we have defined our matching circuit, whose values were optimized according to our application bands, the next step is to optimize the whole set (adaptation circuit and rectifying circuit) to achieve our goals.

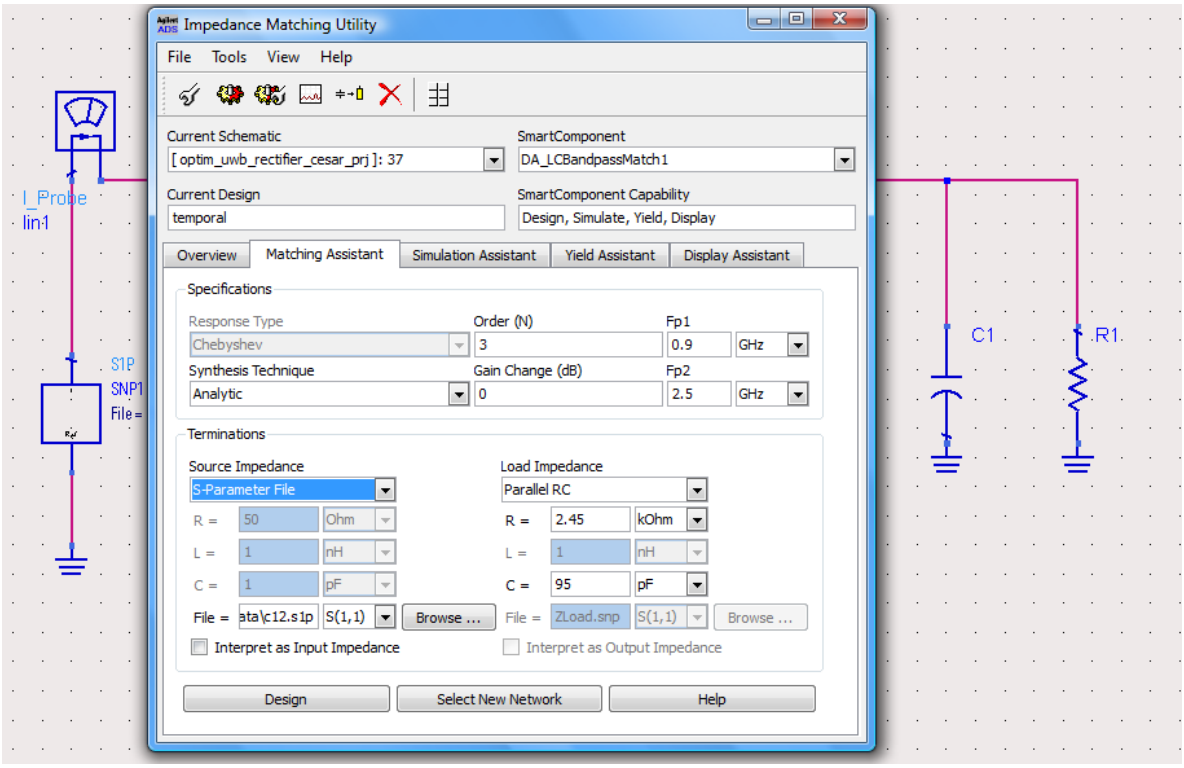

Fig. 4.3.3.2: Impedance matching assistant window. Main parameters to the filled: Lower Frequency (Fp1), Upper Frequency (Fp2). Source / Load Impedance

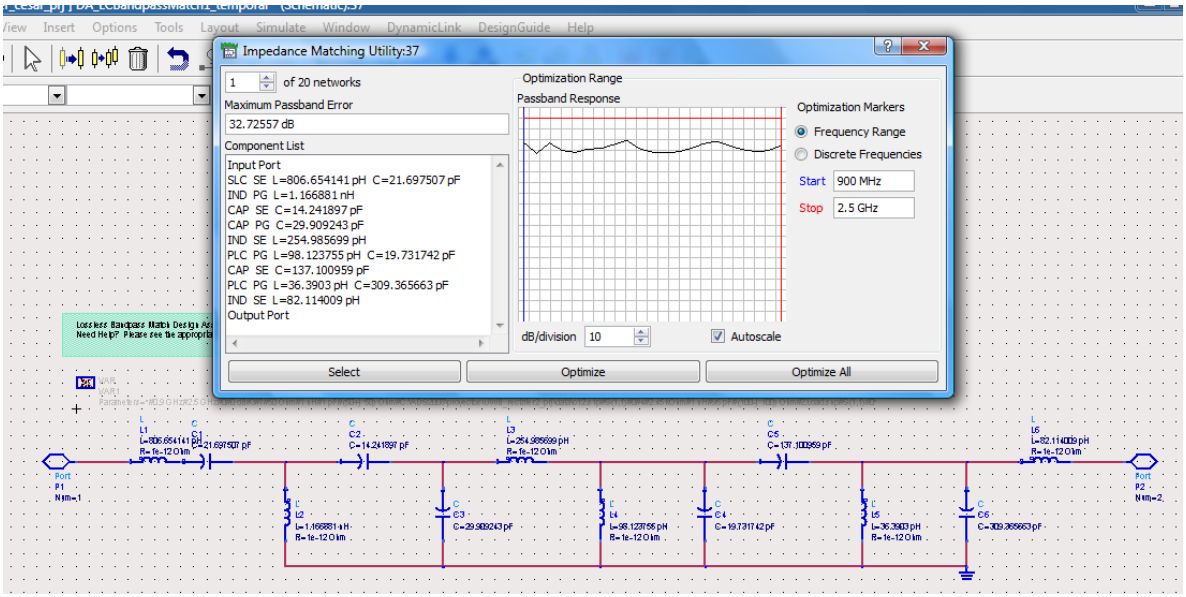

Fig. 4.3.3.3 automatically generated matching circuit. Note that there is more than one generated network.

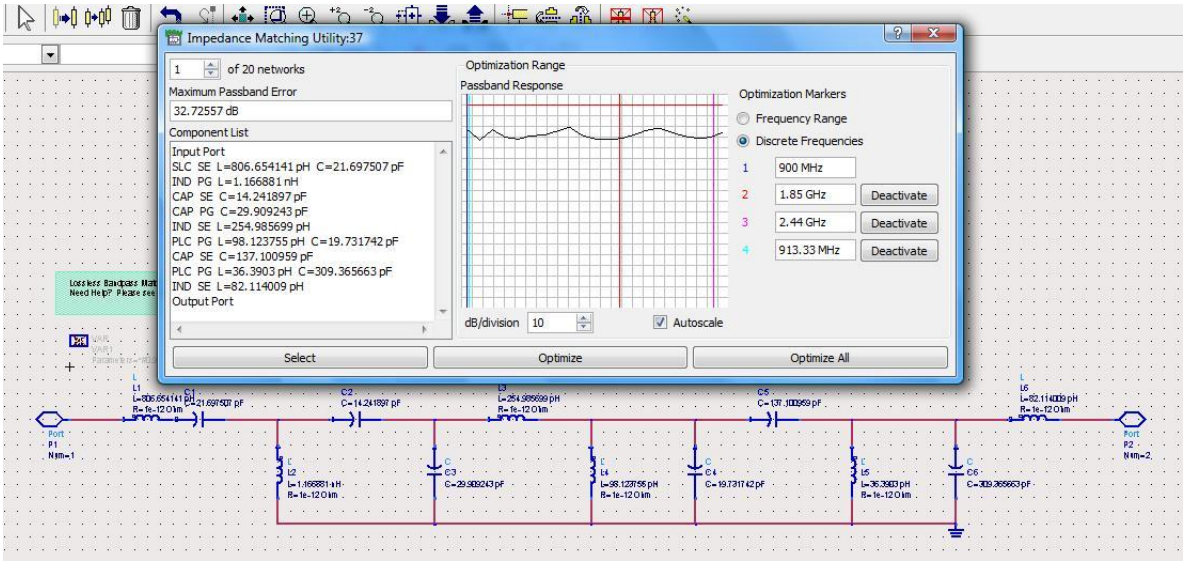

Fig. 4.3.3.4: Post Optimization for best performance in our application bands.

4.3.4 Nominal Optimization

Nominal optimization (also called Performance Optimization) is a technique to design a circuit where, under specific performance goals and a value-search method, the values of each component (or a set) are modified and then simulated, if the result of this simulation does not meet the goals, values are "searched" and simulated again until performance goals are achieved. The value-search method used for this application was the Gradient Search.

4.3.5 Gradient Search Method

The method of gradient search, adjust a set of variables according to an error function and its gradient. The simulator in the first iteration evaluates the error function and its gradient, and then the set of variables will be moved in the direction of the gradient of the error so that the error function is minimized. The simulation stops automatically when the goals are reached, when the iteration limit is reached or when there is a gradient zero. The error function used by the gradient method is the Least-Squares error function.

4.4 Simulations

Once explained the methods used for analysis and simulation of our circuits, we will show the simulations results and analysis for specific rectifier circuits. In this study we have simulated seven rectifiers that can be classified in three groups:

- Series diode rectifiers

- Parallel diode rectifier
- Two diode rectifier.

Moreover, a study of the first two groups has been made showing the differences between different methods of adaptation and different frequency bands of use.

4.4.1 Parasitic

To characterize the diode and capacitor, we took into account the parasitic. Parasitic are mechanical and electrical unwanted characteristics that limit the circuit performance. The notation used in the parasitic components is as follows

- Lp: Is an inductor placed in series with the component and can be explained as the inductance associated with the external terminations of metal that connect the internal component with the (external) circuit.
- Cp: Capacitance that is placed in parallel with the component and is due that all package solid materials have dielectric constants related that behave as capacitors.
- Rp: The metal conductor used to connect the internal component with the (external) circuit is usually a gold or gold plated with an associated very low resistance. This resistance can affect the performance of a microwave circuit.

4.4.2 Series diode rectifier matched with the ADS2008 matching utility and focusing on 900 MHz, 1.85 GHz and 2.45 GHz bands.

After optimizing the values of each component in Fig. (4.4.2.1) to achieve the maximum performance, we have obtained the values shown in Table 4.4.2.1.

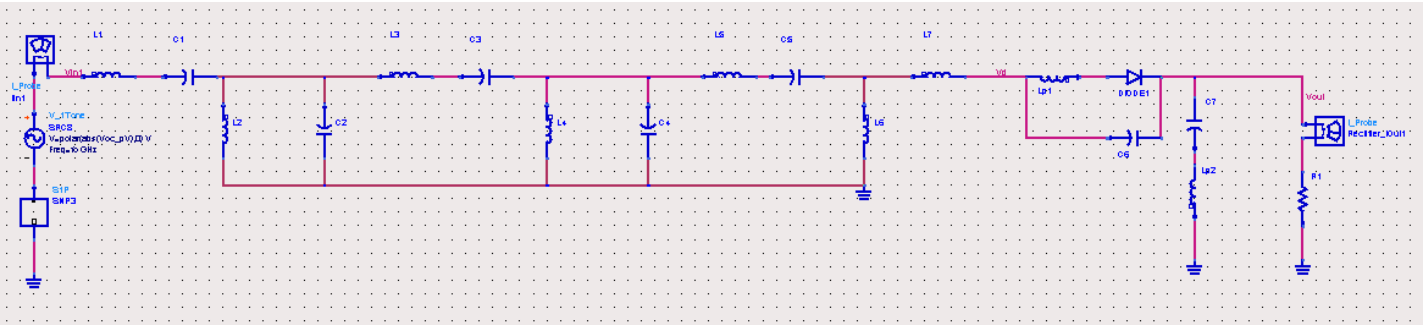

Fig. 4.4.2.1: Complete schematic: antenna S parameters, matching circuit and series diode rectifier.

Fig. 4.4.2.2 shows that the maximum efficiency for the 900 MHz, 1.85 GHz and 2.45 GHz bands is achieved when the received power is -6 dBm, -4 dBm and -6dBm respectively; we can also conclude that the maximum efficiency is 52%, 62% and 59% respectively. If we

observe the efficiency for low input power (-20 dBm), we can note that the values are 25%, 30% and 28% respectively. The main disadvantage of this circuit is the large number of components (18), if we would implement it, the soldering loss of each component would affect the performance significantly.

Table 4.4.2: Simulation values for Fig.4.4.2

Component Name	Value	Component Name	Value
L1	3.3 nH	**C1**	2.2 pF
L2	6.8 nH	**C2**	1.8 pF
L3	16 nH	**C3**	1 pF
L4	12 nH	**C4**	1.2 pF
L5	15 nH	**C5**	0.5 pF
L6	36 nH	**C6**	68 pF
L7	15 nH	**Cp1**	0.25 pF
Lp1	0.6 nH	**R1**	2.2 KOhm
Lp2	0.36 nH		

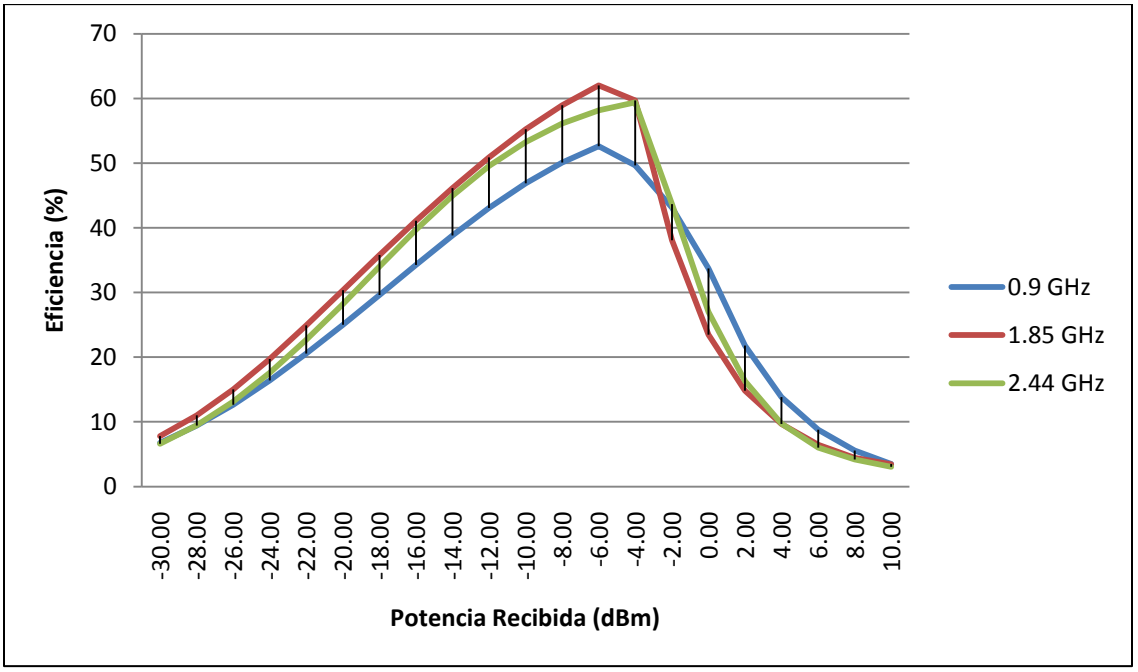

Fig. 4.4.2.2: Rectenna efficiency versus input power showing the behavior for low input power (Agilent ADS).

4.4.3 Series diode rectifier matched with LC circuit over the entire band.

After optimizing all the values of each component in Fig. (4.4.3.1) to achieve the maximum performance, we have obtained the values shown in Table 4.4.3.1.

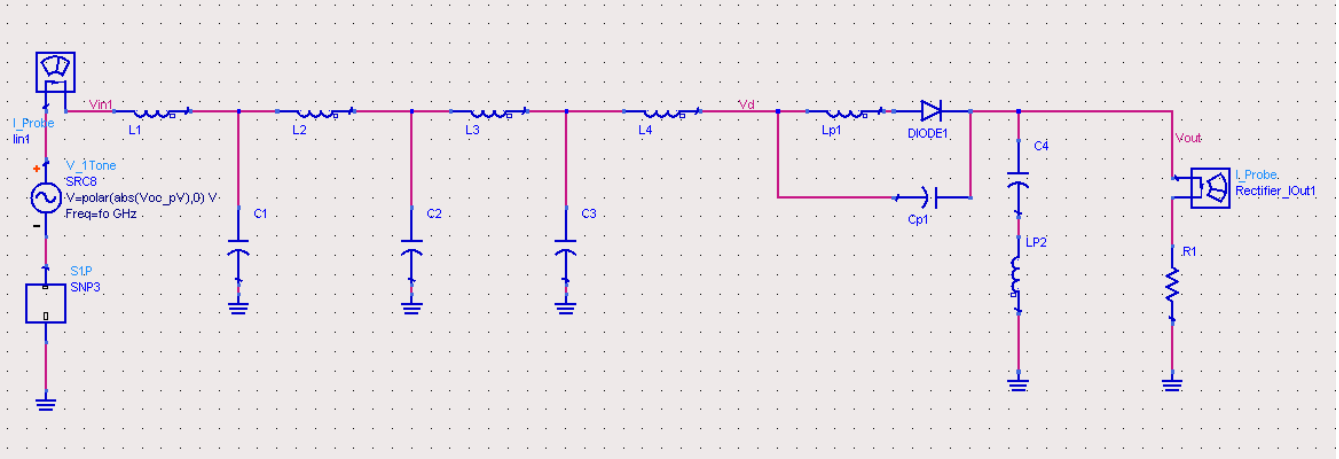

Fig. 4.4.3.1: Complete schematic: antenna S parameters, matching circuit and series diode rectifier.

Fig 4.4.3.2 shows that the maximum efficiency for the 900 MHz, 1.85 GHz and 2.45 GHz bands is achieved when the received power is -2 dBm. We can also conclude that the maximum efficiency is 44%, 41% and 50% respectively. If we observe the efficiency for low input power (-20 dBm), we can note that the values are 15.5%, 8.9% and 11% respectively, well below the Fig. 4.4.2.1 rectifier. The drop in efficiency has been remarkable, and this is because the matching over a broad band is more complicated.

Table 4.4.3: Simulation values for Fig. 4.4.3.1

Component Name	Value	Component Name	Value
L1	4 nH	**C1**	1 pF
L2	1 nH	**C2**	1 pF
L3	14 nH	**C3**	1 pF
L4	30 nH	**C4**	140 pF
Lp1	0.3 nH	**Cp1**	0.25 pF
Lp2	0.36 nH	**R1**	2.2 KOh

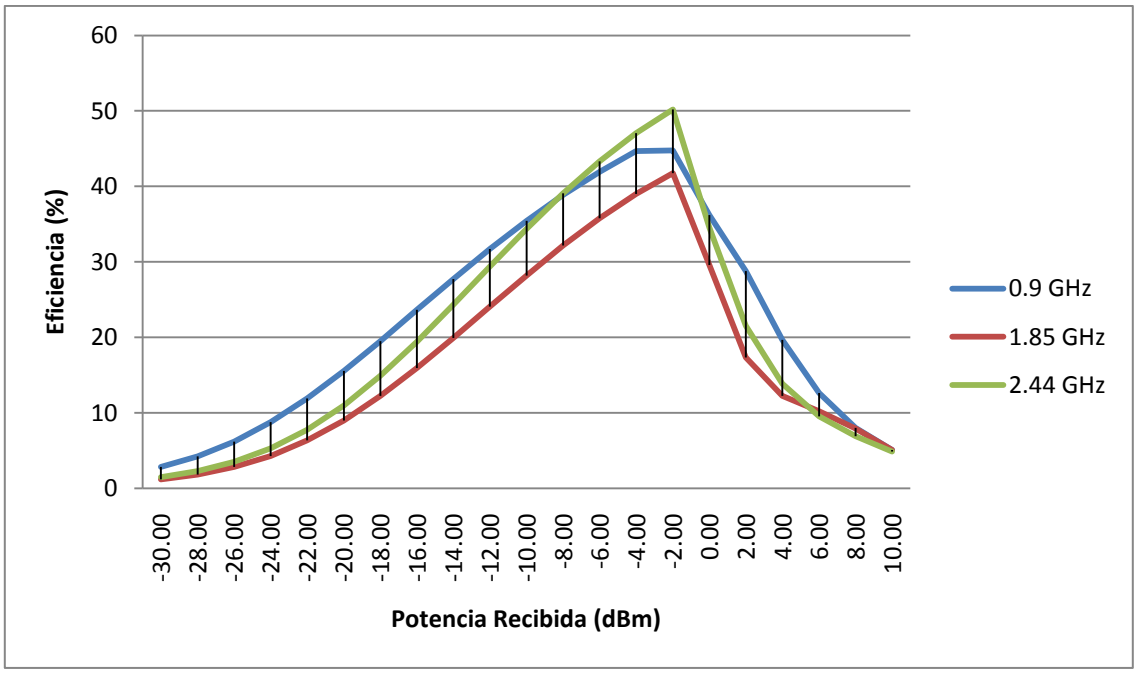

Fig. 4.4.3.2: Rectenna efficiency versus input power for low input power (Agilent ADS) at 900 MHz, 1.85 GHz and 2.45 GHz.

4.4.4 Series diode rectifier matched with LC circuit focusing on the bands of use.

After optimizing the values of each component in Fig. (4.4.4.1) to achieve the maximum performance, we have obtained the values shown in Table 4.4.4.

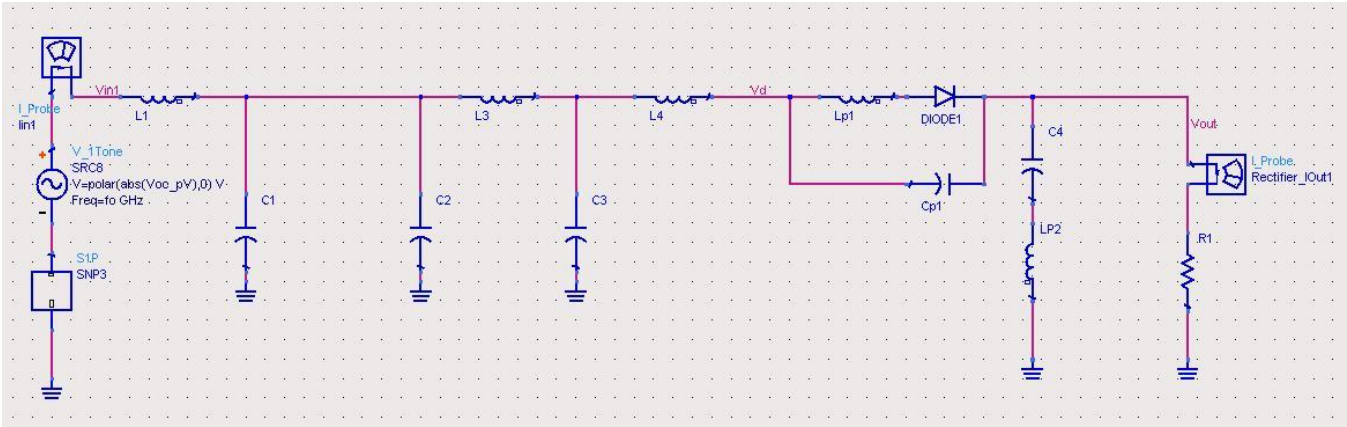

Fig. 4.4.4.1: Complete schematic: antenna S parameters, matching circuit and series diode rectifier.

Fig. 4.4.4.1 shows that the maximum efficiency for the 900 MHz, 1.85 GHz and 2.45 GHz bands is achieved when the received power is -4 dBm, -2dBm, -4dBm respectively. We can also see that the maximum efficiency is 49.2%, 44.9% and 59.8% respectively, higher than the last network. If we observe the efficiency for low input power (-20 dBm), we can note that the values are 18.7%, 13.3% and 20.9% respectively. This circuit would be a good

balance between efficiency and component amount, as the circuit of Fig. 4.4.2.1 has many components but has a very good performance and the circuit of Fig. 4.4.3.1 has few components and low performance as the band is very extensive. However, in this circuit, we have the advantage that it has fewer components than the other two shown above and also you get an acceptable efficiency.

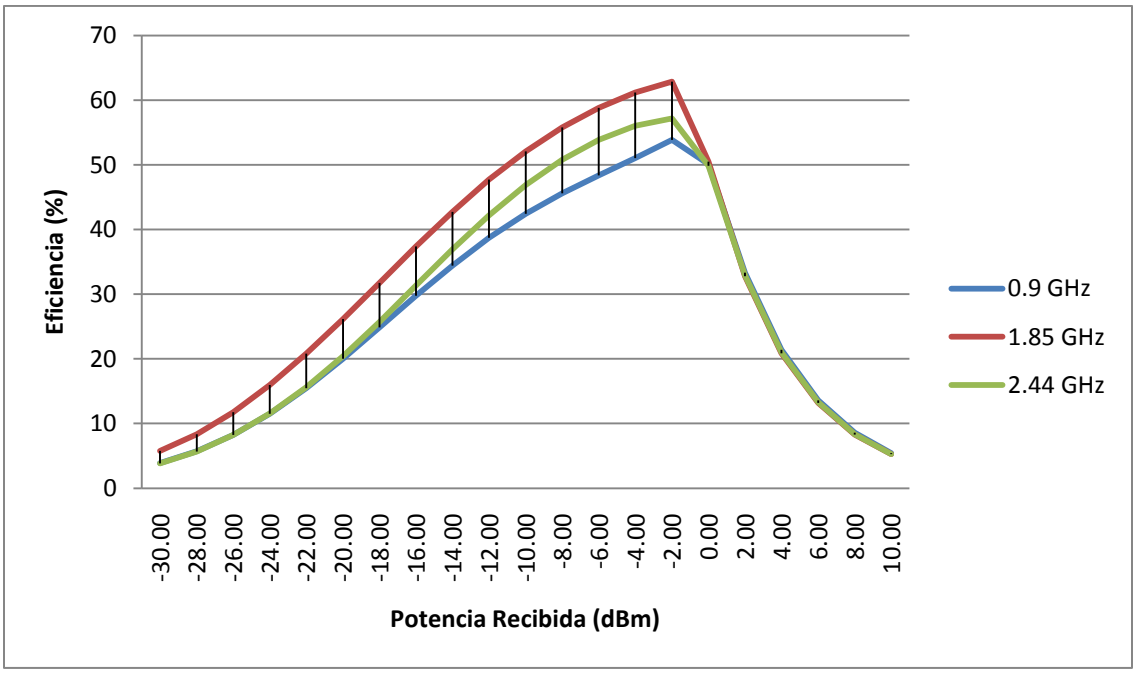

Fig. 4.4.8.2: Rectenna efficiency versus input power for low input power (Agilent ADS) at 900 MHz, 1.85 GHz and 2.45 GHz.

4.5 Efficiency Analysis for Low Input-power.

After analyzing the efficiency of each band in a power range, we will now analyze the efficiency when the received power is -20 dBm (which is a good example of an electromagnetic signal in the environment) and for frequencies ranging from 500 MHz to 3 GHz.

Fig. 4.5.1 (a) shows the efficiency of the rectifiers that have been adapted using the ADS2008 matching utility. A better performance is appreciated in the series rectifier; the parallel diode rectifier, shows an efficiency about 13% less for all bands while the two diode rectifier, in the 900 MHz, 1.85 GHz and 2.45 GHz bands has an efficiency of 8%, 5% and 8% respectively, lower than the series diode rectifier. As explained above, the difficulty with this method of adaptation is the great quantity of components required and the consequent loss of performance when soldering. Fig. 4.5.1 (b) shows the efficiency versus frequency for the rectifiers adapted with LC circuits and for all 700 MHz- 2.5 GHz band, we can observe that the results are similar but less efficient than other methods of adaptation, improved efficiency is achieved with the rectifier diode series that has reached about 5% higher efficiency than the parallel rectifier diode; this low efficiency is the result of adapting a broad band of frequencies with a limited number of components. Fig. 4.5.2 shows the efficiency of the rectifier adapted with LC circuit over the bands of interest, again we see that a higher performance was obtained with the series diode rectifier diode,

this is because it is more feasible to adapt rectifier using the same number of components to smaller frequency bands.

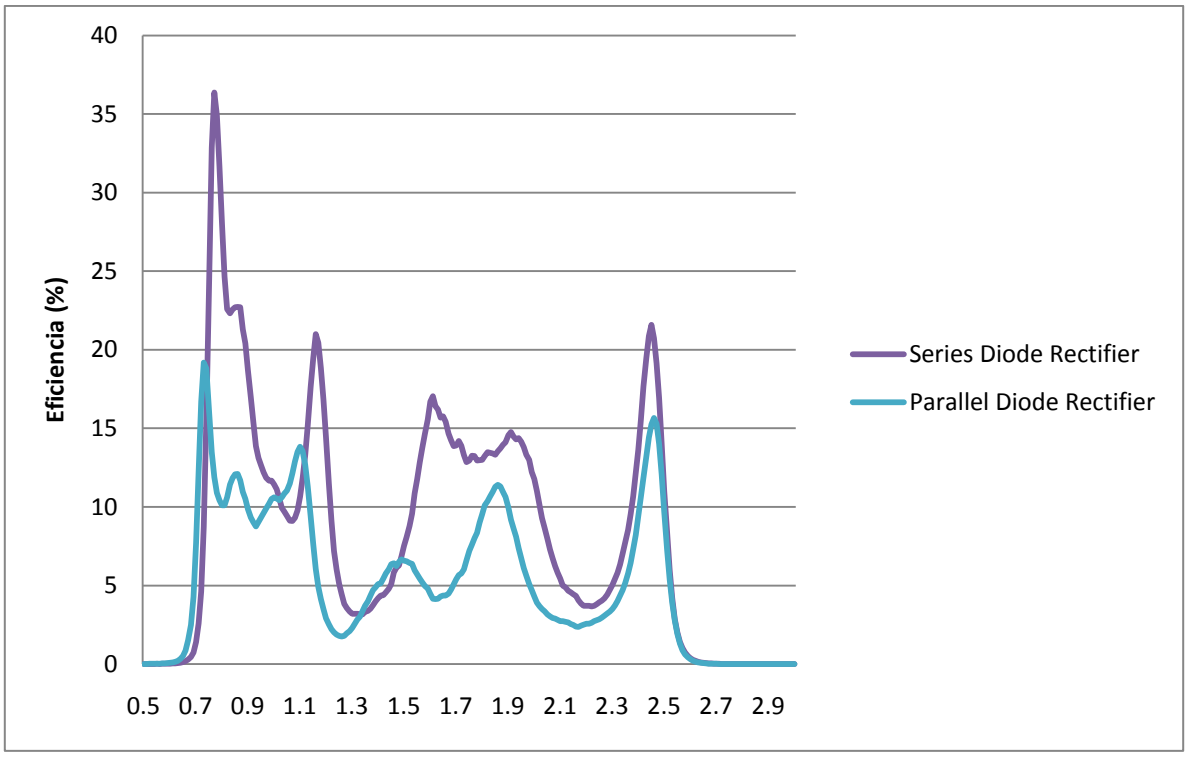

Fig. 4.5.2: Efficiency versus frequency for -20dBm input power for the rectifiers adapted with LC circuit with focus over the 900 MHz, 1.85 GHz and 2.45 GHz bands

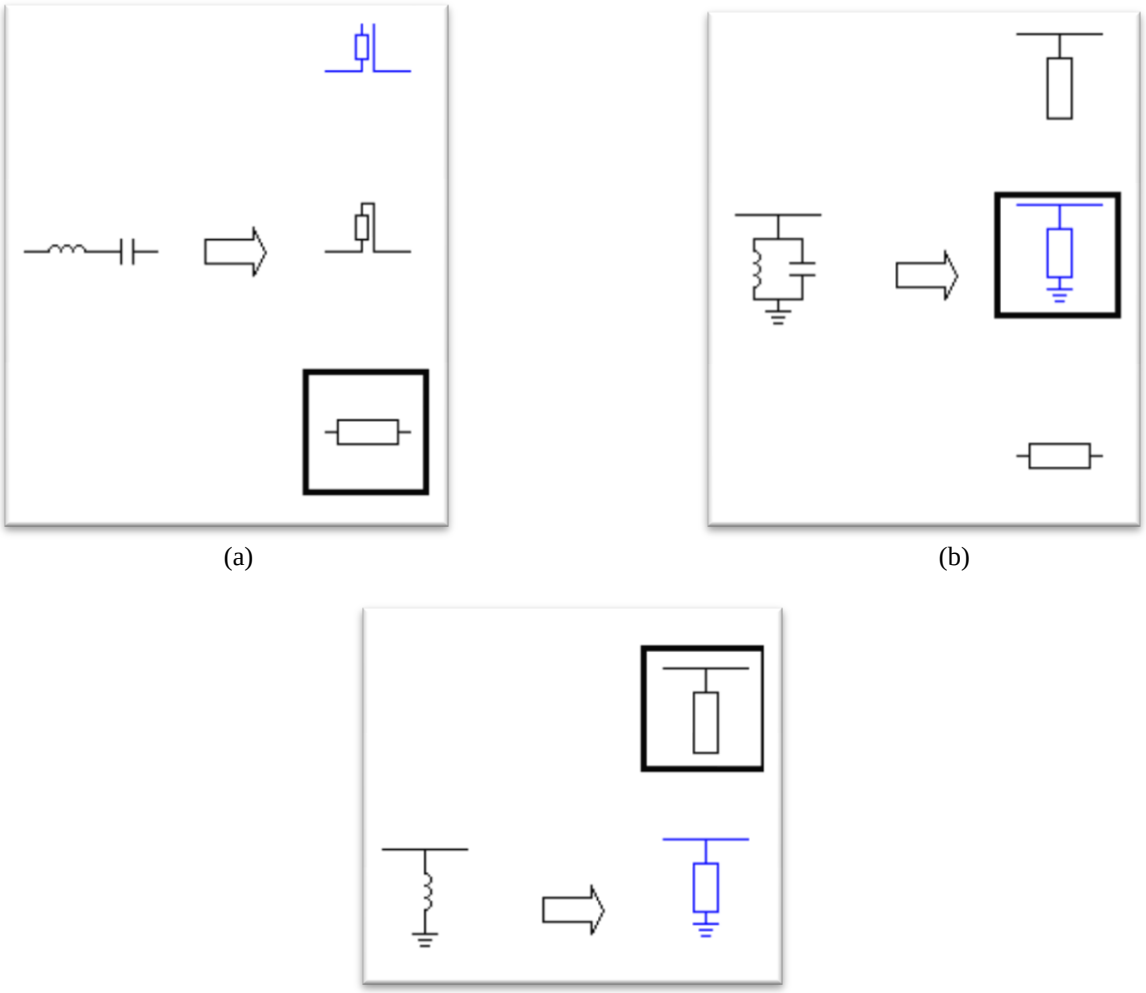
4.6 LC to Microstrip-Lines Transformation

According to the simulations shown above, the series diode rectifier was chosen to proceed with the application for showing the best performance in simulations; the problem now would focus on choosing the proper matching method. Given the low efficiency of the rectifier circuit adapted with LC elements, we have decided to improve the rectifier adapted with the ADS2008 matching utility but with a LC-Microstrip line transformation to avoid the effects of soldering and to exploit the characteristics of microstrip lines.

Fig. 4.6.1 shows the equivalence for the transformation from LC elements to microstrip lines; we can see that the series inductor and capacitor have been transformed into a transmission line, the parallel grounded inductor and capacitor have been transformed into a grounded parallel stub and the parallel grounded inductor has been transformed into a not grounded parallel stub. Fig. 4.6.1 shows the complete circuit schematic where the inductors and capacitors have been transformed into transmission lines.

To improve the efficiency of our circuit, the techniques of harmonic balance and nominal optimization were applied again. In this case, the parameters that were optimized were: the lengths and widths of each transmission line, the inductor value, the rectifier capacitor and the load resistance. Table 4.6 shows the final values of optimization. Fig. 4.6.2 shows the

efficiency as a function of the frequency when the input power is -20 dBm, a good example of electromagnetic signal in the environment.



(a) (b) (c)

Fig. 4.6.1: (a) series inductor and capacitor (b) parallel grounded inductor and capacitor (c) parallel grounded inductor possible transformations, components in a box were selected

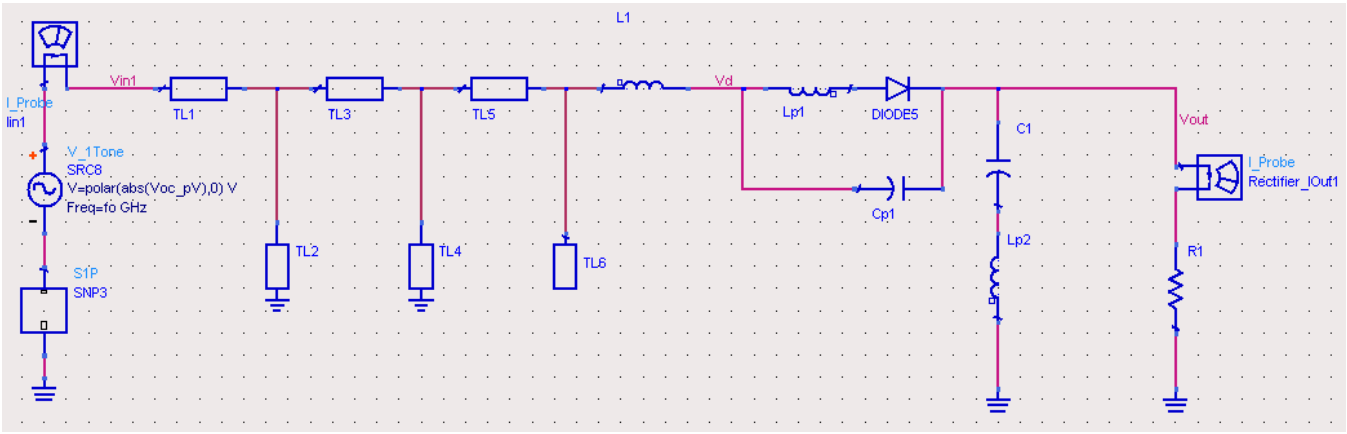


Fig. 4.6.2: Complete schematic: antenna S parameters, matching microstrip lines and the series diode rectifier.

The Fig. 4.6.3 also shows a comparison of efficiency as a function of frequency between the classical LC circuit components and the new transmission lines circuit. We can observe that the efficiency is almost identical with the exception of some small details such as that the implementation of transmission lines has improved by 5% the 900 MHz band performance and the 1.85 GHz band shows efficiency drop of 4%.
In Fig. 4.6.4 a comparison of the efficiency as a function of received power shown, we can observe that the maximum efficiency for 900 MHz, 1.85 GHz and 2.45 GHz is achieved when the received power is -6 dBm, - 6 dBm and -4 dBm respectively and the efficiency at this values are 48.6%, 64.8% and 53.6% respectively.

Table 4.6: Simulation values for Fig. 4.6.1

Component Name	Value	Component	Value
L1	12 nH	**TL5**.L	2.7 cm
TL1.L	3.2 cm	**TL5**.A	0.3 mm
TL1.A	3.5 mm	**TL6**.L	0.25 cm
TL2.L	2.7 cm	**TL6**.A	1.8 mm
TL2.A	0.4 mm	**C1**	100 pF

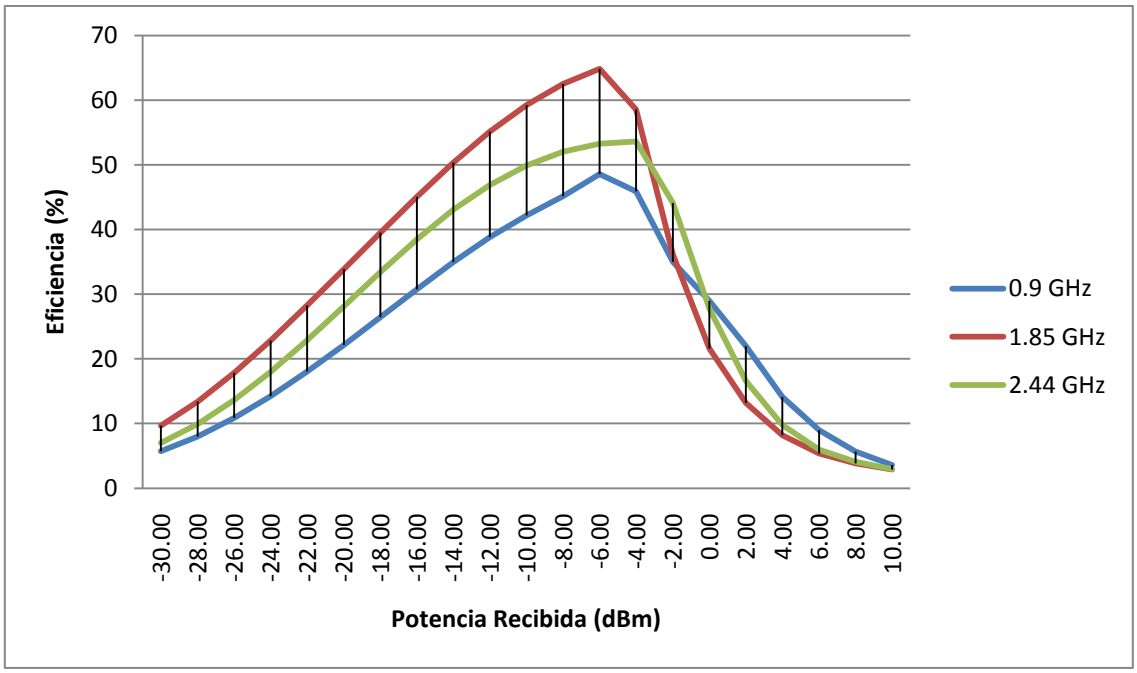

Fig. 4.6.4: Rectenna efficiency versus input power for low input power (Agilent ADS) at 900 MHz, 1.85 GHz and 2.45 GHz.

4.6.1 Momentum

Momentum is an electromagnetic simulator that computes S-parameters for various topologies such as ours that presents vias (holes that connect two layers of the topology). This tool is very useful to predict circuit performance at high frequencies and one of the main advantages of momentum is that, from a schematic, you can create a physical layout to simulate the characteristics of the substrate and also allocate the necessary ports to simulate the different components of our circuit. Momentum is based on the numerical discretization method called method of moments.

In general, the method of moments, fragments transmission lines into smaller segments to find the current distribution in each of these, so at the end of the simulation, we can know the joint behavior of these to characterize the entire system.

4.6.2 Momentum Layout

Once we have the LC component values optimized as well the transmission lines lengths, the next step is to generate the layout of our matching circuit to simulate the transmission lines together with the substrate. In Fig. 4.6.2.1 the auto generated matching circuit layout is shown.

According to the values in Table 4.6, the lengths of transmission lines L1, L3 and L5, are 3.2cm, 2.7cm and 2.7cm respectively, giving a total of 8.6cm.

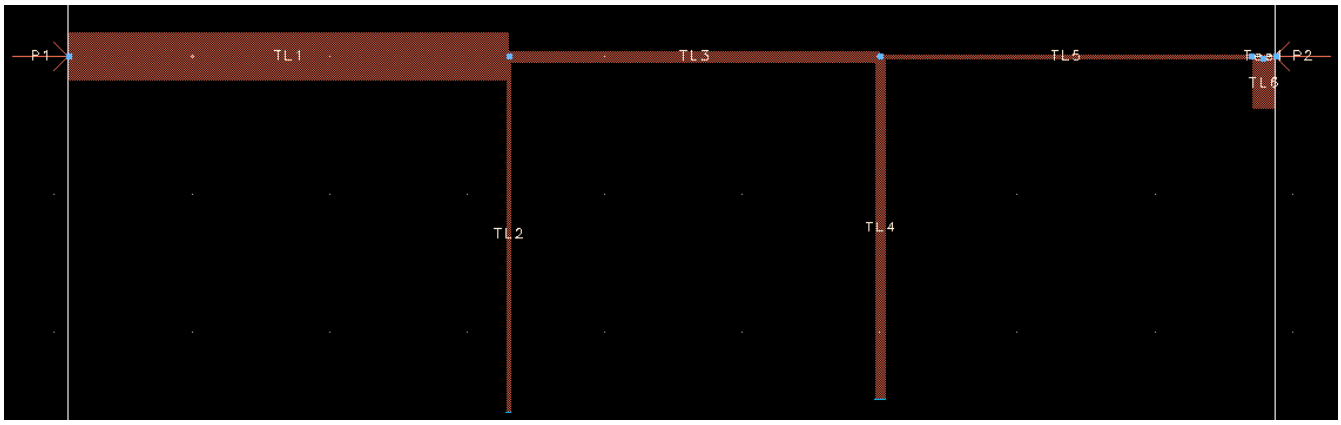

Fig. 4.6.2.1: auto generated matching circuit layout by ADS2008 Momentum

To improve the circuit size and make it more compact, a technique has been applied; we have kept the lengths of the transmission lines but instead of straight lines we have used curved transmission lines. The measures of the complete layout with straight lines were: 8.75cm x 2.75cm, while the measurements of the size-improved layout are: 2,97cm x 2.31cm, 66% and 16% shorter.

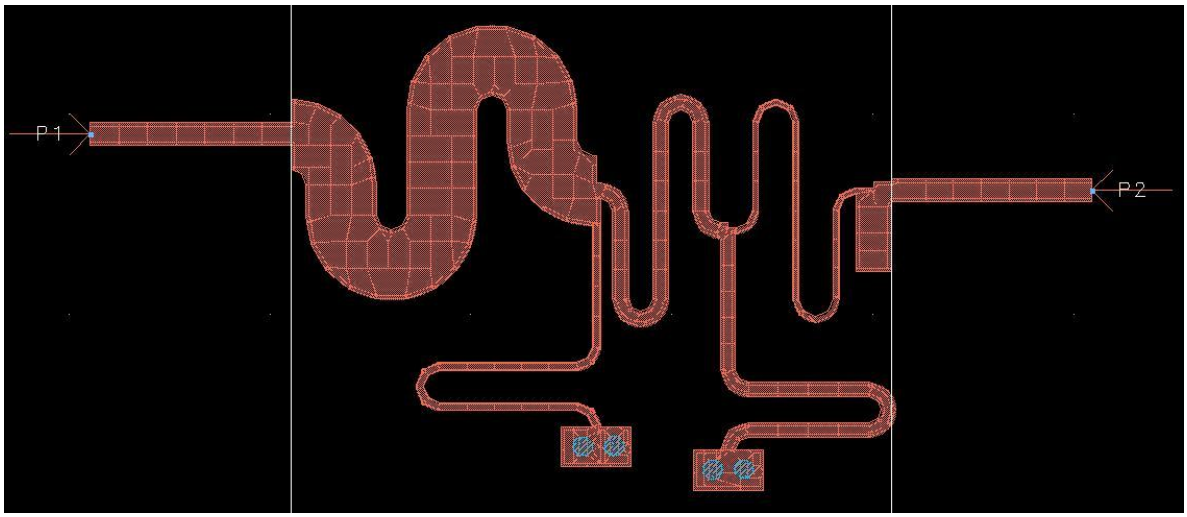

Fig. 4.6.2.2: size-improved matching circuit and momentum meshing.

In Fig. 4.6.2.1 and 4.6.2.2, we can observe that the ground lines are different, this is because the ADS2008 generates an ideal model of ground connection, which is not desirable when simulating since the simulations should adjust to real parameter, what is we really want, that's why in Fig. 4.6.2.2 the ideal ground has been replaced by a transmission line with two vias that connects the top layer with the ground plane through the

substrate. This hole will be subsequently filled with a conductor paste; this will be discussed in detail in Section 4.7.

Since the results after simulating with Momentum could be different and therefore not reach the goals, some adjustments in the transmission lines should be made; we have seen empirically that by adjusting the length of the third stub, the 2.45 GHz band moves to the right or the left if ,respectively, the length decreases or increases. A similar behavior has been observed in the other stubs, so that the efficiency for the frequency bands has been adjusted successfully. Fig. 4.6.2.3 shows the efficiency as a function of frequency for the rectifier with the data that Momentum has generated. To implement momentum data in the simulation of the entire circuit, the implementation of a data module is necessary. Fig. 4.6.2.4 shows the module has been implemented.

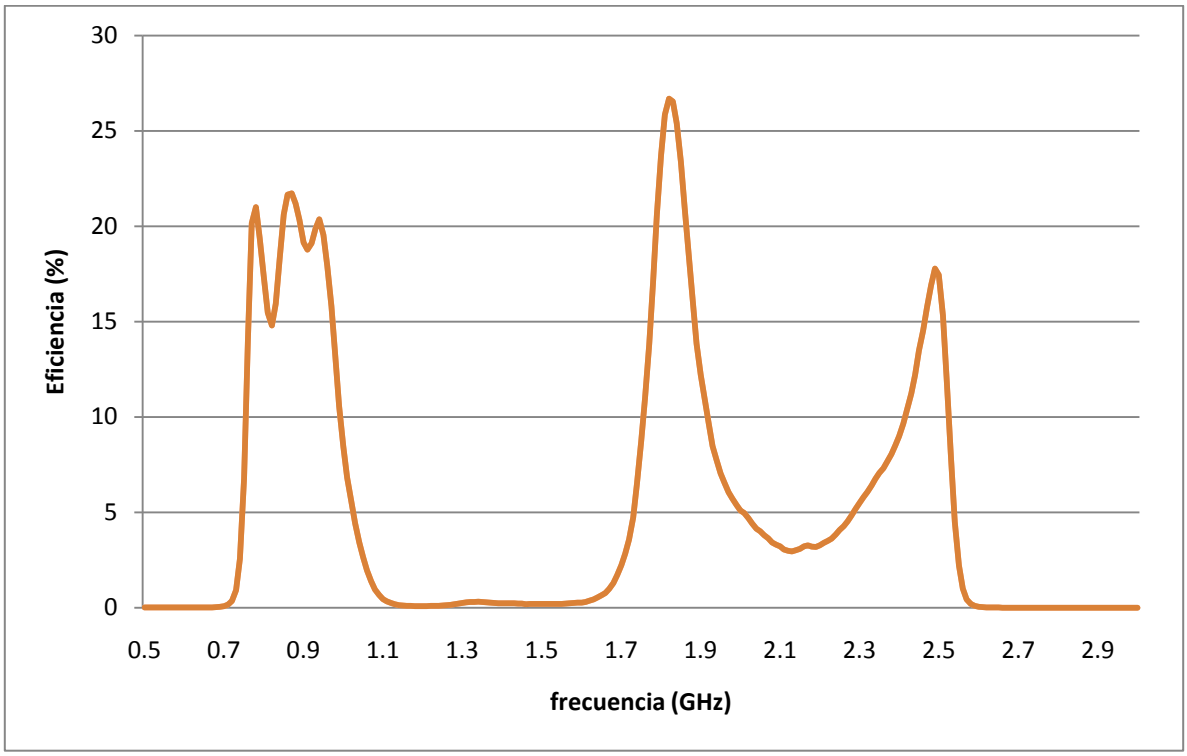

Fig. 4.6.2.3: Efficiency versus frequency showing the behavior for -20dBm input power with the matching circuit Momentum data implemented.

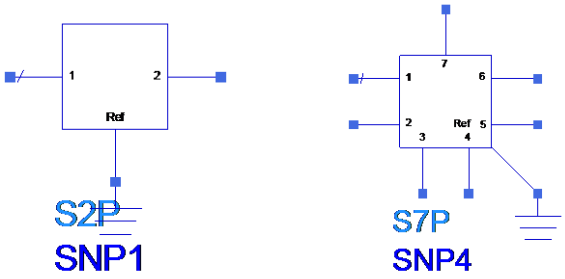

Fig. 4.6.2.4: 2 and 7-port S-Parameter module, the data generated by Momentum is loaded into these items and then simulated with the other circuit components.

The rectifier layout was designed based on the measurements of the components to be attached. Fig. 4.6.2.5 shows the layout of the rectifier that, for the schematic simulation, components such as diodes, inductors, capacitors and resistors are replaced by ports; each of these ports corresponds to one pin of the module data (Fig. 4.6.2.4) in the schema.

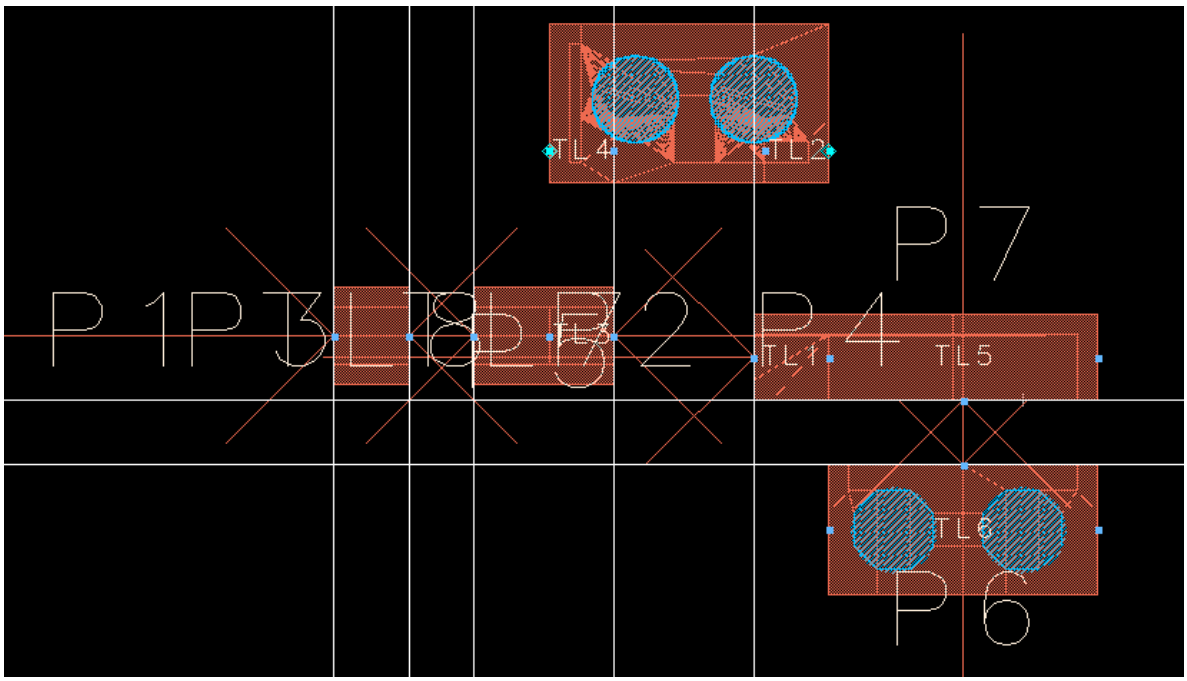

Fig. 4.6.2.5: Rectifier layout, the dimensions are 7.1 x 5.3mm

Fig. 4.6.2.6 shows the complete schematic with the integrated data modules. The first module, has the matching circuit momentum simulation data, the second module, has the momentum simulation data of the transmission lines of the rectifier, so that the ports that had been placed before in the layout now are in the respective pins on the module to simulate with the components.

Fig. 4.6.2.7 shows the efficiency versus frequency, we can observe that the maximum efficiency for the 900 MHz, 1.85 GHz and 2.45 GHz bands is about 20%. Fig. 4.6.2.8 shows the efficiency for the power received, we can see that for the bands mentioned above, the maximum efficiency is 48.6%, 64.8% and 53.6% respectively and are achieved when the received power is of -6 dBm,-4dBm and -6dBm respectively.

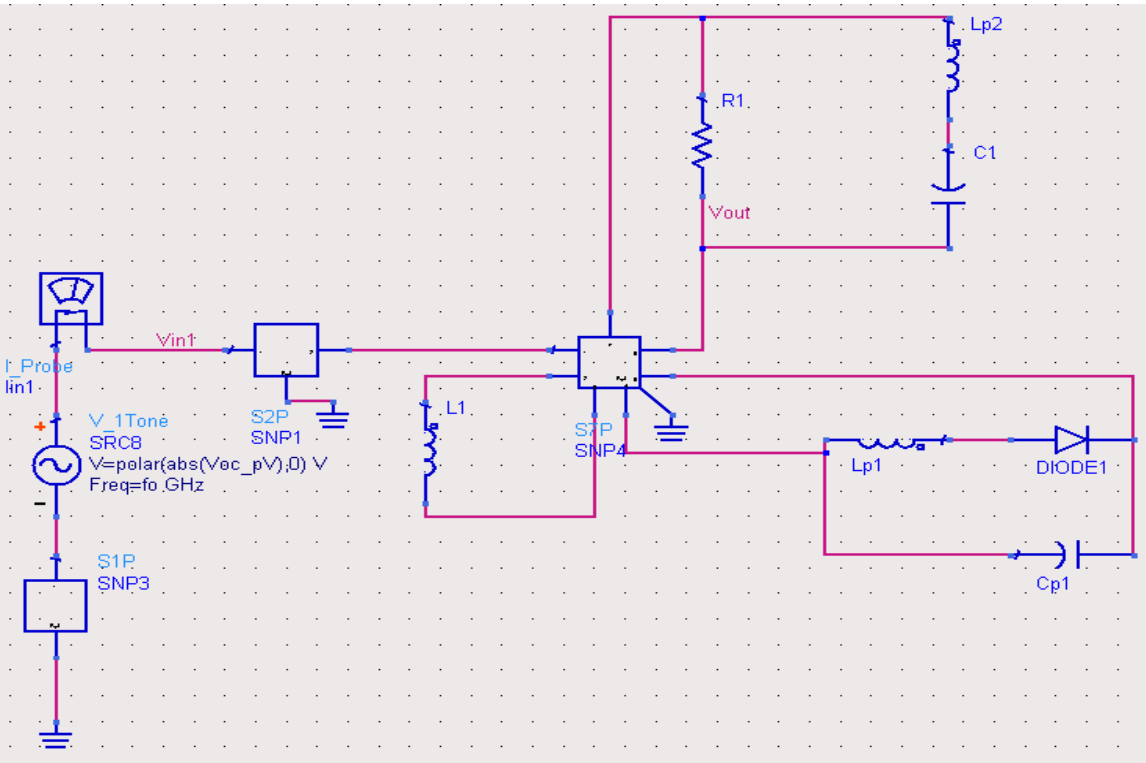

Fig. 4.6.2.6: Complete final schematic including matching lines and rectifier transmission lines momentum data

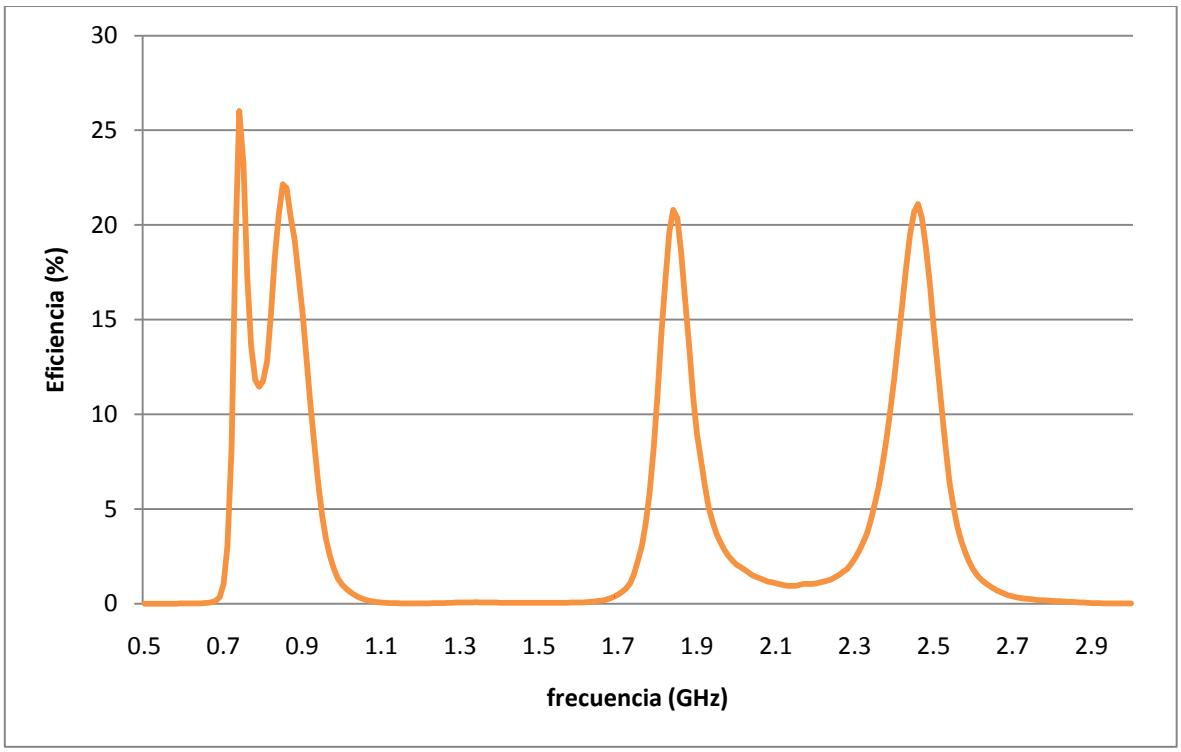

Fig. 4.6.2.7: Efficiency versus frequency showing the behavior for -20dBm input power with the matching and rectifier lines Momentum data implemented.

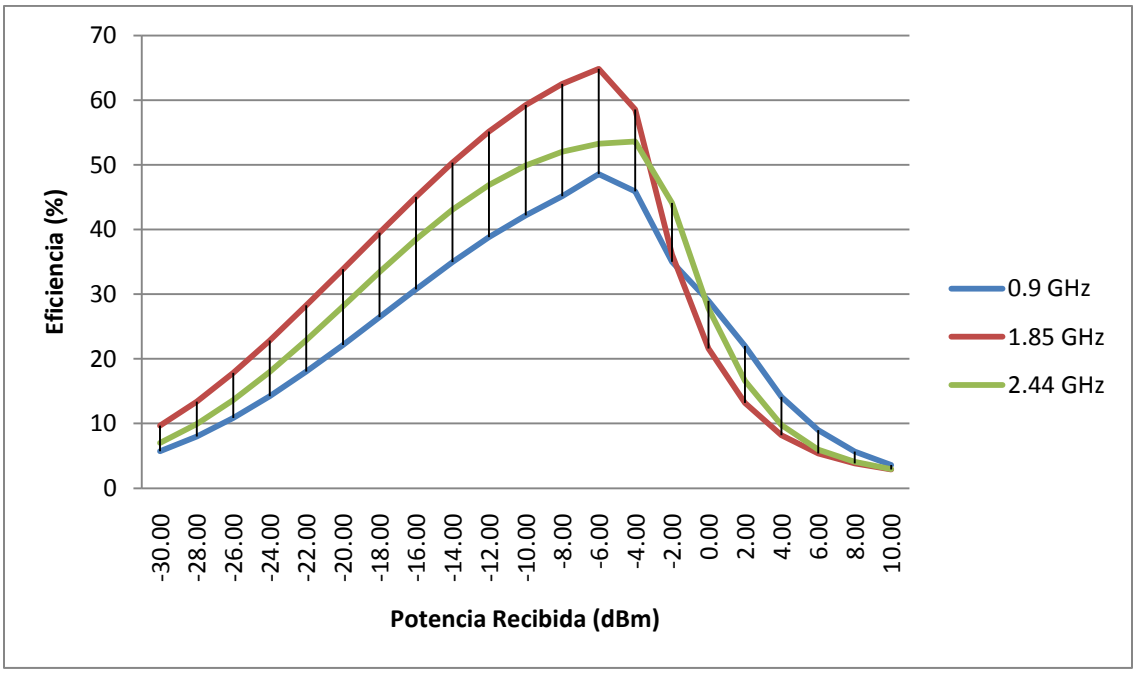

Fig. 4.6.2.8: Rectenna efficiency versus input power for low input power (Agilent ADS) at 900 MHz, 1.85 GHz and 2.45 GHz.

4.7 Rectifier Fabrication and Measurements

The manufacturing process of the rectifier circuit, as it is made from the same substrate as the antenna, is almost the same. The only difference is that to make the VIA holes, we need to follow a procedure called metallization of circuit boards [21]. The first step of this procedure is to protect the circuit with a plastic protective film before drilling the holes. The second step is the application of the LPKF Pro Conduct ® paste that, with the help of a vacuum table to suck it, will coat the walls of the hole. Finally, after removing the plastic protective film, the circuit is introduced in a hot air oven at 160 º C for 30 minutes.

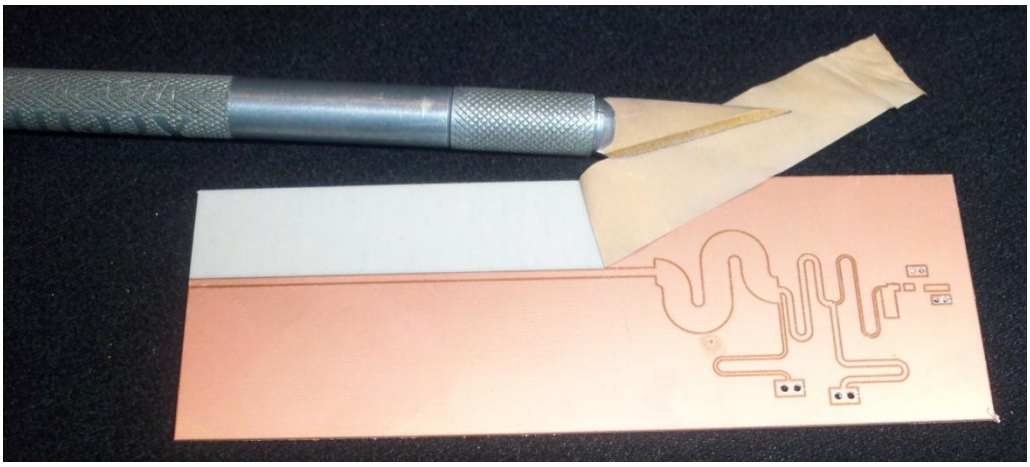

Fig. 4.7.1: Recent fabricated matching-rectifier circuit with copper excess.

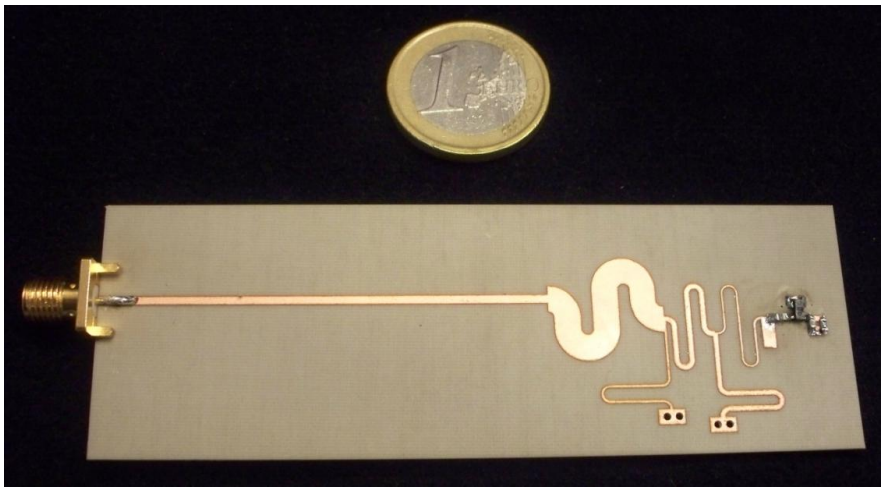
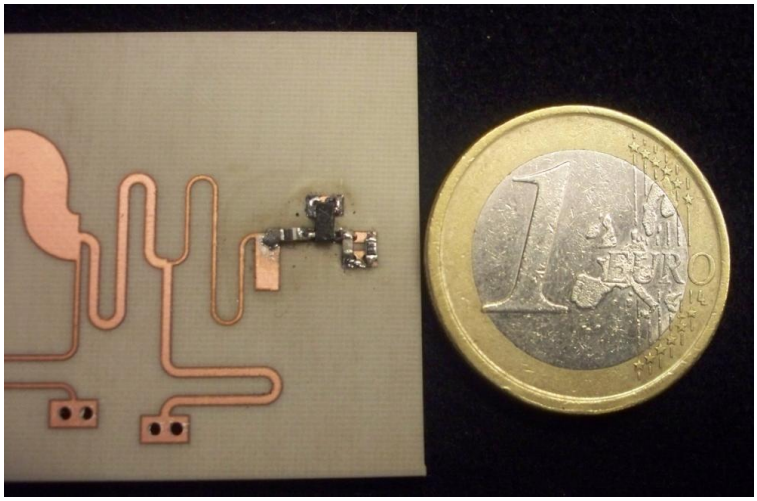


(a)



(b)

Fig. 4.7.2: shows the matching circuit (a), the rectifier circuit (b) and a zoom to the soldered components(c)

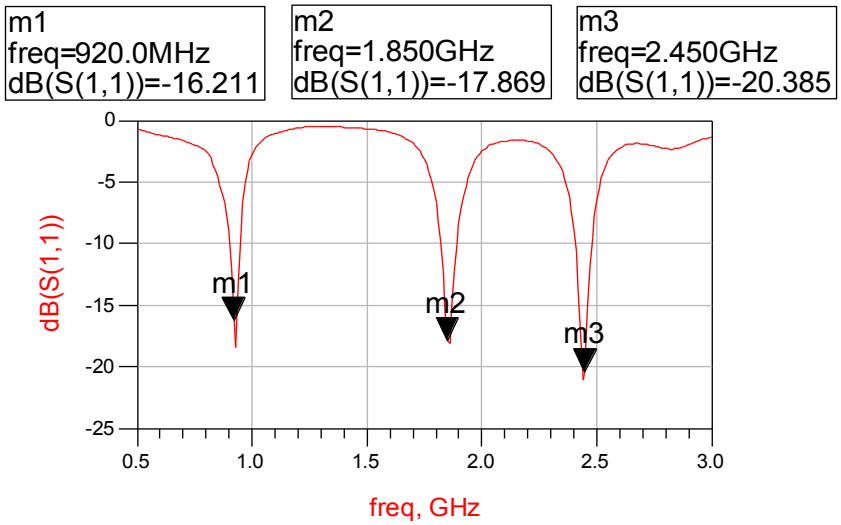


Fig. 4.7.3: shows the S11 parameters of the rectifier.

Fig. 4.7.1 shows, similarly to the antenna fabrication, the way to remove the copper excess that covers the top layer of the substrate with a cutter; and Fig. 4.7.2, as a form of demonstration, shows the dimensions of the newly manufactured circuit compared with a euro coin to the side. Note that the exact measurements have been detailed in section 4.2.6.
The parameters measured and compare with the simulations were the S-parameters (section 4.3.1). To carry out these measurements a Rohde & Schwarz ZVA24 Vector Network Analyzer (VNA) has been used.

Fig. 4.7.4: Rectenna measurement: analog signal generator and multimeter

The measurements for the full rectification circuit were made, therefore, with the matching circuit attached to it. To make these measurements, we used the Agilent E8257D analog signal generator, an Agilent E4407B spectrum analyzer and a Promax MC-859 digital multimeter. The first thing we did was to "calibrate" the cable which would connect the rectifier circuit to the analog signal generator, this is done because minimal DC power is lost in the cable; for this "calibration" the same cable to be used later was connected from the analog signal generator to the spectrum analyzer in order to obtain more accurately delivered power measures from the signal generator. After this, we connect the rectifier to the signal generator, and with the help of a multimeter, the output DC voltage was measured.

Once we have the measurement system ready, we can proceed to take some measures. The measurements were taken as follows:

- An input power sweep, ranging from -25 dBm to 5 dBm for each frequency (900 MHz, 1.85 GHz and 2.44 GHz).
- A frequency sweep, ranging from 800 MHz to 2.5 GHz for an input power of -10 dBm.
- A frequency sweep, ranging from 800 MHz to 2.5 GHz for an input power of -20 dBm.

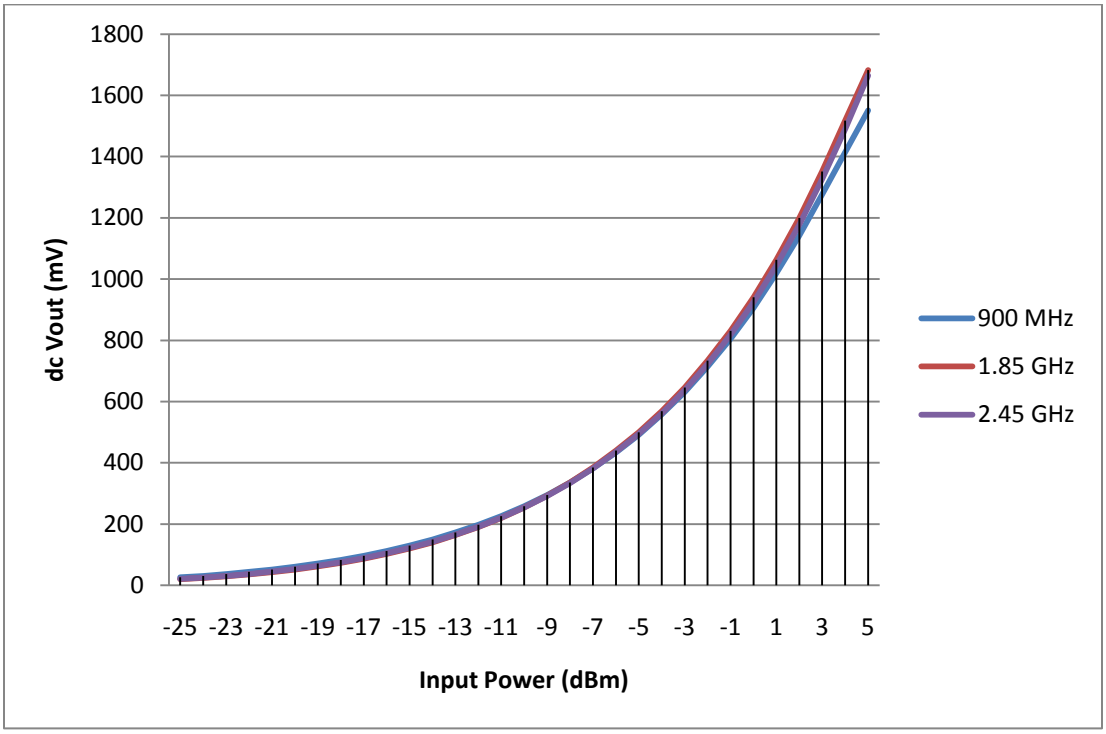

Fig. 4.7.5: Output voltage vs. input power for 900MHz, 1.85 GHz and 2.45GH

Fig. 4.7.4 shows that as we increase the input-power, the DC voltage increases proportionally, but this does not necessarily indicate that the overall efficiency shows the same behavior. This can be justified by observing the Fig. 4.7.5, where the efficiency vs. input-power plot, denotes that for high values of input power, efficiency begins to fall. For efficiency values: First, we calculated the output power by squaring DC voltage measured with the multimeter (which we have previously converted from mV to V) and was then divided by our radiation resistance. Second, we calculated the RF power by transforming the input power from dBm to Watts and finally, we divided the value of the output power by the RF power value.

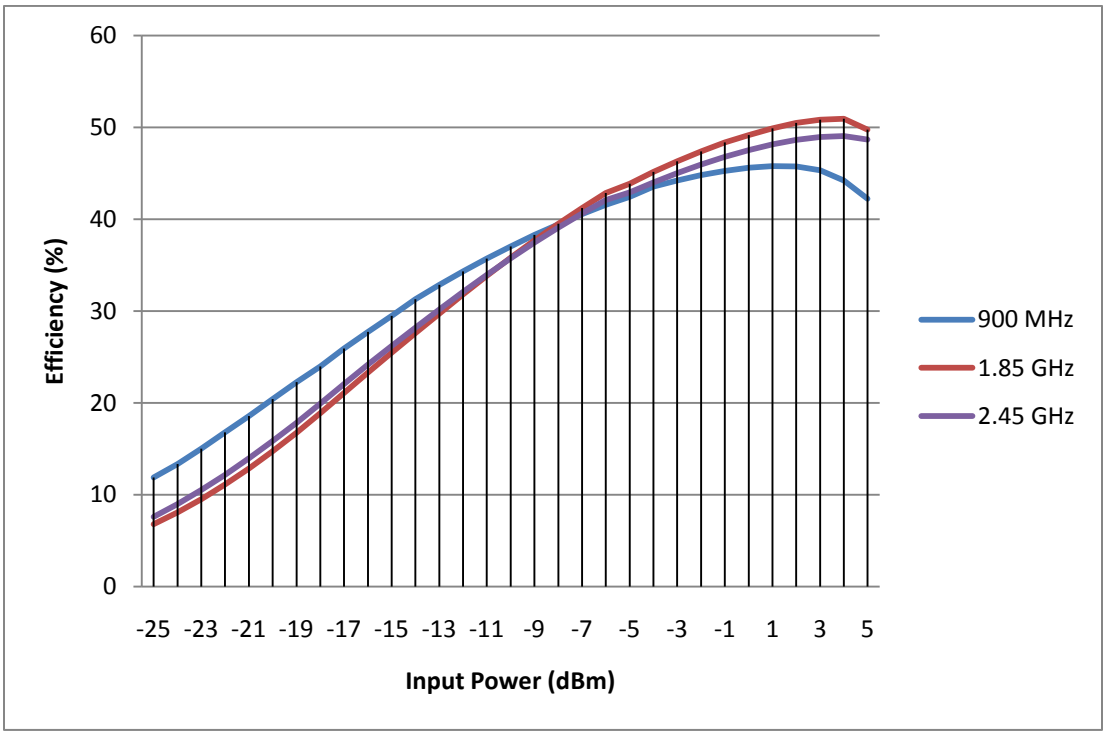

Fig. 4.7.6: Efficiency vs. input power for 900MHz, 1.85 GHz and 2.45GH

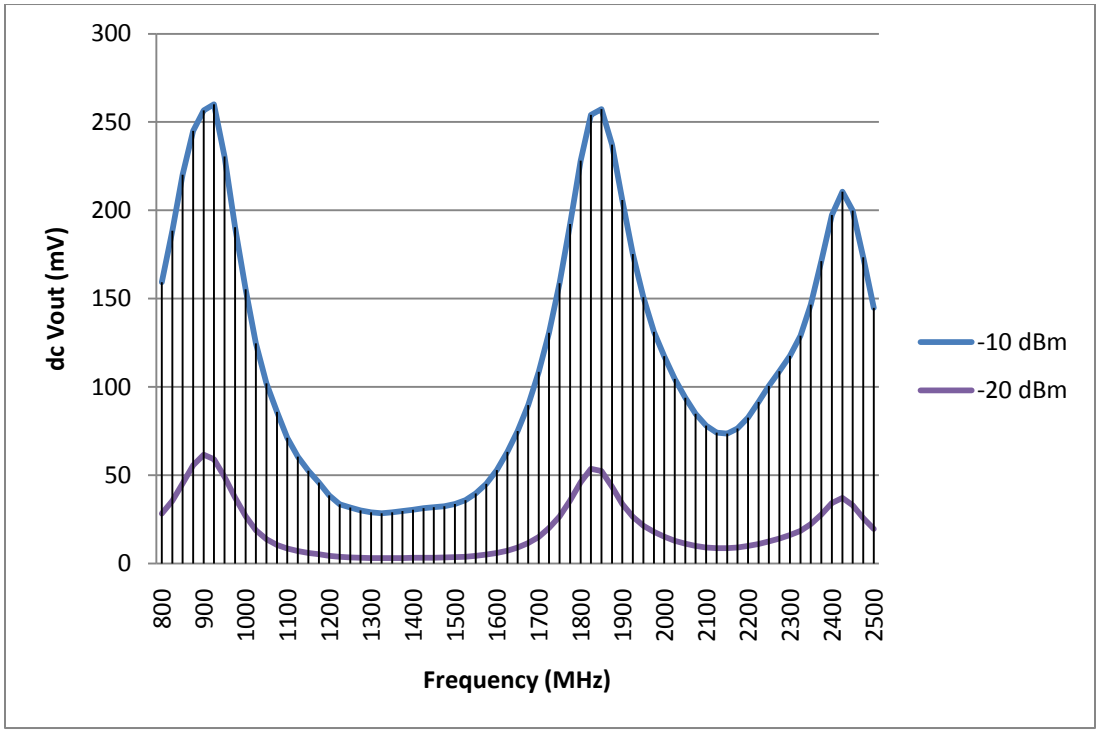

Fig. 4.7.7: Output voltage vs. frequency for -10 and -20 dBm input power

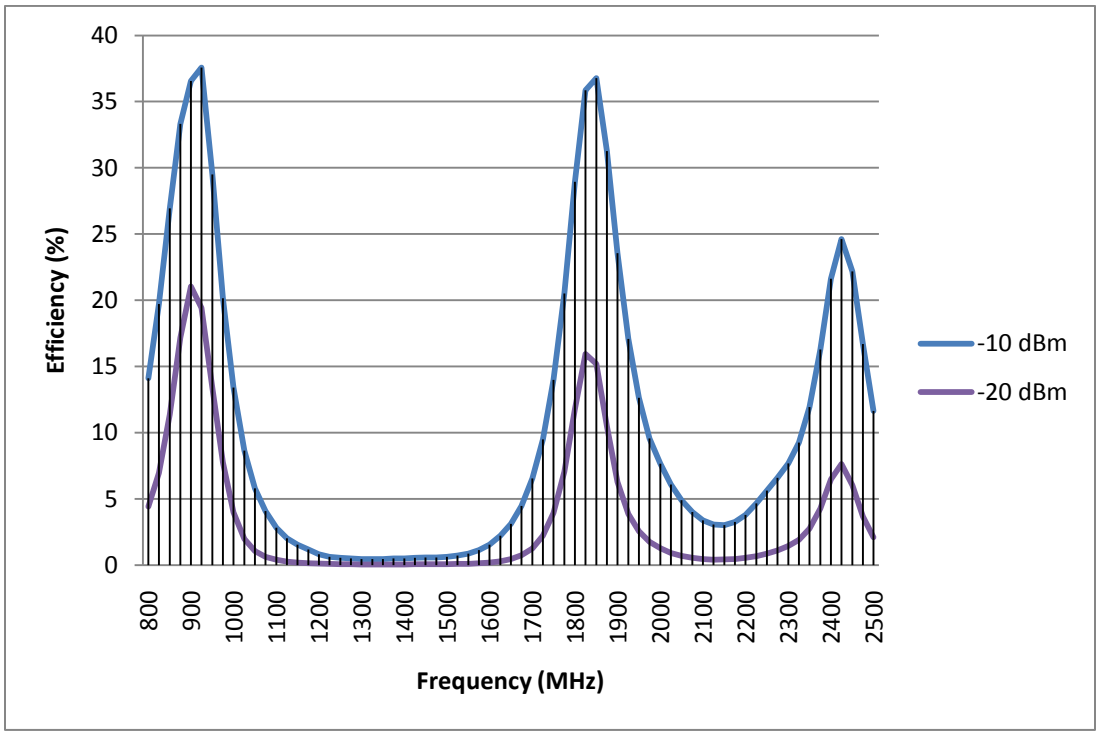

Fig. 4.7.8: Efficiency vs. frequency for -10 and -20 dBm input power

Fig. 4.7.6 shows measurements of the output voltage for a known input power, but now, making a frequency sweep ranging from 800 MHz to 2.5 GHz. The results show a better performance in the frequency bands that are involved in our application for both -10 dBm and -20 dBm input power values. We can conclude it that proper rectifier circuit design and fabrication has been done. A similar behavior is shown in Fig.4.7.7where the efficiency shows a similar pattern to the output voltage. Can be seen that for 900 MHz, 1.85 GHz and 2.45 GHz bands, the efficiency values with -10 dBm input power are around 37%, 36% and 24 % and for -20 dBm input power, the efficiency values are around 21%, 16% and 7% respectively.

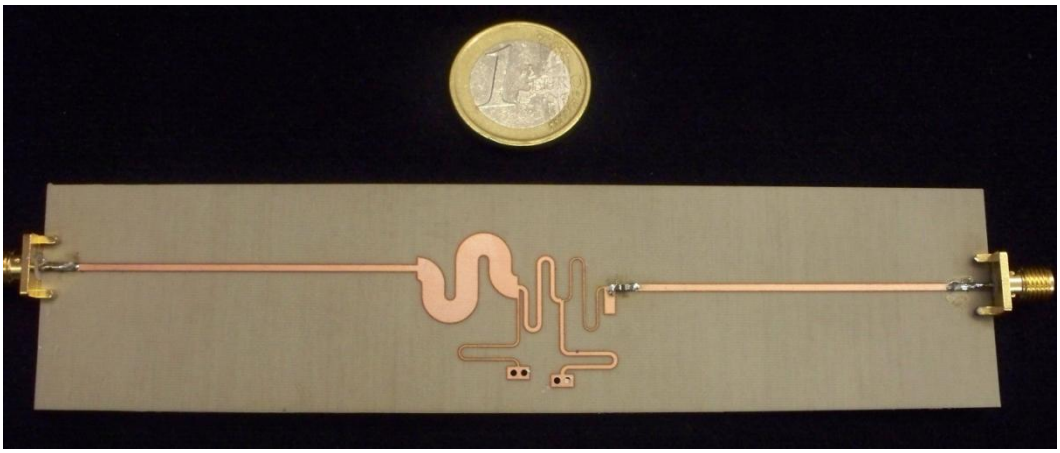

Fig. 4.7.9: matching network

If we compare the measurements results with those of the simulations, we can see that there is a considerable loss of efficiency (especially at the 2.45 GHz band). In order to try to explain this loss, we decided to fabricate and test the matching circuit and check if there is any considerable loss.

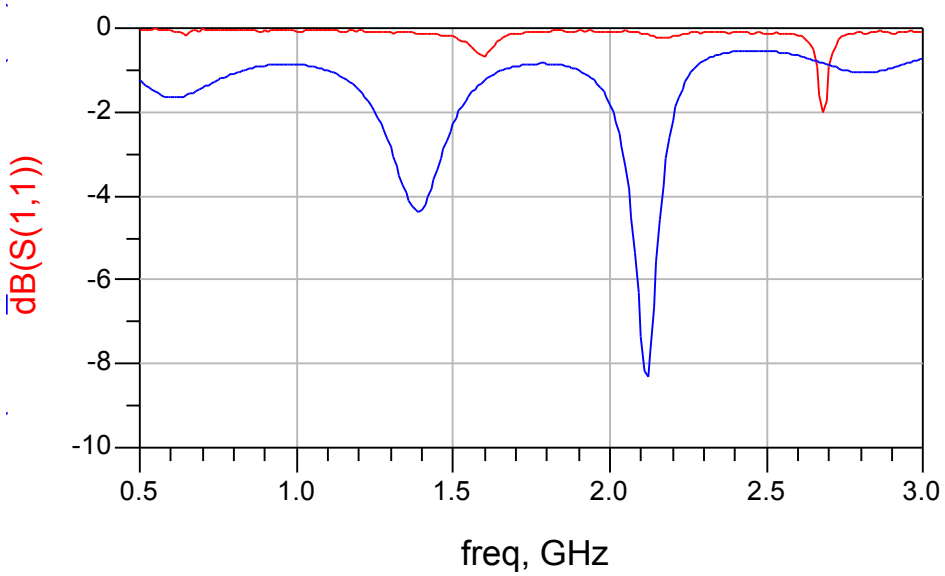

Fig. 4.7.10: S11 comparison: red line = measurement, blue line = simulation

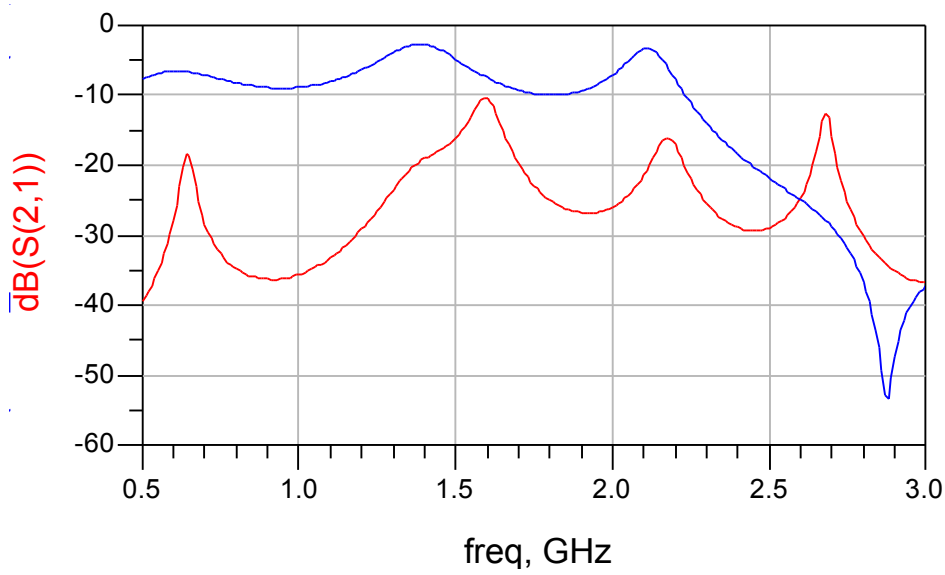

Fig. 4.7.11: S21 comparison: red line = measurement, blue line = simulation

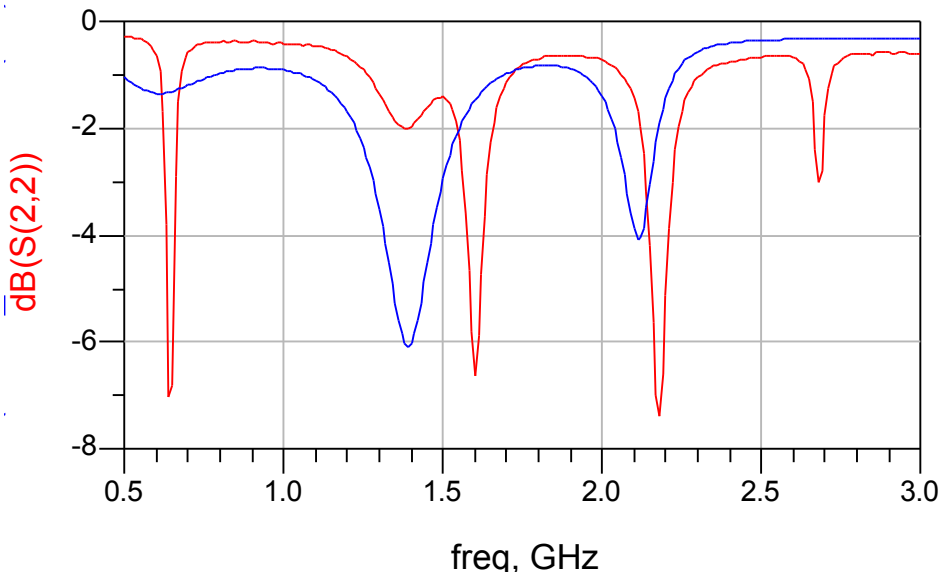

Fig. 4.7.12: S22 comparison: red line = measurement, blue line = simulation

To carry out this measurements a Rohde & Schwarz ZVA24 Vector Network Analyzer (VNA) that, after a SOLT (Short / Open / Load / Thru) calibration for a 500MHz – 3 GHz swept, was used to measure the S-parameters of the circuit. Fig. 4.7.10 – 4.7.11 – 4.7.12, show the results of the measurements.

As we expected, from Figs 4.7.10 and Fig. 4.7.11we can conclude that there is a notable difference that denotes gain loss and high refection coefficients. The reason of this behavior will be an issue of future work that will not be included in this project.

Chapter 5

Future Work and Conclusions

5.1 Future Work

Future work in the energy harvesting field is based on applying these concepts to everyday environments of a person or critical situations, where wireless powering is the only, safe, solution. In this way, it will be feasible to continuously storage energy and perform actions that, until now, conventional methods don not allow making them possible. Some possible new technologies that can be applied to this concept will be briefly described.

5.1.1 Textile Material for Antennas

Textile UWB antennas for WBAN applications have small physical size and can be easily integrated into clothing [22]. Results confirmed the good transient performance over UWB frequencies. As a conductor, high conductive metalized Nylon fabric is commonly used. Its metalized layers provide high conductivity and protection against corrosion, as well as flexibility. As dielectric substrate, acrylic fabric is often used.

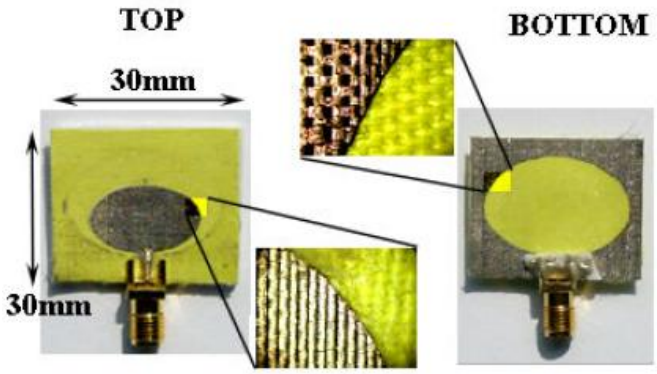

Fig. 5.1.1: textile UWB antenna [22]

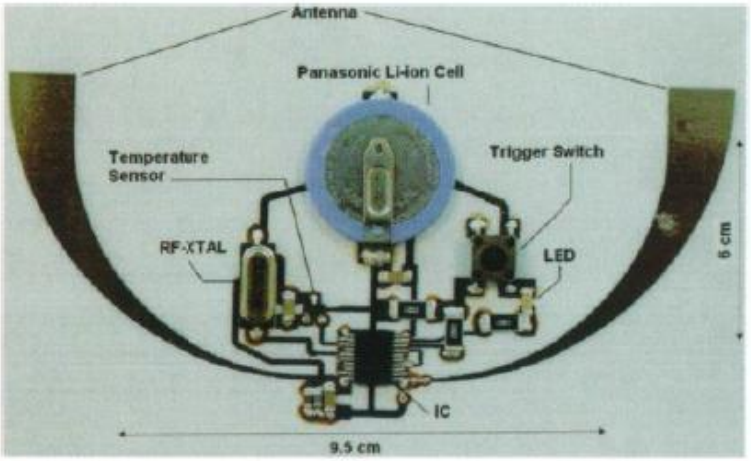

Fig. 5.1.2: wireless-sensor transmitter, on a paper substrate, using silver inkjet-printing technology [23]

5.1.2 Inkjet-Printed Antennas on Flexible Low-Cost Paper-Based Substrates

Paper, which holds one of the biggest market shares in the world, can potentially evolve the electronics market. It could eventually take the first step in creating an environmentally friendly first generation of truly "green" RF electronics and modules.

In addition, paper is one of the lowest-cost materials produced. Inkjet-printing technology (Fig. 5.1.2), which is a much faster and cleaner method than conventional wet-etching techniques that use several chemicals, can serve as a low-cost technology for fabricating RFID tags, produced in large processes on paper

5.1.3 Flexible Antenna on Polyethylene Terephthalate (PET) Substrate

These prototype antennas use low cost, wet deposition techniques to deposit silver and copper onto the substrates.

Fig. 5.1.3: Flexible folded dipole made from electro-less silver deposited on a PET substrate [24]

5.2 Conclusions

Concluded this project, we can affirm that the low power energy harvesting (in the environment) is a widespread trend that is becoming more accepted. For this new kind of "alternative energy" with the use of a rectenna, we conclude that there are still some limitations due mainly to delivered power of a mobile base station or a wireless router, is still low; this power levels can be improved using antennas arrays, or new high efficiency rectifiers. On the other hand, this energy can be stored, having as analogous application the solar energy, where sometimes photo voltaic modules are used to charge batteries that, subsequently, will supply power to other devices. We can also conclude that the use of this technology, for everyday applications, is being investigated, as well as cheaper and more flexibility material are being increasingly used at the time of the design of these applications.

Is also concluded that incident power densities, for both GSM-1900 and GSM-1800, are practically in the same order of magnitude, and that the incident power density of the ISM 2.4 GHz band, although the wireless router is closer than a mobile base station, is one order of magnitude below. We also conclude that for both, GSM and WLAN networks, the incident power density depends on the traffic at the time of measurement.

Respect to the antenna, it is concluded that the dimensions can be reduced by analyzing the current distribution on the surface of the conductors, moreover, that non-symmetrical cuts, can modify the radiation pattern of the antenna.

With respect to the rectifier, it is concluded that the use of microstrip lines for the matching circuit design, contributed to a lower soldering loss than if components, such as inductors and capacitors, were used.

Chapter 1

Radio Principles

Communications and information systems (CIS) are any systems whose primary functions are to collect, process, or exchange information. The fundamental requirement is to provide the Marine air-ground task force (MAGTF) commander with a reliable, secure, fast, and flexible communications network.

Communications and information systems automate routine functions, thereby freeing commanders and staffs to focus on those aspects of command and control that require experience, judgment, and intuition.

These systems and the personnel who install, operate, and maintain them play a key role in the command and control of the MAGTF. Communications and informations systems support the commander and every staff section in every phase of operations planning and execution.

These systems facilitate information flow throughout the MAGTF and provide shared situational awareness, informed decisionmaking, and rapid dissemination of decisions.

The success of the MAGTF in the modern battlespace depends on the effective employment of communications and information systems. Single-channel radio (SCR) is one of the most important components of MAGTF CIS.

Section I. Theory and Propagation

BASIC COMPONENTS OF RADIO EQUIPMENT

The radio equipment for communication between two stations and the path the signal follows through the air is called a radio link. A radio link consists of seven components: the transmitter, power supply, transmission lines, transmitting antenna, propagation path, receiving antenna, and receiver (see figure 1-1).

The transmitter generates a radio signal. The power supply (i.e., battery or generator) supplies power for the operating voltage of the radio. The transmission line delivers the signal from the transmitter to the antenna.

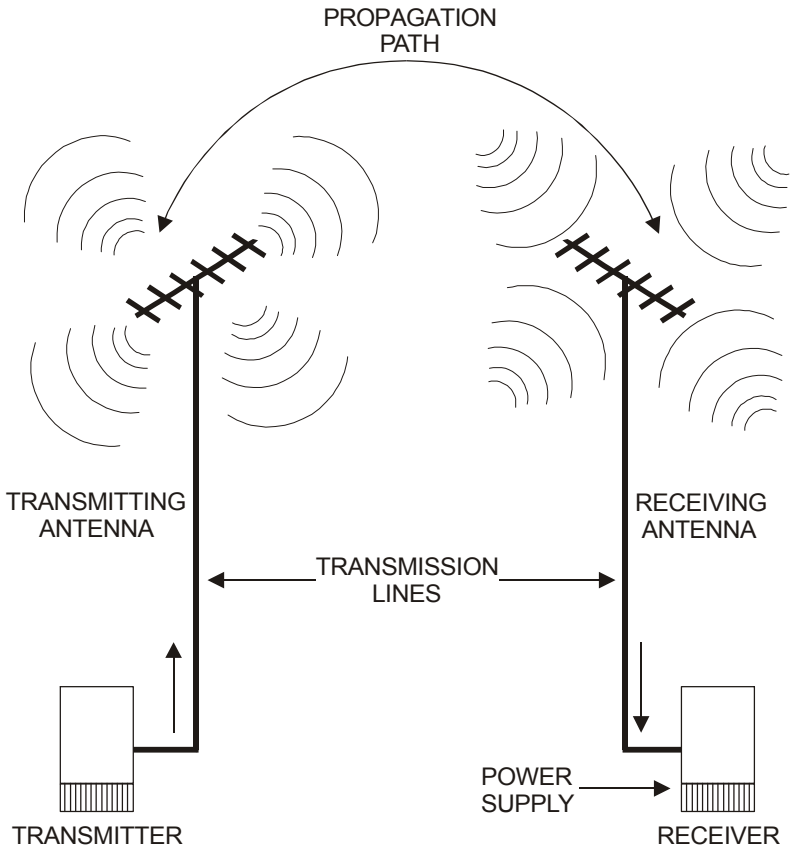

Figure 1-1. Radio Link.

The transmitting antenna sends the radio signal into space toward the receiving antenna. The path in space that the radio signal follows as it goes to the receiving antenna is the propagation path. The receiving antenna intercepts or receives the signal and sends it through a transmission line to the receiver. The receiver processes the radio signal so the human ear can hear it.

When transmitting, the radio operator aims to provide the strongest possible signal at the site of the receiving station. The best possible signal is that signal which will provide the greatest signal-to-noise ratio at the receiving antenna.

To transmit the best possible signal, select or determine the—

- Optimum frequency.
- Best antenna for that frequency based on the available space of the transmitting site.
- Proper propagation path.

RADIO WAVES

Propagation Velocity (Speed)

Radio waves travel near the surface of the Earth and radiate skyward at various angles to the Earth's surface. These electromagnetic waves travel through space at the speed of light, approximately 300,000 kilometers (km) or 186,000 miles (mi) per second.

Wavelength

Wavelength is the distance between the crest of one wave and the crest of the next wave (see figure 1-2 on page 1-4). It can also be the length of one complete cycle of the waveform. It is also the distance traveled during one complete cycle. The length of the wave is always measured in meters.

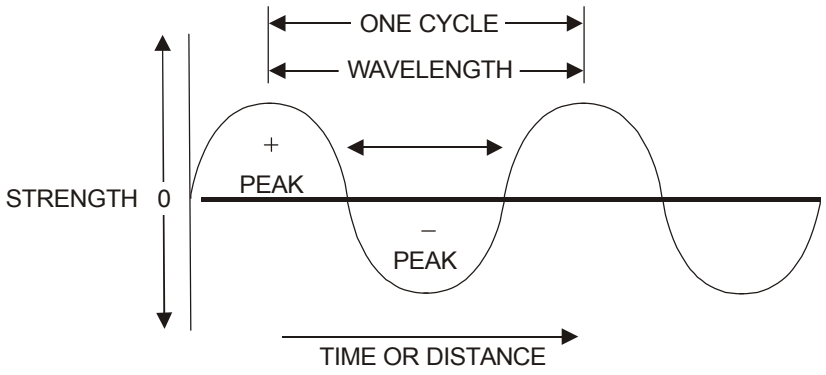

Figure 1-2. Radio Waves.

Radio Frequency

The frequency of a radio wave is the number of complete cycles that occur in one second. The longer the cycle, the longer the wavelength and the lower the frequency. The shorter the cycle, the shorter the wavelength and the higher the frequency. Frequency is measured and stated in units called hertz (Hz). One cycle per second is stated as 1 hertz. Because the frequency of a radio wave is very high, it is generally measured and stated in thousands of hertz (kilohertz [KHz]) or in millions of hertz (megahertz [MHz]). One KHz is equal to 1,000 cycles per second, and 1 MHz is equal to a million cycles per second. Sometimes frequencies are expressed in billions of hertz (gigahertz [GHz]). One GHz is equal to a billion cycles per second.

For practical purposes, the velocity of a radio wave is considered to be constant, regardless of the frequency or the amplitude of the transmitted wave. Therefore, to find the frequency when the wavelength is known, divide the velocity by the wavelength.

$$\text{Frequency (hertz)} = \frac{\text{300 million (meters per second)}}{\text{Wavelength (meters)}}$$

To find the wavelength when the frequency is known, divide the velocity by the frequency.

$$\text{Wavelength (meters)} = \frac{\text{300 million (meters per second)}}{\text{Frequency (hertz)}}$$

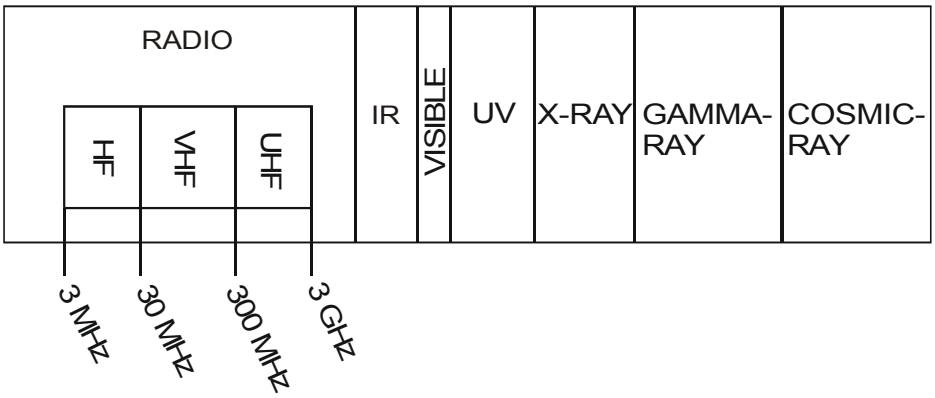

Figure 1-3. Electromagnetic Spectrum.

Within the radio frequency spectrum (see figure 1-3), radio frequencies are divided into groups or bands of frequencies. The radio frequency spectrum is part of the electromagnetic spectrum. Most tactical radio sets operate within a 2- to 400-MHz range within the frequency spectrum.

Each frequency band has certain characteristics. The ranges and power requirements shown in table 1-1 are for normal operating conditions (proper siting and antenna orientation and correct operating procedures). The ranges will change according to the condition of the propagation medium and the transmitter output power.

Table 1-1. Frequency Range Characteristics.

Band	Ground Wave Range	Sky Wave Range	Power Required
HF	0-50 miles	100-8000 miles	.5-5 kW
VHF	0-30 miles	50-150 miles	.5 or less kW
UHF	0-50 miles	N/A	.5 or less kW

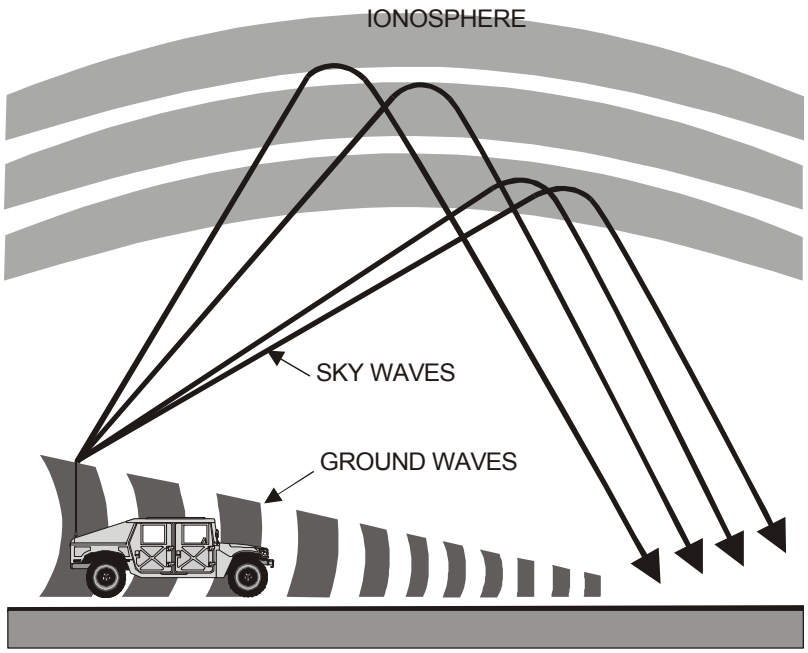

Figure 1-4. Principle Paths of Radio Waves.

RADIO WAVE PROPAGATION

There are two principal paths by which radio waves travel from a transmitter to the receiver (See figure 1-4): ground wave—which travels directly from the transmitter to the receiver and sky wave—which travels up to the ionosphere and is refracted (i.e., bent downward) back to the Earth. Short-distance, ultrahigh frequency (UHF), and upper very high frequency (VHF) transmissions are by ground waves. Long-distance, high frequency (HF) transmission is principally by sky waves. Single-channel radio sets can use ground wave or sky wave propagation for communications.

Ground Wave Propagation

Radio communications which use ground wave propagation do not use or depend on waves that are refracted from the ionosphere (i.e., sky waves). Ground wave propagation is affected by the electrical characteristics of the Earth and by the amount of diffraction (i.e., bending) of the

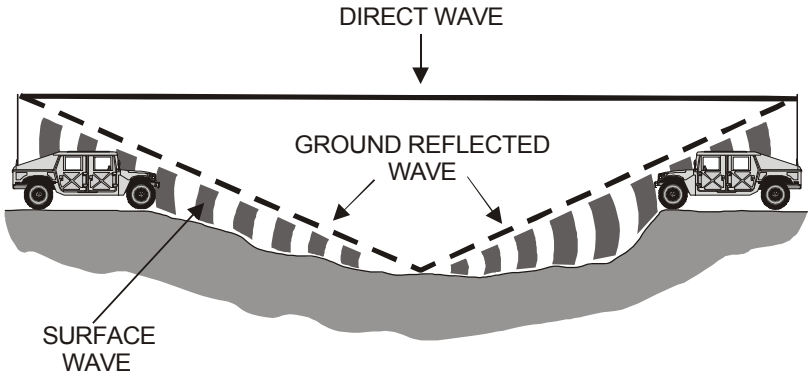

Figure 1-5. Ground Wave Propagation.

waves along the curvature of the Earth. The strength of the ground wave at the receiver depends on the power output and frequency of the transmitter, the shape and conductivity of Earth along the transmission path, and the local weather. The following paragraphs describe the components of a ground wave. See figure 1-5.

Direct Wave. The direct wave is that part of the radio wave which travels directly from the transmitting antenna to the receiving antenna. This part of the wave is limited to the line of sight (LOS) distance between the transmitting and receiving antennas, plus the small distance added by atmospheric refraction and diffraction of the wave around the curvature of the Earth. This distance can be extended by increasing the height of the transmitting antenna, the receiving antenna, or both.

Ground Reflected Wave. The ground reflected wave is that portion of the radio wave which reaches the receiving antenna after being reflected from the surface of the earth. Cancellation of the radio signal can occur when the ground reflected component and the direct wave component arrive at the receiving antenna at the same time and are 180° out of phase with each other.

Surface Wave. The surface wave, which follows the curvature of the Earth, is that part of the ground wave which is affected by the conductivity and dielectric constant of the Earth.

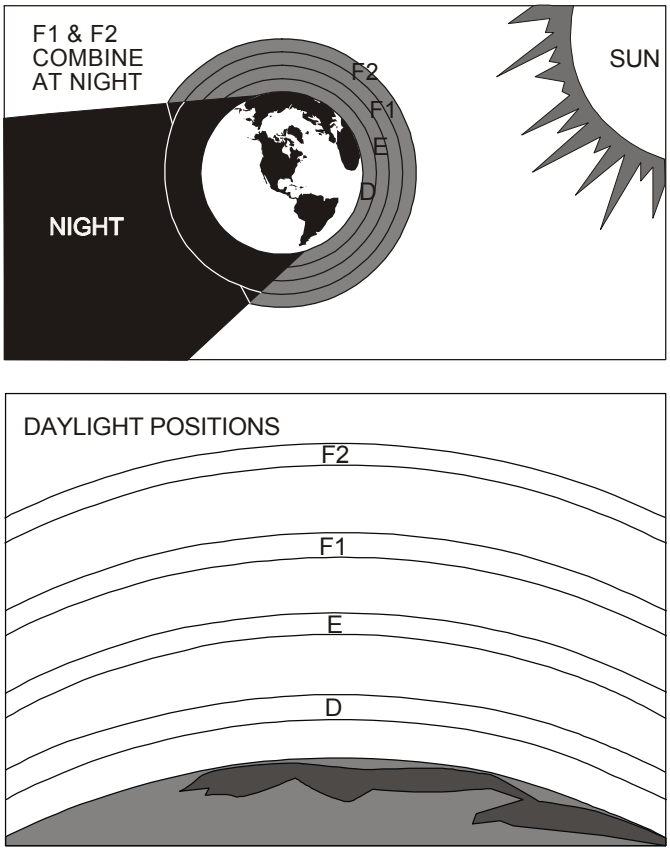

Figure 1-6. Layers of the Ionosphere.

Sky Wave Propagation

Radio communications that use sky wave propagation depend on the ionosphere to provide the signal path between the transmitting and receiving antennas.

Ionospheric Structure. The ionosphere has four layers (see fig. 1-6). In order of increasing heights and decreasing molecular densities, these layers are labeled D, E, F1, and F2. During the day, when the rays of the

Sun are directed toward that portion of the atmosphere, all four layers may be present. At night, the F1 and F2 layers seem to merge into a single F layer, and the D and E layers fade out. The actual number of layers, their height above the Earth, and their relative intensity of ionization varies constantly. The following are layers of the ionosphere:

- D—exists only during daylight hours and has little effect in bending the paths of high frequency radio waves. The main effect of the D layer is to attenuate high frequency waves when the transmission path is in sunlit regions.
- E—used during the day for high frequency radio transmission over intermediate distances (less than 2,400 km [1,500 mi]). At night, the intensity of the E layer decreases, and it becomes useless for radio transmission.
- F—exists at heights up to 380 kilometers (240 mi) above the Earth and is ionized all the time. It has two well-defined layers (F1 and F2) during the day, and one layer (i.e., F) during the night. At night, the F layer remains at a height of about 260 kilometers (170 mi) and is useful for long-range radio communications (over 2,400 km [1,500 mi]). The F2 layer is the most useful of all layers for long-range radio communications, even though its degree of ionization varies appreciably from day to day.

Factors Affecting the Ionosphere. The movements of the Earth around the Sun and changes in the Sun's activity contribute to ionospheric variations. There are two main classes of variations: regular, which is predictable; and irregular, which occurs from abnormal behavior of the Sun.

Regular Variations of the Ionosphere. The regular variations are—

- Daily—caused by the rotation of the Earth.
- Seasonal—caused by the north and south progression of the Sun.
- 27-day—caused by the rotation of the Sun on its axis.
- 11-year—caused by the sunspot activity cycle going from maximum to minimum, back to maximum levels of intensity.

Irregular Variations of the Ionosphere. The current status of the four regular variations must be anticipated when planning a communications system. There are also unpredictable, irregular variations that must be considered. They have a degrading effect (at times blocking communications) which cannot be controlled or compensated for at present. Some irregular variations are—

- Sporadic E. When it is excessively ionized, the E layer often blocks out the reflections back from the higher layers. It can also cause unexpected propagation of signals hundreds of miles beyond the normal range. This effect can occur at any time.
- Sudden ionospheric disturbance (SID). A sudden ionospheric disturbance coincides with a bright solar eruption and causes abnormal ionization of the D layer. This effect causes total absorption of all frequencies above approximately 1 MHz. It can occur without warning during daylight hours and last from a few minutes to several hours. When SID occurs, receivers seem to go dead.
- Ionospheric storms. During these storms, sky wave reception above approximately 1.5 MHz shows low intensity and is subject to a type of rapid blasting and fading called "flutter fading." These storms may last from several hours to days and usually extend over the entire Earth.

Sunspots. Sunspots generate bursts of radiation that cause high levels of ionization. The more sunspots, the greater the ionization. During periods of low sunspot activity, frequencies above 20 MHz tend to be unusable because the E and F layers are too weakly ionized to reflect signals back to earth. At the peak of the sunspot cycle, however, it is not unusual to have worldwide propagation on frequencies above 30 MHz.

Frequency Characteristics in the Ionosphere. The range of long-distance radio transmission is determined primarily by the ionization density of each layer. The higher the frequency, the greater the ionization density required to reflect radio waves back to Earth. The upper (i.e., E and F) layers reflect the higher frequencies because they are the most highly ionized. The D layer, which is the least ionized, does not reflect frequencies above approximately 500 KHz. Thus, at any given time and for each

ionized layer, there is an upper frequency limit at which radio waves sent vertically upward are reflected back to Earth. This limit is called the critical frequency.

Radio waves directed vertically at frequencies higher than the critical frequency pass through the ionized layer out into space. All radio waves directed vertically into the ionosphere at frequencies lower than the critical frequency are reflected back to Earth. Radio waves used in communications are generally directed towards the ionosphere at some oblique angle, called the angle of incidence. Radio waves at frequencies above the critical frequency will be reflected back to Earth if transmitted at angles of incidence smaller than a certain angle, called the critical angle. At the critical angle and all angles larger than the critical angle the radio waves will pass through the ionosphere if the frequency is higher than the critical frequency. When the angle of transmission becomes smaller, the radio waves will be reflected back to Earth.

Transmission Paths. The distance from the transmitting antenna to the place where the sky waves first return to Earth is called the skip distance. The skip distance is dependent on the angle of incidence, the operating frequency, and the height and density of the ionosphere. The antenna height, in relation to the operating frequency, affects the angle that transmitted radio waves strike and penetrate the ionosphere and then return to Earth. This angle of incidence can be controlled to obtain the desired area of coverage. Lowering the antenna will increase the angle of transmission and provide broad and even signal patterns in a large area. The use of near-vertical transmission paths is known as near-vertical incidence sky wave (NVIS). Raising the antenna will lower the angle of incidence. Lowering the angle of incidence can produce a skip zone in which no usable signal can be received. This area is bounded by the outer edge of usable ground wave propagation and the point nearest the antenna at which the sky wave returns to Earth. In most communications situations, the skip zone is not a desirable condition. However, low angles of incidence make long-distance communications possible.

When a transmitted wave is reflected back to the surface of the Earth, part of its energy is absorbed by the Earth. The remainder of its energy is reflected back into the ionosphere to be reflected back again. This means

of transmission—by alternately reflecting the radio wave between the ionosphere and the Earth—is called hops, and it enables radio waves to be received at great distances from the point of origin.

Maximum Usable and Lowest Usable Frequencies. There is a maximum frequency at which a radio wave will return to Earth at a given distance when a given ionized layer and a transmitting antenna with a fixed angle of radiation is used. This frequency is called the maximum usable frequency (MUF). It is the monthly median of the daily highest frequency that is predicted for sky wave transmission over a particular path at a particular hour of the day. The MUF is always higher than the critical frequency because the angle of incidence is less than 90°. If the distance between the transmitter and the receiver is increased, the maximum usable frequency will also increase. Radio waves lose some of their energy through absorption by the D layer and the portion of the E layer of the ionosphere at certain transmission frequencies.

The total absorption is less and communications are more satisfactory as higher frequencies are used up to the level of the MUF. The absorption rate is greatest for frequencies ranging from approximately 500 KHz to 2 MHz during the day. At night, the absorption rate decreases for all frequencies. As the frequency of transmission over any sky wave path is decreased from high to low frequencies, a frequency will be reached at which the received signal just overrides the level of atmospheric and other radio noise interference. This is called the lowest useful frequency (LUF) because frequencies lower than the LUF are too weak for useful communications. The LUF also depends on the power output of the transmitter as well as the transmission distance. When the LUF is greater than the MUF, no sky wave transmission is possible.

Section II. Modulation and Single Side Band Transmission

Radio communications equipment is used primarily to transmit voice and data. Although sound can be converted to audio frequency electrical energy, it is not practical to transmit it in this energy form through the Earth's atmosphere by electromagnetic radiation. For example, efficient transmission of a 20-hertz audio signal would require an antenna almost 8,000 kilometers (5,000 mi) long. This would not apply when radio frequency electrical energy is used to carry the intelligence. When radio frequency electrical energy is used, great distances can be covered; efficient antennas for radio frequencies are of practical lengths; and antenna power losses are at reasonable levels.

The frequency of the radio wave affects its propagation characteristics. In the low frequency band (.03 to.3 MHz), the ground wave is very useful for communications over great distances. The ground wave signals are quite stable and show little seasonal variation. In the medium frequency band (.3 to 3.0 MHz), the range of the ground wave varies from about 24 kilometers (15 mi) at 3 MHz, to about 640 kilometers (400 mi) at the lowest frequencies of this band. Sky wave reception is possible during the day or night at any of the lower frequencies in this band. At night, the sky wave is receivable at distances up to 12,870 kilometers (8,000 mi). In the high frequency band (3 to 30 MHz), the range of the ground wave decreases as frequency increases, and the sky waves are greatly influenced by ionospheric considerations.

In the very high frequency band (30 to 300 MHz), there is no usable ground wave and only slight refraction of sky waves by the ionosphere at the lower frequencies. The direct wave provides communications if the transmitting and receiving antennas are elevated high enough above the surface of the Earth.

In the ultrahigh frequency band (300 to 3,000 MHz), the direct wave must be used for all transmissions. Communications are limited to a short distance beyond the horizon. Lack of static and fading in these bands makes line of sight reception very satisfactory. Antennas that are highly directional can be used to concentrate the beam of radio frequency (RF) energy, thus, increasing the signal intensity.

MODULATION

Both amplitude modulation (AM) and frequency modulation (FM) transmitters produce RF carriers. The carrier is a wave of constant amplitude, frequency, and phase which can be modulated by changing its amplitude, frequency, or phase. Thus, the RF carrier "carries" intelligence by being modulated. Modulation is the process of superimposing intelligence (voice or coded signals) on the carrier.

Amplitude Modulation

Amplitude modulation is the variation of the RF power output of a transmitter at an audio rate. In other words, the RF energy increases and decreases in power according to the audio frequencies superimposed on the carrier signal.

When audio frequency signals are superimposed on the radio frequency carrier signal, additional RF signals are generated. These additional frequencies are equal to the sum of, and the difference between the audio frequencies and the radio frequency used. For example, assume a 500-KHz carrier is modulated by a 1-KHz audio tone. Two new frequencies are developed, one at 501 KHz (the sum of 500 KHz and 1 KHz) and the other at 499 KHz (the difference between 500 KHz and 1 KHz). If a complex audio signal is used instead of a single tone, two new frequencies will be set up for each of the audio frequencies involved. The new frequencies resulting from superimposing an audio frequency (AF) signal on an RF signal are called side bands.

When the RF carrier is modulated by complex tones such as speech, each separate frequency component of the modulating signal produces its own upper and lower side band frequencies. The side band that contains the sum of the RF and AF signals is called the upper side band. The side band that contains the difference between the RF and AF signals is called the lower side band.

The space occupied by a carrier and its associated side bands in the radio frequency spectrum is called a channel. In amplitude modulation, the width of the channel (bandwidth) is equal to twice the highest

modulating frequency. For example, if a 5,000 KHz (5 MHz) carrier is modulated by a band of frequencies ranging from 200 to 5,000 cycles (.2 to 5 KHz), the upper side band extends from 5,000.2 to 5,005 KHz. The lower side band extends from 4,999.8 KHz to 4,995 KHz. Thus, the bandwidth is the difference between 5,005 KHz and 4,995 KHz, a total of 10 KHz.

Frequency Modulation

Frequency modulation is the process of varying the frequency (rather than the amplitude) of the carrier signal in accordance with the variations of the modulating signals. The amplitude or power of the FM carrier does not vary during modulation.

The frequency of the carrier signal when it is not modulated is called the center or rest frequency. When a modulating signal is applied to the carrier, the carrier signal will move up and down in frequency, away from the center or rest frequency.

The amplitude of the modulating signal determines how far away from the center frequency the carrier will move. This movement of the carrier is called deviation; how far the carrier moves is called the amount of deviation. During reception of the FM signal, the amount of deviation determines the loudness or volume of the signal.

The FM signal leaving the transmitting antenna is constant in amplitude but varies in frequency according to the audio signal. As the signal travels to the receiving antenna, it picks up natural and man-made electrical noises that cause amplitude variations in the signal. All of these undesirable amplitude variations are amplified as the signal passes through successive stages of the receiver until the signal reaches a part of the receiver called the limiter. The limiter is unique to FM receivers as is the discriminator.

The limiter eliminates the amplitude variations in the signal, then passes it on to the discriminator which is sensitive to variations in the frequency of the RF wave. The resultant constant amplitude, frequency-modulated signal is then processed by the discriminator circuit which changes the

frequency variations into corresponding voltage amplitude variations. These voltage variations reproduce the original modulating signal in a headset, loudspeaker, or teletypewriter. Frequency modulation is generally used by radiotelephone transmitters operating in the VHF and higher frequency bands.

SINGLE SIDE BAND TRANSMISSION

The intelligence of an AM signal is contained solely in the side bands. Each side band contains all the intelligence needed for communications. Therefore, one side band and the carrier signal can be eliminated. This is the principle on which single side band (SSB) communications is based. Although both side bands are generated within the modulation circuitry of the SSB radio set, the carrier and one side band are removed before any signal is transmitted.

The side band that is higher in frequency than the carrier is called the upper side band (USB). The side band that is lower in frequency than the carrier is called the lower side band (LSB). Either side band can be used for communications as long as both the transmitter and the receiver are adjusted to the same side band. Most SSB equipment operates in the USB mode. The transmission of only one side band leaves open that portion of the RF spectrum normally occupied by the other side band of an AM signal. This allows more emitters to be used within a given frequency range.

Single side band transmission is used in applications when it is desired to—

- Obtain greater reliability.
- Limit size and weight of equipment.
- Increase effective output without increasing antenna voltage.
- Operate a large number of radio sets without heterodyne interference (e.g., whistles and squeals) from radio frequency carriers.
- Operate over long ranges without loss of intelligibility because of selective fading.

Chapter 2

Single-Channel Radio

SINGLE-CHANNEL RADIO COMMUNICATIONS EQUIPMENT

Single-channel radio is the principal means of communications support for MAGTF maneuver units. SCR communications equipment is easy to operate. The networks are easily established, rapidly reconfigured, and, most importantly, easily maintained on the move. SCR provides secure voice communications and supports limited data information exchange. SCR in the VHF and UHF bands is normally limited to line of sight. In the HF band, SCR can support long-range communications. SCR satellite communications (SATCOM) provides mobility, flexibility, and ease of operation with unlimited range. Limitations of SCR include susceptibility to enemy electronic warfare (i.e., cosite, terrain, and atmospheric interference); the requirement for close coordination and detailed planning (i.e., a need for common timing, frequency, and equipment); and limited spectrum availability. The latter is particularly critical in the case of SATCOM.

MAGTF SCR equipment is fielded in many configurations and includes hand-held, manpack, vehicle-mounted, bench-mounted, and sheltered radios. These radios operate in simplex and half-duplex modes. The most widely employed tactical radios provide integrated communications security (COMSEC) and jam resistance through frequency hopping. Tactical SCRs operate in the three military radio frequency bands shown in Table 2-1 on page 1-2.

Table 2-1. SCR Equipment.

Frequency Band	MAGTF SCR Equipment Used	Operating Frequency Range	Typical Application
HF	AN/PRC-104 AN/GRC-193 AN/MRC-138 AN/TSC-120	2-29.999 MHz	Radio line of sight and beyond/long range
VHF	AN/VRC-12 family: AN/PRC-68 AN/PRC-77 SINCGARS family: AN/PRC-119 AN/VRC-88 (A, D) AN/VRC-89 (A, D) AN/VRC-90 (A, D) AN/VRC-91 (A, D) AN/VRC-92 (A, D) AN/GRC-213 AN/MRC-145	30-88 MHz	Radio line of sight and relay/retrans-mission
	AN/PRC-113 AN/VRC-83	116-150 MHz	Critical line of sight (ground to air)
UHF	AN/PRC-113 AN/VRC-83 AN/GRC-171	225-400 MHz	Critical line of sight (ground to air)
	AN/PSC-3 AN/PSC-5		SATCOM footprint

HIGH FREQUENCY RADIO

HF radio equipment is capable of both long- and short-range secure voice and data communications. Data communications capability is typically limited to rates of 2.4 kilobits per second (kbps). Data transmission requires modems specifically designed for operation in this band of the radio spectrum. The AN/PRC-104 is capable of remote operation by using the analog AN/GRA-39B radio remote control. See fig. 2-1.

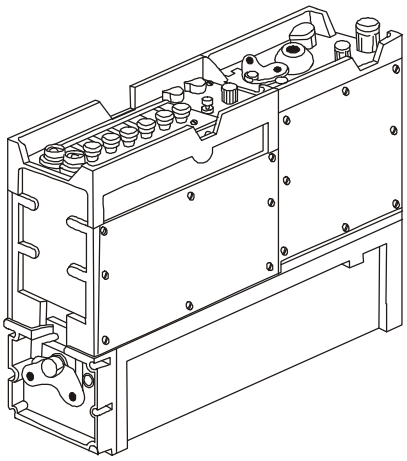

Figure 2-1. AN/PRC-104 HF Radio.

High frequency communications are capable of traveling around the world under the right conditions. This accounts for the large number of signals and noise in the receiver (e.g., thunderstorms). Conversely, the HF transmission may be intercepted and traced by the enemy who is many hundreds of miles away. VHF and UHF communications are normally limited to line of sight; therefore, their range is restricted. UHF transmissions may also be used in satellite communications, increasing ranges to thousands of miles.

High Frequency Radio Employment Considerations.

The primary advantage of using HF radio is its capability to provide long-range, over the horizon (OTH) communication. Successful data communications over the HF range depends on several factors: equipment siting, proper equipment grounding, types of antennas used, and other considerations such as tactical employment of radio equipment, path assessment and analysis, and frequency planning and assignment. When commercial data terminal equipment (DTE) is used, users employing HF radio equipment need to be aware of radio interference and potential shock hazards that can easily affect unprotected DTE. Whenever possible, HF radio equipment should be remoted from DTE.

High Frequency Radio Environmental Limitations

The primary limiting factors when using HF radios are frequency allocation and management and bandwidth availability. Frequency allocation and management is concerned with frequency, time of day, time of year, and location. The ability to reflect HF radio waves off the ionosphere to a distant location is in a constant state of flux because of activity in the ionosphere. The Sun's radiation causes disturbances in the ionosphere, with most changes taking place in what is known as the F layer (see chapter 1 for more details). Sunrise and sunset can be the most difficult times for HF communications. The F layer splits into two separate layers around sunrise and recombines into one layer around sunset. These splits affect transmission distances as the area "skipped over" increases and decreases. At times, solar storms can eliminate all HF communications. HF transmission paths must be constantly monitored to achieve a dependable HF link. HF radio data communications capabilities are limited by the bandwidth that is imposed by legal constraints and the physics of the spectrum. The bandwidth available in the HF spectrum limits the channel bandwidth, which limits data throughput.

High Frequency Propagation

There are two modes of propagation in HF: ground wave and sky wave. See figure 2-2.

Ground Wave. Ground wave propagation involves the transmission of a signal along the surface of the ground. The maximum ground wave range for most tactical HF communications is about 20 to 30 kilometers (12 to 22 miles) for manpack equipment and 80 to 100 kilometers for high-power vehicular and van equipment. The range may be decreased by heavy vegetation (e.g., Camp Lejeune), mountainous terrain (e.g., Camp Pendleton), or dry desert soil (e.g., Twenty-nine Palms). A ground wave circuit will generally be free of fading and may last for the entire 24-hour period without the need to change frequencies.

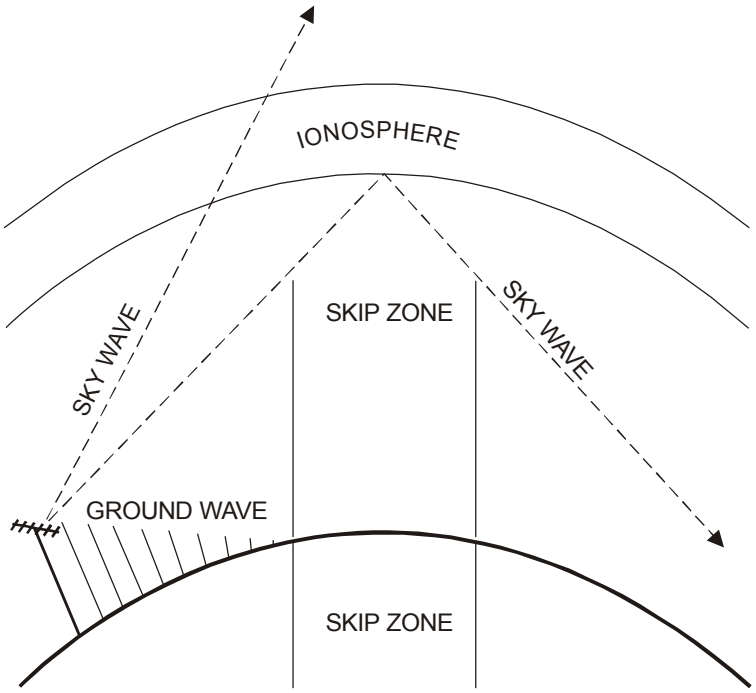

Figure 2-2. HF Propagation.

Sky Wave. Beyond this range, it is necessary to communicate by sky wave. Sky wave propagation involves the bending of the signal by the ionosphere. Frequencies are very important, as those above a certain value will not bend back to earth but will punch through the ionosphere into outer space. On the other hand, lower frequencies are noisier and become absorbed by the ionosphere. The reflective nature of the ionosphere will change when sunlight hits it each day. As a result, at least two frequencies are usually required during a 24-hour period: a low, night frequency and a higher, day frequency.

Skip Zone

A skip zone is where no signals will be received from a particular transmitter for a particular frequency. Skip zones are formed when the nearest point at which a sky wave is received is beyond the furthest point at which a ground wave is received. By using an antenna with a high

radiation take-off angle (i.e., the angle measured from the Earth's surface to horizon up to the direction of propagation towards the ionosphere), HF radio waves can be bounced off the ionosphere and come back to earth closer than they can with more commonly used antennas. This can cause the skip zone to disappear if the waves do not punch through.

The use of high radiation take-off angles is called near-vertical incident sky wave (NVIS) communications. The limit of the effective range of NVIS communications is usually about 300 miles. NVIS communications require a horizontally polarized antenna and are done over frequencies between 2 and 12 MHz. Launch angles can be changed by altering the antenna's height above ground, but for most tactical applications one-quarter wavelength above ground is sufficient. NVIS communications are particularly useful because they can be transmitted from moving vehicles. Used correctly, NVIS provides reliable, continuous communications beyond the range of HF ground wave and VHF and UHF line of sight. Multipath interference occurs when both the sky wave and the ground wave signals from the transmitter arrive at different times at the receiver. See figure 2-3. More detailed information on HF propagation and antennas may be found in MCRP 6-22D, *Antenna Handbook*.

VERY HIGH FREQUENCY RADIO

The primary MAGTF VHF radio is the single-channel ground and airborne radio system (SINCGARS). SINCGARS is a family of lightweight combat radios that serves as the primary means of communications for command and control and fire support on the battlefield. SINCGARS is the standard VHF-FM tactical radio for the Marine Corps, replacing the AN/PRC-77 and the AN/VRC-12 family. The system provides high security against threat electronic warfare (EW) by using frequency hopping with integrated COMSEC. It is capable of voice and data transmission (up to 16 kbps under optimum conditions and over limited distances) over the VHF-FM frequency range of 30 to 87.975 MHz. See MCRP 6-22A, *Talk II SINCGARS Multiservice Communications Procedures for the Single-Channel Ground and Airborne Radio System*, for more details.

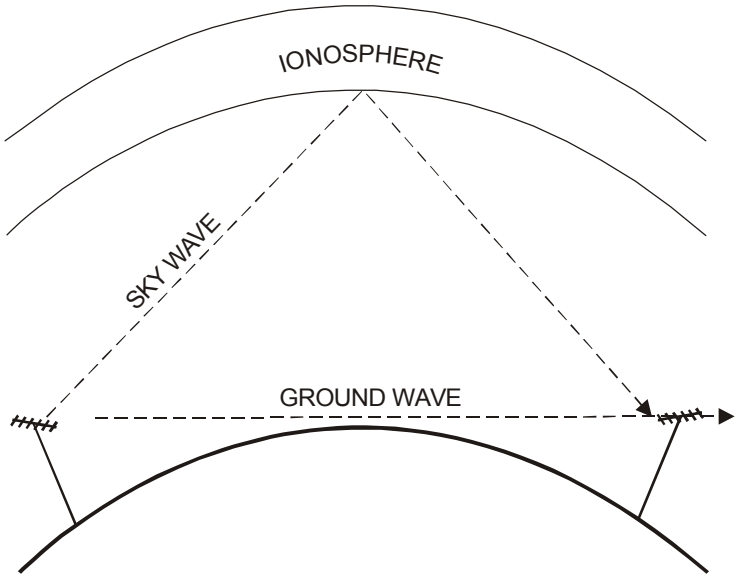

Figure 2-3. Multipath Interference.

There are seven different SINCGARS configurations available, depending on the requirements of the user. These configurations include the manpack AN/PRC-119 (see figure 2-4 on page 2-8), typically used in infantry operations, and vehicle-mounted variants. The radio provides voice communications ranges of up to 8 km for the manpack and 35 km for vehicular configurations. SINCGARS is capable of remote operation by using the analog AN/GRA-39B radio remote control, the digital HYX-57 wire-line ADAPTER, or the digital C-11561 (C)/U remote control unit (RCU).

The SINCGARS radio has undergone a systems improvement program (SIP). This radio is referred to as the SINCGARS SIP. The primary improvements relate to the data transmission capabilities of the system. A forward error correction appliqué was implemented in the receiver and/or transmitter, and a new packet data mode was created to better support packet networks. In addition, an improved channel access protocol was added, which optimizes data throughput performance while minimizing impact on voice communications on the same SINCGARS channel.

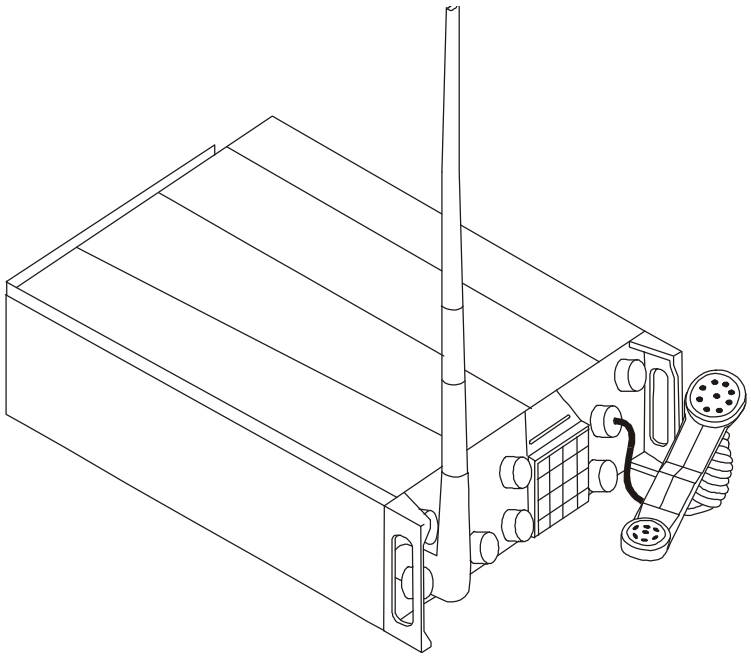

Figure 2-4. AN/PRC-119 SINCGARS Radio.

THE SINCGARS SIP radio is also available in a downsized version—the result of an advanced systems improvement program (ASIP). This radio is referred to as the SINCGARS ASIP. This radio will retain all the functionality of the full-size SIP radio but is half the size. It weighs 7.6 pounds (including the battery). The radio is interchangeable with previous SINCGARS versions, including the capability to be mounted in older vehicular adapter assemblies. A new feature of the SINCGARS ASIP provides a retransmission capability while operating in the packet data mode and will also employ a new, fast-channel access protocol for improved operations in shared voice or data nets.

The AN/ARC-210 multipurpose radio supports single-channel air-to-air, air-to-ground, and ground-to-air communications in tactical Navy and Marine Corps fixed- and rotary wing aircraft. It can transmit and receive VHF-FM, VHF-AM, and UHF signals. It is compatible with SINCGARS, HAVE QUICK, and HAVE QUICK II frequency hopping UHF radios, and it can accept 25 preset, single-channel frequencies. The AN/ARC-210 requires a TSEC/KY-58 encryption device to encrypt transmissions and decrypt received signals.

Hand-Held Very High Frequency Radios

Radio operators may have the opportunity to use various commercial off-the-shelf (COTS) VHF radios in the Fleet Marine Force (FMF). All of these radios have been open-purchased by the user units and are not part of the official Marine Corps table of equipment. Therefore, they have not been assigned a table of authorization material control number (TAMCN).

These hand-held radios are typically small, lightweight, battery-powered equipment which provides clear (and in some cases secure) voice communications on up to 100 different channels. Some models come with headsets and microphones. Hand-held radios are mostly used at the infantry-squad level or in maritime prepositioning force (MPF) offloads.

Very High Frequency Radio Employment Considerations

Operator maintenance of the radio equipment, antennas, cable assemblies, and equipment grounding as well as proper planning and selection are essential to reliable communications. Frequency separation, radio antenna separation, remote rekeying when using COMSEC, and power output are significant employment factors. SINCGARS may be limited to the single-channel mode when operating with some Navy ships. When SINCGARS is employed in the frequency hopping mode, the following operating factors need to be taken into account: hopset (i.e., frequency segment allocation), net sych time and mission date, antenna placement (cosite interference is more of a concern than in the single-channel operating mode), and power setting. SINCGARS radios configured for different hopsets that dial into the same numbered net will not be able to communicate. MCRP 6-22A provides detailed information on the employment of SINCGARS.

VHF SCR is the primary communications system for combat and combat support units while on the move. The predominant mode of operation is secure voice. However, use of VHF radio for data communications will increase with the fielding of tactical information systems at the battalion level and below. Small, hand-held VHF radios are used at the small-unit level in the MAGTF. These radios are often commercial items

that lack compatibility with SINCGARS and do not have integrated COMSEC. Their use should be governed accordingly.

Very High Frequency Radio Environmental Limitations

The primary limiting factors when using VHF radios are range and frequency availability. VHF radios can provide reliable communications for ranges of up to 10 miles, depending on the equipment operating constraints and the operating environment. Unit location must be considered when employing radios that operate in the VHF spectrum. Most circuits are limited to radio line of sight, known as four-thirds earth curvature. VHF radio signals essentially follow the curvature of the earth to a distance that is approximately one-third greater than the distance to the horizon. Foliage interferes with VHF signals and may reduce normal operating ranges to significantly less than 10 miles.

Very High Frequency Propagation

Radios in the SINCGARS family are the principal VHF transceivers used by the Marine Corps. The mode of communications used in this range is frequently referred to as frequency modulation. VHF will extend slightly beyond line of sight due to diffraction or bending of the signal by the atmosphere (see fig. 2-5). At frequencies in the 30-MHz range, VHF will often act like HF ground wave. The range of reliable communications is generally no more than 15 to 20 kilometers (9.3 to 12.4 mi) under normal field conditions for manpack equipment. Vehicle-mounted equipment may communicate farther because of higher transmitter power and better antennas.

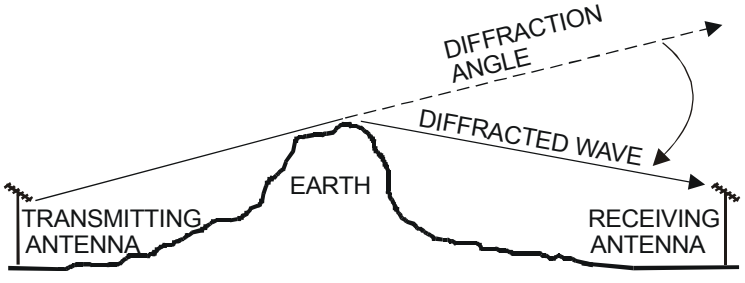

Figure 2-5. VHF Diffraction.

VHF LOS can also be plagued by multipath interference when the direct ray and a reflected ray traveling over a slightly longer path combine at the receiver antenna so that they periodically cancel or reinforce each other (see fig. 2-6). The signal fades in and out over a period of time as a result. Fading is not as great a problem with immobile equipment because corrective action can be taken, but fading can cause significant problems when one or more of the units are mobile.

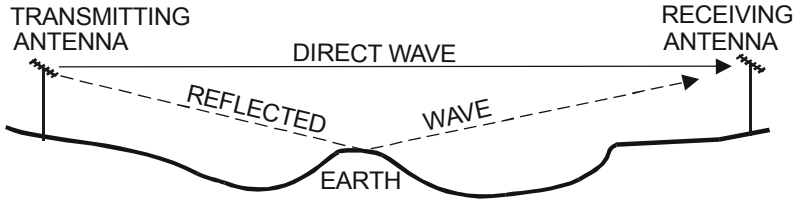

Figure 2-6. VHF LOS.

ULTRAHIGH FREQUENCY RADIO

Military UHF radio equipment operates in the 116 to 150 MHz upper-VHF frequency range and the 225 to 400 MHz military UHF radio spectrum. MAGTF UHF radio sets such as the AN/PRC-113 (see figure 2-7 on page 2-12) are capable of data communications at 16 kbps under optimal conditions. MAGTF ground and airborne UHF radios incorporate the HAVE QUICK Electronic Counter-Counter Measures capability and operate in single-channel and frequency hopping modes. The HAVE QUICK UHF radio is capable of remote operation by using the AN/GRA-39B or HYX-57.

Ultrahigh Frequency Radio Employment Considerations

UHF radios are used for forward air control (FAC) ground-to-air communication. Line of sight between radios is critical for reliable communications. Significant range differences are encountered between UHF radios employed for ground-to-air and ground-to-ground communications. Greater range is achieved when employed from ground-to-air because of the increased line of sight. When UHF radios are employed in

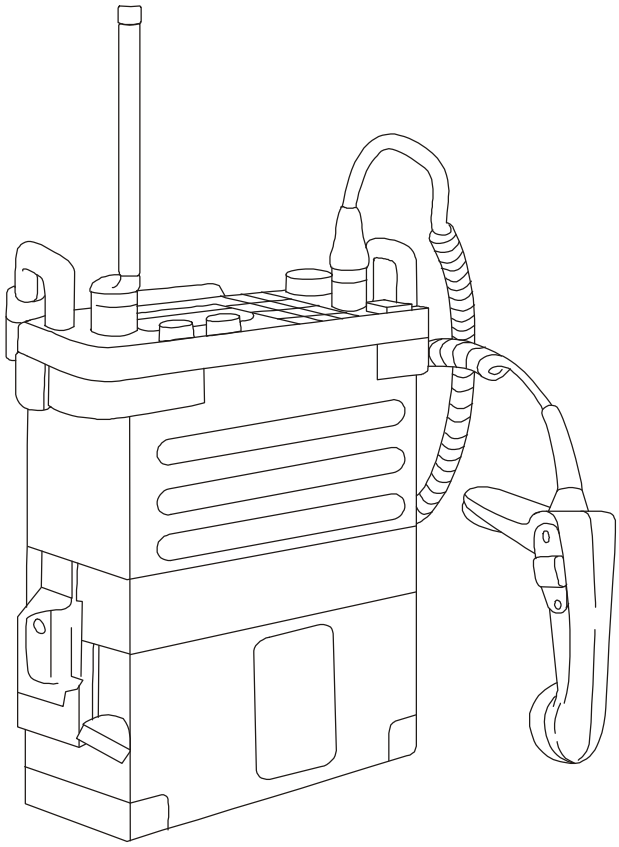

Figure 2-7. AN/PRC-113. UHF Radio.

the frequency hopping mode, the following operating factors must be understood for proper operation: hopset, time of day, antenna placement, and power setting.

Ultrahigh Frequency Radio Environmental Limitations

The primary limiting factor when using UHF radios is range (i.e., critical line of sight). Critical line of sight can be described as "what you see is what you get." As long as the radio's antenna has optical line of sight to another radio's antenna, the two will be able to transmit and receive. For this reason, UHF radios are used primarily in air-to-ground communications.

Ultrahigh Frequency-Tactical Satellite

The AN/PSC-5 is a portable, battery-operated, half-duplex UHF transceiver. It is employed for long-range communications. It weighs approximately 14 pounds including antenna and batteries. The AN/PSC-5 provides two-way voice and data communications by satellite. It operates on the UHF frequency band of 225- to 400-MHz range. It provides 2,400 to 16,000-bits per second (bps) data rate, depending on mode setting. Only one operator is required to operate it. The United States Marine Corps UHF tactical SATCOM system supports and augments the high precedence command and control and common-user, single-channel requirements of a Marine air-ground task force and its major subordinate headquarters.

The space segments used by the AN/PSC-5 are the Fleet Satellite Communications, leased satellite communications, and UHF follow-on satellites. All the satellites are located in geosynchronous orbits and permit interconnections among mobile, ground terminals. The one-way distance to servicing satellites is approximately 25,000 miles, resulting in a round-trip propagation delay of approximately one-quarter of a second. The shape of the satellite footprints is roughly circular but elongated from north to south. This is caused by the angle at which the signal hits the Earth's surface and by the curvature of the Earth's surface.

Multiple-access schemes can operate either with fixed-channel assignments to the various users or with channels being assigned in varying fashion according to demand. The latter is called demand assigned multiple access (DAMA). With demand assignment, the user makes a channel request, and a channel is allocated after a brief time lag. The DAMA scheme of operation is employed on UHF-tactical satellite (TACSAT) to share available channels more efficiently. The radio systems are compatible with the KY-57 (wideband mode only), the KY-99 and ANDVT (narrowband mode only), and the KG-84C (wideband or narrowband) COMSEC equipment. This radio equipment is also capable of remote operations by using the AN/GRA-39B (narrowband mode) or HYX-57 (wide-band mode).

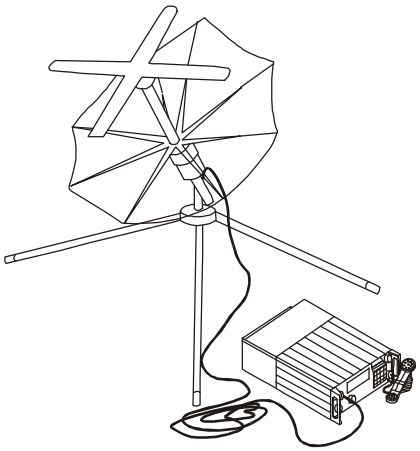

Figure 2-8. AN/PSC-5 UHF TACSAT Radio.

TACSAT Radio Employment Considerations. Because of TACSAT's limited availability, the MAGTF employs TACSAT primarily to support critical, long-range communications requirements (e.g., communications support for deep reconnaissance operations or connectivity to the tactical echelon of a MEU[SOC] when deployed ashore). The AN/PSC-5 is the primary DAMA-capable, TACSAT radio available to the MAGTF (see fig. 2-8). TACSAT limitations include the competition for available frequency resources and channel time on the satellite. If only narrow band channels are available, channel-data rates are limited to 2,400 bps. Channel congestion, noise, and network saturation will affect the information flow on satellite channels and will require a significant reduction in the data transmission rates to sustain data communications. Transmit power selection can be critical. Increasing the transmit power can decrease net effectiveness. Larger directional antennas provide increased signal gain, which increases the transmitted signal power. Antennas for these systems are lightweight and fragile and, therefore, require constant maintenance and inspection for proper operation. Satellites are shared resources. Exact frequency, bandwidth, and power of every carrier transmitted through the satellite is strictly controlled by a higher authority.

TACSAT Radio Environmental Limitations. The primary environmental limitations on TACSAT radios are signal propagation delay, location on the Earth, terrain masking, and weather effects. Timing between DTE can be a critical factor in SATCOM because the satellite, acting as a relay between radios, is about 25,000 miles away. There is

approximately a one-fourth second propagation delay between sending and receiving stations. This delay can interfere with systems that automatically retransmit if an acknowledgment is not received after a very short time-out period. As unit location changes, the "look angle" (i.e., angle above the horizon) to the satellite can affect net reliability. The orbit of a satellite allows it to cover a certain footprint on the earth. Satellites in equatorial orbit can cover large portions of the Earth, both north and south of the equator, but as the user moves closer to the Earth's poles, the TACSAT terminal may exceed the satellite footprint. This will cause intermittent or lost communications. Terrain can also have this effect by interfering with the satellite and TACSAT terminal line of sight. Thunderstorms, heavy snowstorms, and hail also affect satellite transmissions by damaging antennas and changing the electromagnetic environment.

Ultrahigh Frequency Propagation

UHF frequency propagation is used for ground-to-air, air-to-air, satellite, and tactical multi-channel communications. Communications are limited to LOS but may extend for more than 500 kilometers as long as the aircraft is high enough to be within LOS (see fig. 2-9). It is even possible for UHF communications ranges to a satellite to be more than 35,000 kilometers.

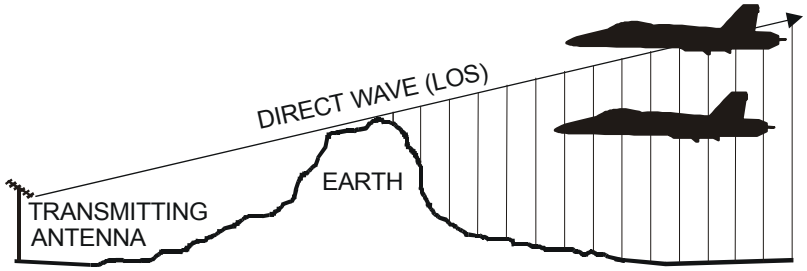

Figure 2-9. UHF LOS.

DATA COMMUNICATIONS

SCR can also transmit and receive data by using terminal devices such as the digital message system (DMS)—previously called and more commonly known as the digital communications terminal (DCT)—and the tactical communications interface module (TCIM). The DCT, data

automated communications terminal (DACT), and the TCIM are critical in enabling data communications at the tactical level over SCRs.

Digital Message System-AN/PSC-2

The DMS-AN/PSC-2 is a hand-held communications device that can be operated with either a standard military radio or telephone field wire equipment. The DMS is used to compose, edit, display, transmit, and receive information. By menu selection, formatted text, free text, and digitized map messages are transmitted over tactical communications equipment. DMS is being used directly for air support, fire support coordination, reconnaissance, medical evacuation, and other functions. DMS uses a burst transmission capability which reduces the vulnerability to enemy radio direction finding and jamming.

Data Automated Communications Terminal

The DACT is a small, tactical computer and communications terminal which gives users the capability to receive, process, and transmit various messages, to include text and symbology, used by tactical data systems. The DACT will effectively replace the DCT when it achieves full operational capability in FY 03, and it will provide much greater functionality below battalion levels. This will include an embedded global positioning system (GPS) receiver, the ability to share a common picture of the battlespace, automated data exchange, and MAGTF command, control, communications, computers, and intelligence (C4I) network connectivity. The DACT will be transportable by foot-mobile Marines and mounted in tactical or armored vehicles.

Tactical Communications Interface Module

The TCIM provides the communications link between the tactical computers of the communications and information systems within the MAGTF and the local and wide area networks, switched backbone (SBB), and radio nets. There are two versions of the TCIM card: an internal personal computer asynchronous transfer card to mount directly in the computer, and an external version with the card mounted in a portable chassis. TCIM software was developed for open-systems architectures. Small computer systems interfaces (SCSI) provide interoperability between the TCIM and other Marine Corps computers.

Chapter 3

Equipment Siting and Grounding Techniques

Two factors play an important role in equipment siting: optimum communications and camouflage. It is often difficult to find communications sites which are hidden from enemy view, fire, and direction finding and afford good communications connectivity. The ideal location for a radio antenna is as far away from cover as possible, such as a bare mountain top or in the middle of a large field. However, this goes against the commander's tactical requirement for troops and equipment to be camouflaged and concealed as much as possible. Therefore, planning the location of equipment must be detailed to achieve the best results. See Appendix A for a review on topographical maps and grid coordinates.

HIGH FREQUENCY

In the presence of hills (without large trees), the following guidelines for ground wave links should be used:

- Locate HF antennas just below the top of the hill in the direction of desired communications. Often the signal will be greater below than on the top. This will also minimize interference and/or jamming from the opposite direction.
- Move the antenna back from the hill if a hill is between the operator and the distant station with which the operator wishes to communicate. The signal strength can vary widely in the region immediately behind a hill. If it is necessary to set up behind a hill, then it may also be necessary to set up a variety of antennas located at different distances from the hilltop to see which one offers the best performance.

Long-distance, HF sky wave signals of more than several hundred kilometers are often best transmitted and received at angles just above the horizon level. Obstacles on the horizon will cause the signal to travel a

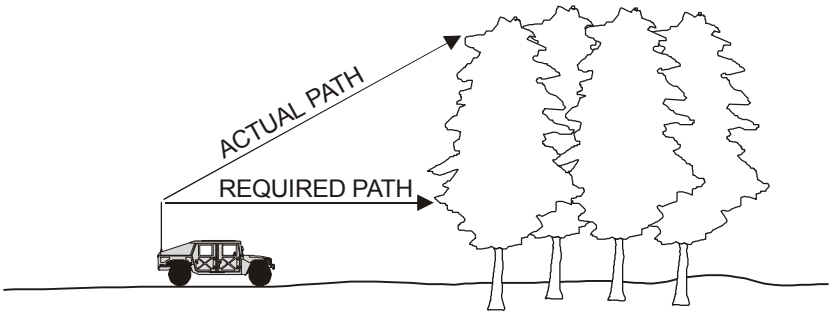

Figure 3-1. Low HF Horizon Angles.

higher path angle and may reduce the circuit reliability as a result (see fig. 3-1). Wire fences between the operator and the horizon will also lessen the chances of getting through (see fig. 3-2).

An HF ground wave signal will follow the terrain much better than higher frequency signals. It will be weakened by trees (more so when

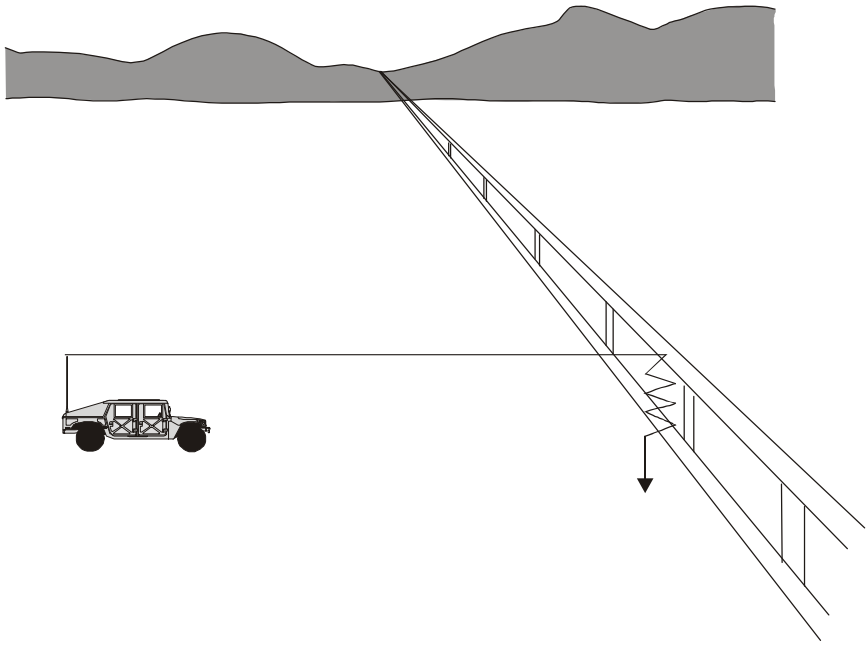

Figure 3-2. Effect of Wire Fences and Power Lines.

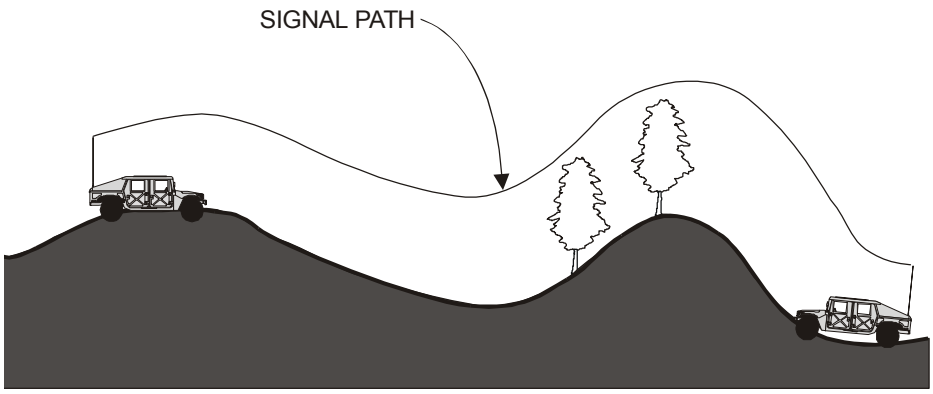

Figure 3-3. HF Ground Wave Path.

they have leaves) and rugged terrain, but the signal may still get through (see fig. 3-3).

VERY HIGH FREQUENCY AND ULTRAHIGH FREQUENCY

Obstacles such as trees, buildings, and hills between a transmitter and receiver will weaken the signal or stop it. Aircraft flying along the path will also interfere with reception (see fig. 3-4). A clear signal path

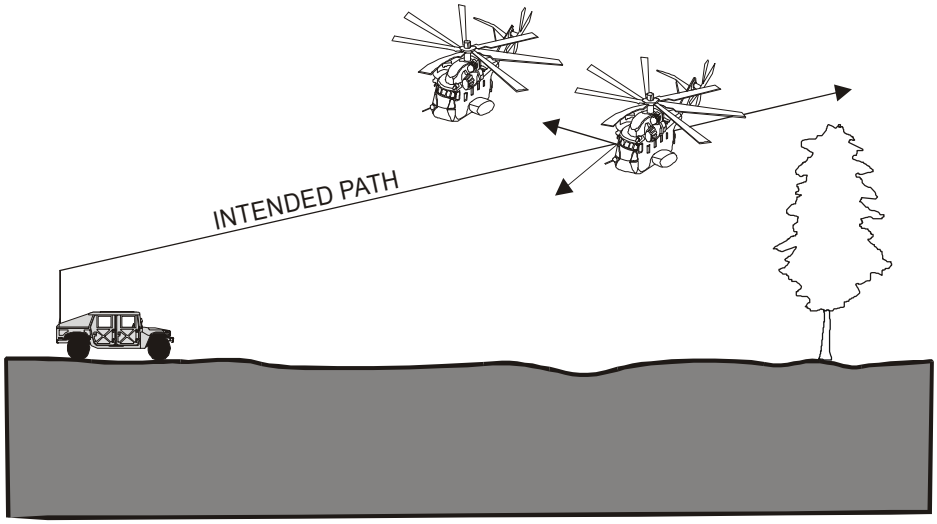

Figure 3-4. Aircraft Along Signal Path.

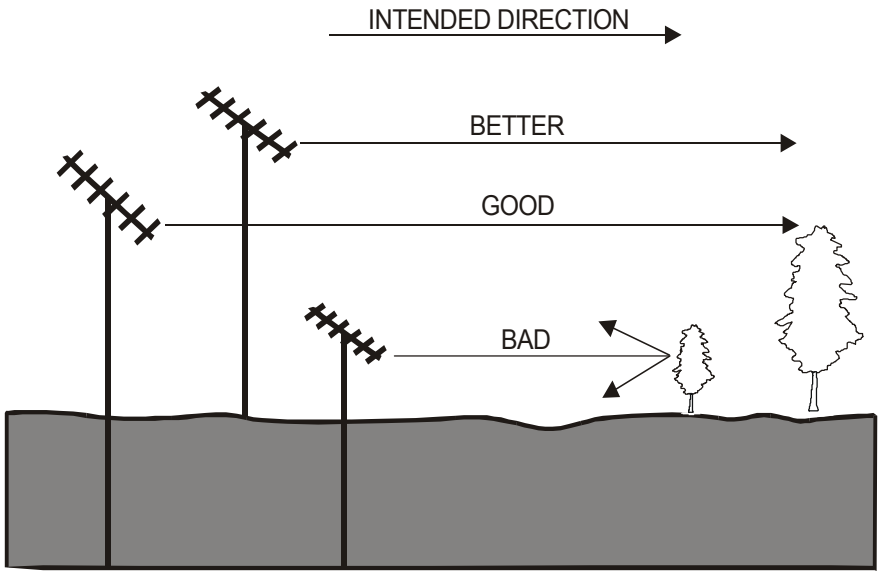

Figure 3-5. Antenna Obstacles.

between the transmitter and the intended receiver, especially for LOS communications, is preferred. The antenna must be positioned as high as possible to overcome obstacles, especially if communication is in the direction of trees or buildings (see fig. 3-5). Keep equipment as far back as possible from obstacles in the direction of the signal path to prevent interference or damage to equipment.

In some situations, solid obstacles may actually improve a link by providing a sharper surface to diffract over or reflect from (see fig. 3-6).

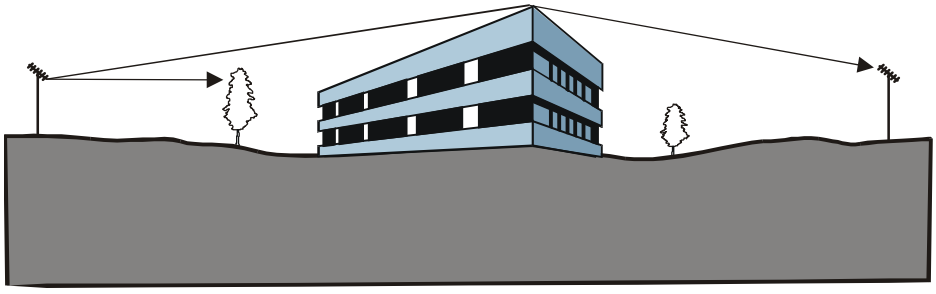

Figure 3-6. Diffraction Over Building.

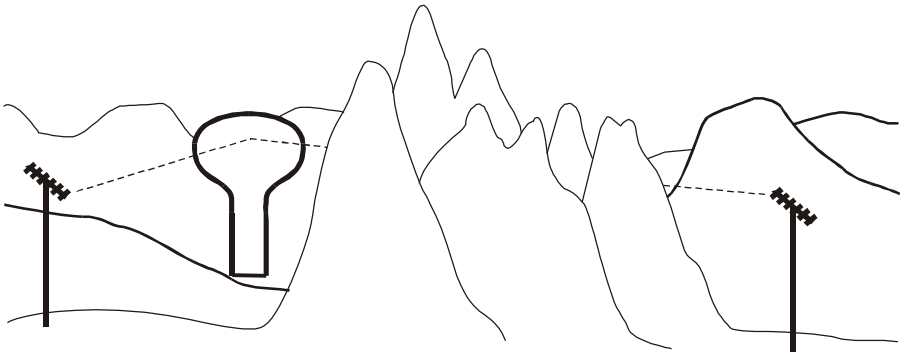

Figure 3-7. Reflection off Spherical Water Tower.

Under certain conditions, spherical water towers and walls of buildings (facing the proper direction) may enable communication around interfering terrain or vegetative obstacles (see fig. 3-7).

Transmitting over water allows VHF to go farther, but fading may occur. If communicating over water is unavoidable, and fading occurs, the signal may be improved by raising or lowering the antenna. The antenna may also be positioned so a hill or rise is between it and the water but not high enough to block the LOS to the other antenna (see fig. 3-8).

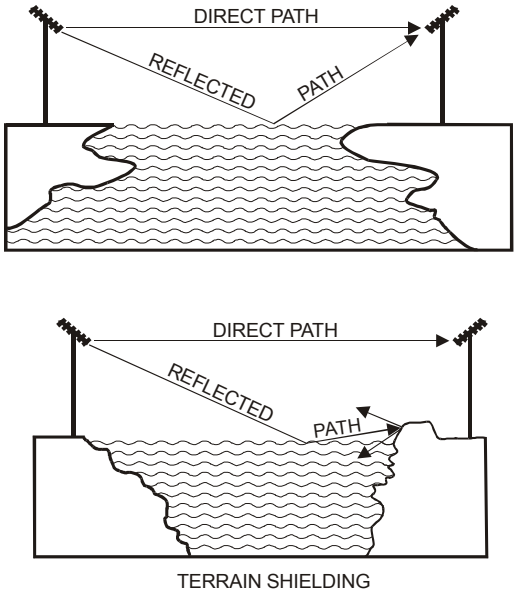

Figure 3-8. Multipath Fading and Terrain Shielding.

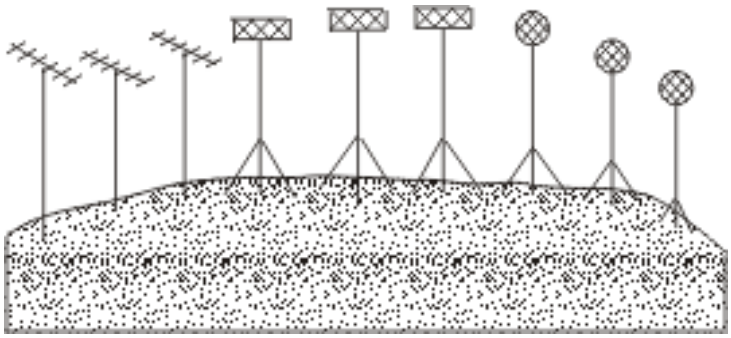

Figure 3-9. Ridge Line Antenna Farm.

Nothing is more compromising to a unit's location than an antenna farm stretched along a ridge line (see fig. 3-9). The enemy will realize that a major command post is nearby. The advantage of placing an antenna on a ridge line is the ability to talk in many directions without land being in the way. If communication is needed in only one direction—away from the enemy—put some terrain shielding between the antenna farm and the enemy (see figures 3-10 and 3-11). This way, the enemy won't be able to intercept communications or jam circuits as easily. However, it's not always necessary to talk from hilltop to hilltop. Talking from hillside to hillside or along the valley floor may be a better option in some instances. The enemy will certainly have a harder time locating a unit this way.

Figure 3-10. Low Antenna Profile.

Figure 3-11. Terrain Shielding.

The body can act as an antenna and affect the quality of the radio signal, particularly backpack and hand-held VHF sets with short antennas. The effect of the body on signal strength depends on frequency, antenna length, and the position of the antenna or set relative to the operator's body (see fig. 3-12 on page 3-8).

Backpack Sets (AN/PRC-119)

Maximum radiation (i.e., best performance) is to the front when the set is on the operator's back with a 3-foot whip antenna. The operator should then try facing in the direction of distant communications. This effect is most noticeable at frequencies greater than 50 MHz.

When the set is on the ground, and the operator is very close to the set, maximum radiation will probably occur through the operator's body. If the operator is a couple of feet away, the operator may act as a reflector and either improve or interfere with the signal.

Hand-Held Sets (AN/PRC-68)

The antenna of the hand-held AN/PRC-68 is much smaller than the AN/PRC-119's, and the operator's body affects directional characteristics to

Figure 3-12. Direction of Best Communications.

a greater extent, particularly when the antenna is lowered. This radio will normally be in the front jacket pocket, and best performance is then over the back. The higher frequencies are strongly affected when the antenna is lowered. Holding the radio in hand a few inches away from the body will modify the radiation pattern and can substantially lower performance to the sides at the higher frequencies. The directional characteristics of the antenna-body combination can be used to some advantage in reducing interference arriving from directions other than that of the signal. Trial and error is necessary to make this judgment.

VHF Siting

Position the antenna to reflect the directive pattern away from the wall or fence in the intended direction of communication when using VHF antennas near a metal-walled building or high, metal fence. For frequencies between 30 and 50 MHz, the antenna should be placed approximately 2 meters (6.5 feet) away; between 50 and 88 MHz, no more than 1 meter (3.2 feet) away. Communications may be reduced if antennas are placed more than 2 meters from the radio. The distance may be varied a

foot or so in each direction, while receiving, to find the position where the signal is the strongest when setting up the equipment. If frequencies are changed later, the optimum position will have to be redetermined at that time by the same method.

UHF Siting

At UHF and (to a much lesser degree) VHF frequencies, if an operator cannot see a person, then they probably cannot communicate—especially in heavy vegetation. Often, the signal has to travel up to the tops of the trees and move along the treetops and down to the receiver (see fig. 3-13). This will weaken it considerably. In vegetation, the antenna should be positioned away from trees that are in the direction of the signal and erected as high as possible. Changing the location of the antenna is also an option. Both horizontal and vertical orientations may be used with the AS-4225 Parabolic Grid Antenna with UHF multi-channel (MUX) radio equipment. Horizontal polarization is usually better for passing through the trees, but if the signal is skimming over the tops of the trees (probably unnoticeable) or over water, then the polarization should be vertical (see fig. 3-14 on page 3-10).

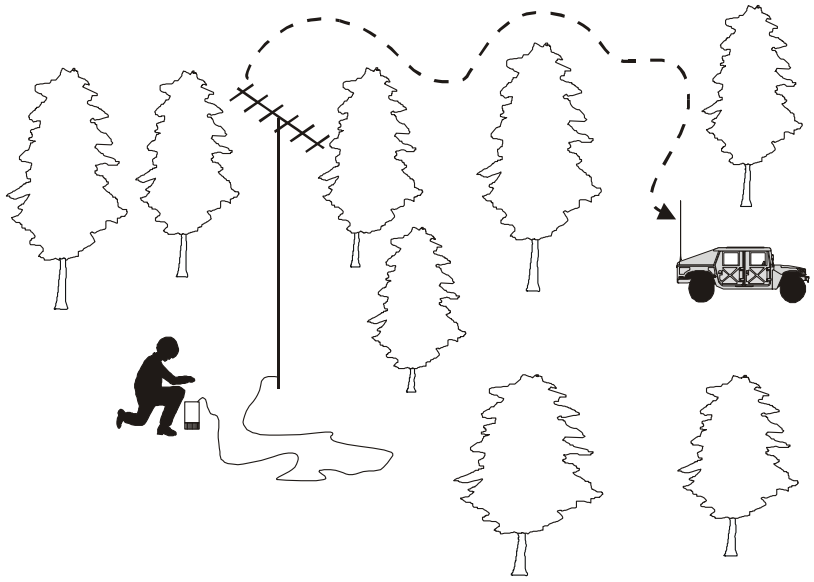

Figure 3-13. VHF Vegetative Propagation.

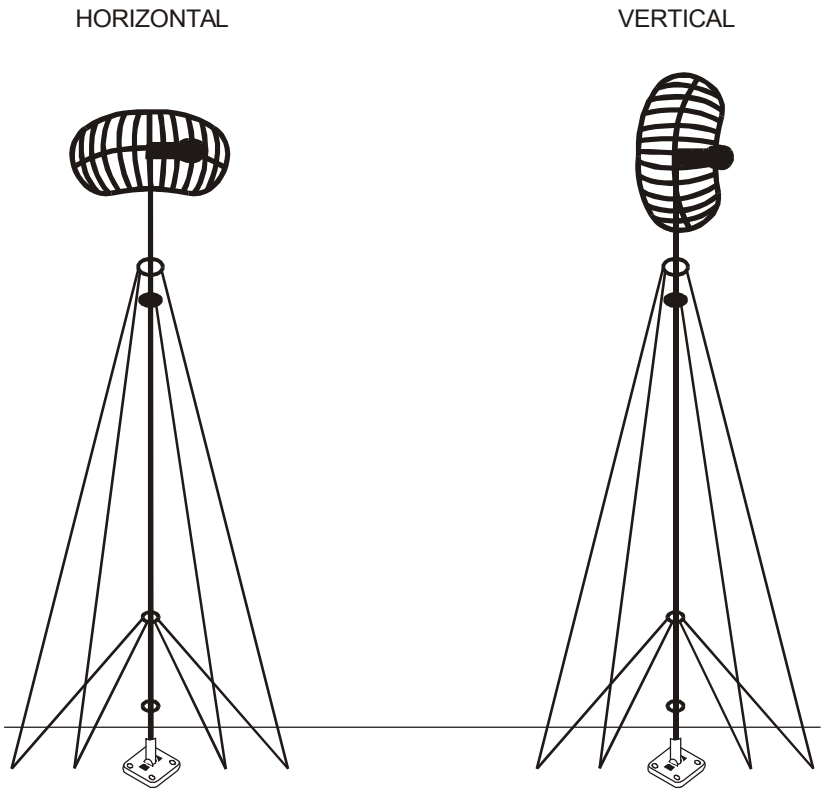

Figure 3-14. AS-4225 with AB-1356 Antenna Polarization.

GROUNDING TECHNIQUES

Poor grounding is probably the most important cause of a weak HF signal. Communication distances can easily be cut in half by improper grounding of the antenna. More importantly, the hazards involved with improper grounding coupled with high transmitter powers are bad burns, electrical shocks, or even death (see fig. 3-15).

Grounding prevents electrical shock to operator and improves signal strength, particularly in HF.

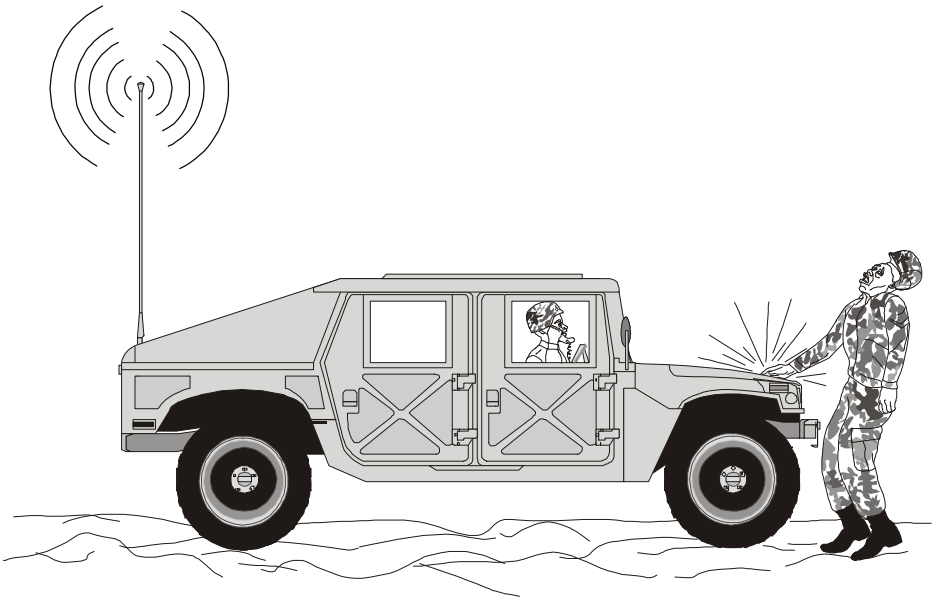

Figure 3-15. Shock Hazards of Ungrounded Equipment.

Ground Stake

The ground stake provided with the antenna should be driven deeply into the soil, making certain all connections are tight and clean. Soil moisture and salinity around the ground stake are very important for good grounding. If a dry or a damp location is available, choose the damp spot. If everything is bone dry, a couple of gallons of water poured around the stake may help. Adding a pound or two of salt from the mess tent to the soil around the stake before soaking it may help even more.

If a regulation ground stake is not available, there are many field-expedient means for grounding. The primary concern is to provide an electrical path from the equipment case, using braided copper or heavy gauge wire, to a buried metallic object that is in good contact with the ground. All cable connections and grounds should be free of grease, paint, or rust. Cables should be as short as possible.

Some useful grounds are—

- Metal fence posts.
- Steel reinforcing rods.

- Metal pipes.
- Metal plumbing (must not be connected to flammable liquid or gas).
- Metal building frames.

Ground Radials

A ground radial system (i.e., counterpoise) is necessary to reduce the amount of power lost in the earth (see fig. 3-16). This is particularly important for HF whips, inverted As, and other vertical antennas. The radial system design is usually a compromise between performance, portability, and time to install the system. Ground radials help to establish a known reference point of electrical ground. Without them, electrical ground may be some distance beneath the Earth's surface. Known electrical ground is important not only for formation of the wavefront off the antenna, but it also affects launch angles from antennas.

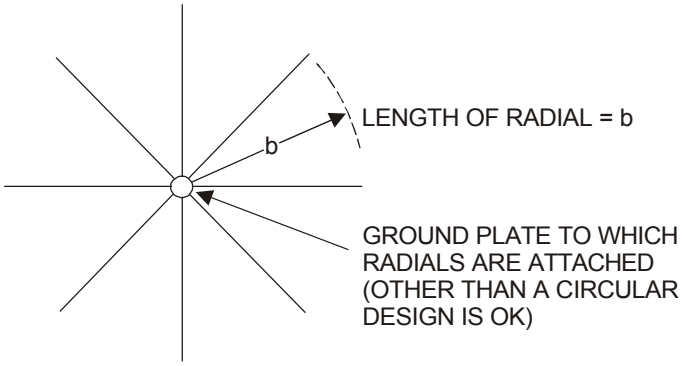

Figure 3-16. Radials.

Radials are attached metal-to-metal to a central point (a metal plate is often convenient). The radio frequency (RF) ground is attached to the central plate (Figure 3-17).

Wire diameter is not critical; select a diameter small enough to be lightweight and transportable, but large enough to prevent breakage. The largest number of radials to transport should be consistent with weight and bulkiness limitations. It is not necessary to make them greater than one-quarter wavelength at the lowest operating frequency.

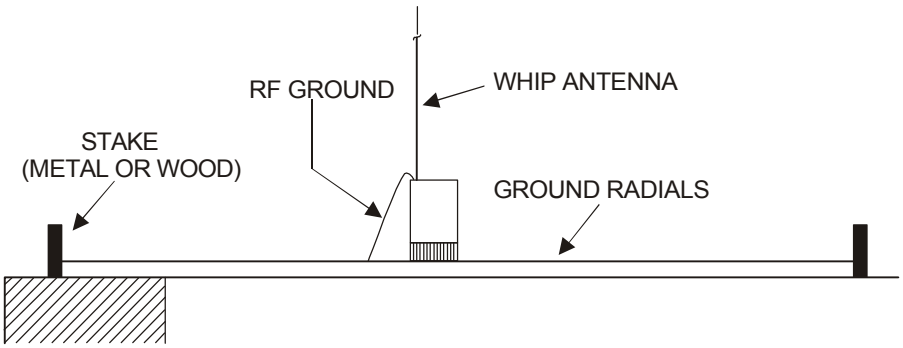

Figure 3-17. Equipment Configuration.

One-quarter wavelength = 74.9 meters
frequency (MHz)

Suggested dimensions:

5 meters (15-foot whip): N (number of radials) = at least 30 (one every 12°)
b (length of radial) = 7 meters (23 feet)

10 meters (32-foot whip): N = at least 30
b = 14 meters (46 feet)

If the site is semipermanent (i.e., several days or more), the number of radials should be increased to 100, and their length doubled.

Make radial systems for each antenna prior to an operation. Short stakes at the ends may be used to hold them in position when deploying. Ground all radios, where possible.

(reverse blank)

Chapter 4

Antennas

This chapter will discuss high frequency and very high frequency antennas. Antenna designs that work for HF sometimes work for VHF and vice versa. The main difference is size; HF antennas are considerably larger than VHF antennas. Ultrahigh frequency antennas are generally limited to whips. When determining the best antenna to employ with a circuit, consult MCRP 6-22D for more detailed information on antenna propagation characteristics, as well as construction considerations and procedures.

HIGH FREQUENCY ANTENNAS

Vertical Whip

A vertical whip antenna (i.e., whip) will most likely be used with an HF radio. The whip is particularly good for ground wave communications in many directions at one time, at distances of 20 to 30 kilometers. Unfortunately, while it is radiating in all directions at the same time, it is also picking up interference from all directions. It is useless if using sky wave over a distance of 100 kilometers, because of the high radiation angles required. (NOTE: Launch angles off vertically polarized whip antennas are maximum below 45°.) A vertical whip's performance by sky wave, however, improves with increased path distances.

A vehicle-mounted whip, tied down fairly close to the vehicle, may be efficiently employed in short- and intermediate-distance HF sky wave communications. A whip, tied back only a little, may be useful in long-distance HF sky wave applications.

Sloping Wire

If an HF circuit is only a single point-to-point ground link or a ground wave net with all other terminals being located in the same direction, a

sloping wire may be used, if available. The radiating length of the AT-984 "Fishreel" antenna (a 45-foot long, wire antenna which can be used with the AN/PRC-104) can be varied by either connecting or disconnecting the alligator clips. (Antenna length is measured from the radio equipment.) See Table 4-1 to determine how long an antenna should be cut to form an assigned frequency.

Table 4-1. Sloping Wire Antenna Lengths.

Frequency	Length	
MHz	(Feet)	(Meters)
5	45	13.7
9	25	7.6
12	15	4.6

The far end of the antenna should be connected to a rope with a weight, such as a stone or brick or other nonconducting material tied to the end. The weighted end should be thrown over a tree so that the antenna forms a 30° to 45° angle to the ground. Angles higher than 45° should be used for ground wave, and lower angles for sky wave. The high end should be opposite the direction of the intended receiver (see fig. 4-1).

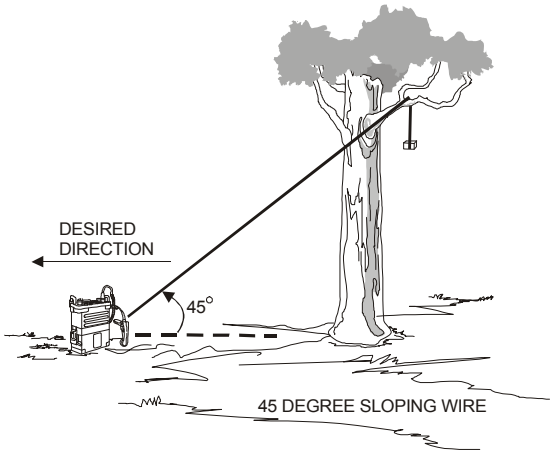

Figure 4-1. 45° Sloping Wire Antenna.

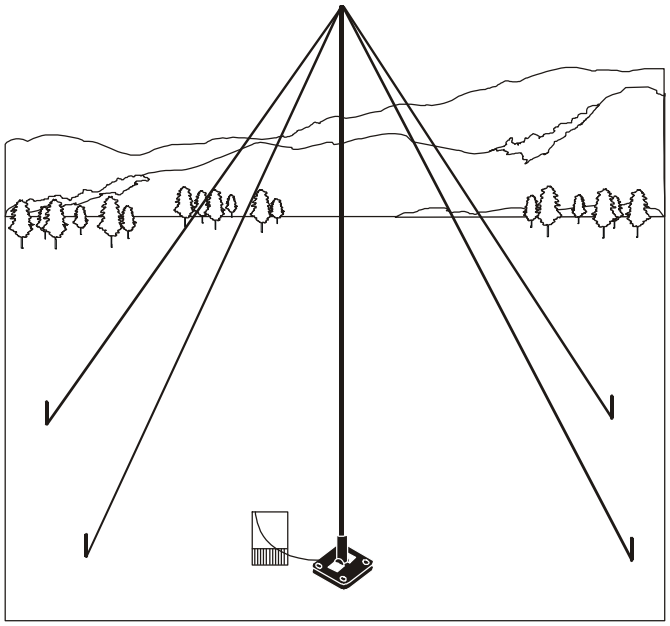

Figure 4-2. AS-2259.

AS-2259 Near-Vertical Incidence

Another HF antenna is the AS-2259 (see fig. 4-2). Although not suitable for frequencies under 3.5 MHz, this antenna can be used for both ground wave and sky wave. The AS-2259 will often enable an operator to communicate in a skip zone when a whip antenna will not. In addition, it can sometimes be used effectively to communicate by sky wave over a hill or mountain obstacle that would otherwise block a ground wave signal. More detailed information regarding HF NVIS antennas can be found in MCRP 6-22D.

Horizontal Half -Wave Dipole (Doublet)

The horizontal half-wave dipole (also known as the doublet) is frequently used for short to medium HF sky wave paths (up to about 1,500 kilometers). It is usually installed at one-quarter wavelength of the operating frequency above ground (see fig. 4-3 on page 4-4). The major drawback of this antenna is the unusually long length required (up to 71

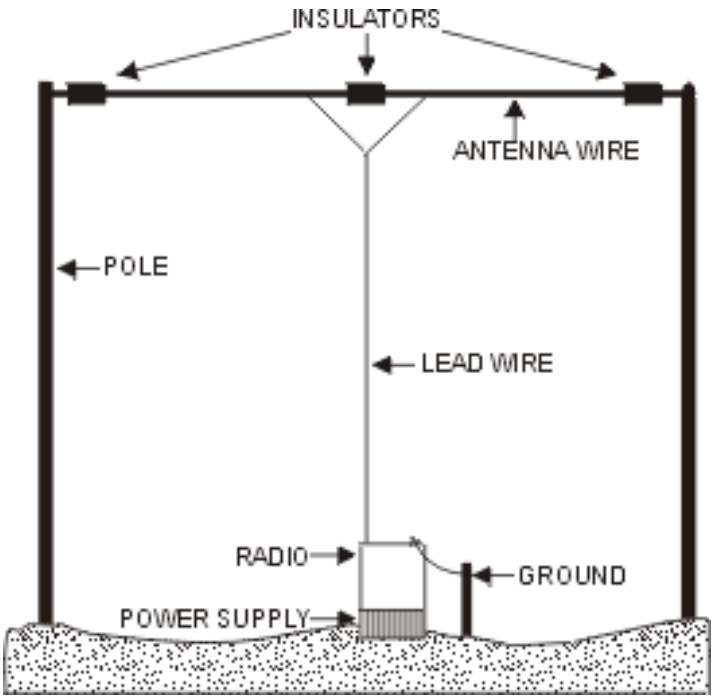

Figure 4-3. Doublet Antenna.

meters [233 feet] at 2 MHz). NOTE: A 2 percent or greater error in length means less efficiency and a loss of radiated power.

Inverted L

Inverted L antennas are useful for NVIS propagation (see fig. 4-4). Because of their construction, they also yield better ground wave radiation than whip antennas. Inverted L antennas can be effectively employed with a wider range of frequencies than can horizontal half-wave dipole antennas.

Antenna Enhancements

Several pieces of equipment which improve the capabilities of standard Marine Corps communications equipment are available from commercial sources. These items are not stocked in the Marine Corps supply system. They must be purchased directly from commercial sources.

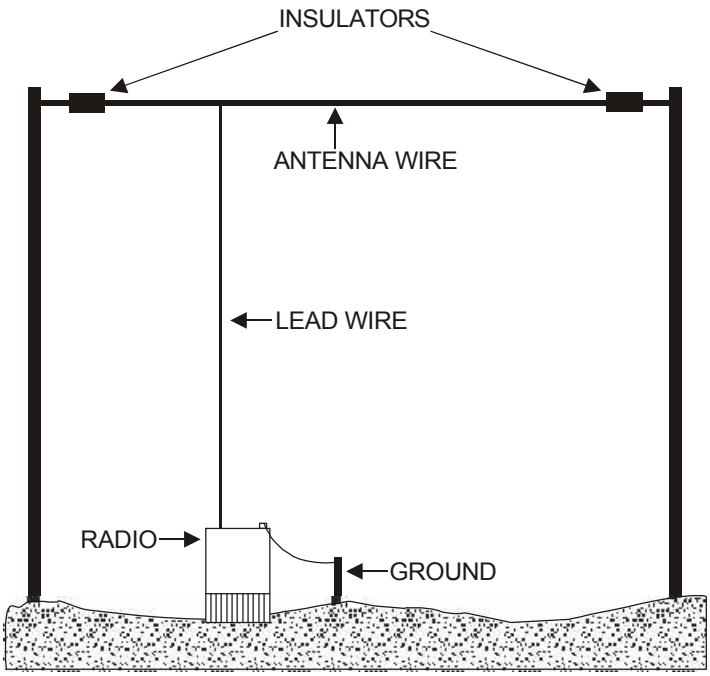

Figure 4-4. Inverted L.

They include—

- Tilt whip adapter (TWA)—used with the vertical whip antennas issued with AN/MRC-138 radio. These antennas can be tilted to obtain the correct angles for NVIS communications. The TWA made for the AN/MRC-138 is one piece and has a simple design. When fitted with a TWA and only the top four sections of the AT-1011 antenna, the AN/MRC-138 can be operated on the move.
- Whip loading coil (WLC)—used with the WTA for the AN/MRC-138. This device makes the antenna more efficient at lower frequencies.
- Whip to wire adapter (WWA)—screws into the top one-inch-diameter section of the AT-1011, thus allowing the operator to use the one-inch-diameter section of the AT-1011 as the mast for field-expedient antennas.

- Whip-base adapter (WBA)—allows the whip antennas for Army HF radios to be used with Marine Corps HF radios. The whip antennas for Army HF radios are of a different size than the whip antennas for Marine Corps HF radios.

For further information about commercial equipment which can improve the capabilities of Marine Corps radios, contact the G-6/S-6 sections of higher headquarters.

VERY HIGH FREQUENCY ANTENNAS

OE-254

This antenna is used with VHF-FM radios to increase the operating range beyond that of a normal whip. The two elements hanging down from the antenna form a ground-plane similar to the ground radials discussed in chapter 3. The effect is to act as an artificial ground and greatly increase the signal range. The antenna radiates in all directions at the same time. The OE-254's elements allow it to tune to frequencies between 30 and 88 MHz without manually adjusting either the ground-plane or radiating elements' length. Figure 4-5 illustrates the OE-254 antenna.

Vertical Whip

VHF whip antennas are usually limited in range from 15 to 20 miles. A whip antenna is omnidirectional; therefore, it has the potential to produce a great deal of radio-wave interference with the radios in the area. It is important when using a whip antenna or any antenna to keep maximum distance between antennas. Use of hills and other terrain features to block off unwanted signals will improve desired signal strength. When using whip antennas with backpack or hand-held equipment, body position may increase the transmitted and received signal. This is because the human body acts as an antenna. If experiencing communication problems, the operator should try facing in different directions to improve the reception of the signal.

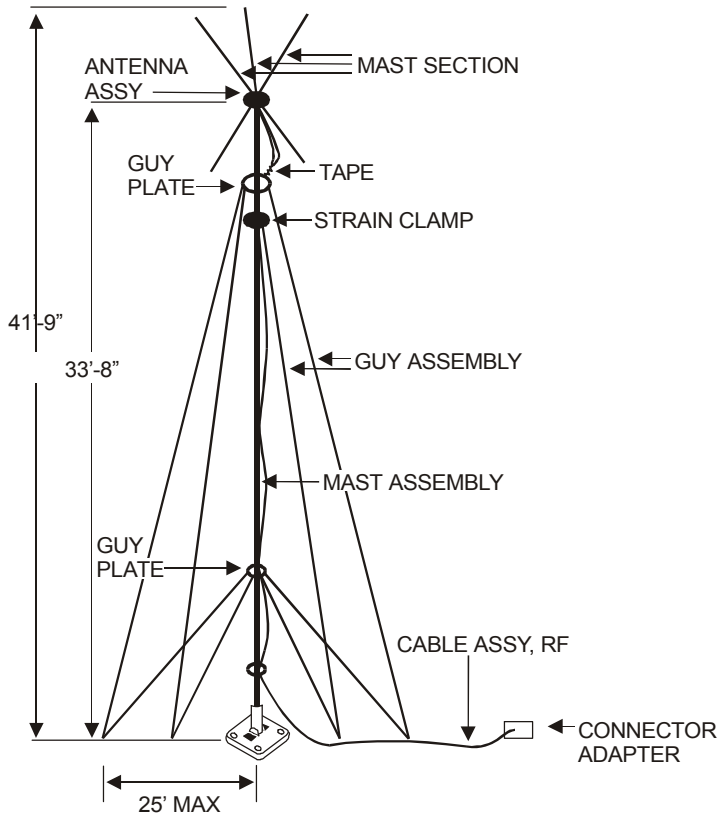

Figure 4-5. OE-254 Antenna.

ANTENNA LENGTH

The length of an antenna must be considered in two ways. It has both a physical and an electrical length, and the two are never the same. The reduced velocity of the wave on the antenna and a capacitive effect (known as end effect) make the antenna seem longer electrically than it is physically. The contributing factors are the ratio of the diameter of the antenna to its length and the capacitive effect of terminal equipment (e.g., insulators, clamps, etc.) used to support the antenna.

To calculate the physical length of an antenna, use a correction of 0.95 for frequencies between 3.0 and 50.0 MHz. The following figures are for a half-wave antenna.

Length (meters) = 150 x 0.95/Frequency in MHz
= 142.5/Frequency in MHz

Length (feet) = 492 x 0.95/Frequency in MHz
= 468/Frequency in MHz

The length of a long-wire antenna (one wavelength or longer) for harmonic operation is calculated by using the following formula:

Length (meters) = 150(N-0.05)/Frequency in MHz
Length (feet) = 492(N-0.05)/Frequency in MHz

N = number of half-wave lengths in the total length of the antenna.

For example, if the number of half-wavelengths is 3 and the frequency in MHz is 7, then:

Length (meters) = 150(N-0.05)/Frequency in MHz
= 150(3-.05)/7
= 150 x 2.95/7
= 442.50/7
= 63.2 meters

Chapter 5

Interference

Radio frequency interference is always present in a military environment. It may come from a single source or a combination of many sources including natural or manmade frequency interference, poor equipment condition, improper equipment usage, frequency interference, use of unauthorized frequencies, and frequency reuse.

NATURAL INTERFERENCE

Natural radio noise has two principal sources: thunderstorms (atmospheric noise) and stars (galactic noise). It is especially noticeable at night when the lower frequencies propagate farther than in the daytime. The only way to reduce this type of interference is to use a directional antenna to prevent receiving the interference from all directions. However, this will not eliminate the noise coming from the direction of the received signal. Use of a higher frequency will also help, although if a sky wave circuit is used, care must be exercised not to pick the highest frequency at which the signal will be refracted to Earth by the ionosphere (i.e., the critical frequency).

MANMADE INTERFERENCE

Most manmade interference comes from electrical sources such as power generators, alarm systems, power lines, auto ignition, fluorescent lighting, faulty electrical relay contacts, and electrified railroads. Manmade interference also includes enemy jammers (see chapter 7). The key to combating this form of interference is to isolate communications equipment from manmade interference. The interference from known sources such as generators can be greatly reduced if an antenna is positioned so that an obstacle (e.g., a hill) is between it and the source. This must be done so that the same obstacle will not block the intended radio path. If the interference is not coming from the same direction as the intended signal, then a directional antenna should be used.

POOR EQUIPMENT CONDITION AND IMPROPER USAGE

The condition of radio equipment and how it is being used may result in interference. There are several steps that should be taken to lessen this possibility. These include making certain that shielded cables are used where required, ensuring connectors are properly connected to cables, and making sure that antennas within a group are as far apart as possible. All antenna leads (transmission lines), power lines, and telephone lines should be as short as possible when they are on the ground and should not cross. If lines do cross, they must cross at 90° angles to each other, and they must be separated from each other by standoffs. Lines threaded through the trees near an antenna serve as pipelines for interference to and from antennas. Finally, ensure that all radio equipment is grounded.

FREQUENCY INTERFERENCE AND INTERMODULATION

Frequency interference is one of the easiest communications problems to prevent, but it must be done by the CIS officer, CIS chief, and frequency manager during the development of the CIS plan. This type of interference is caused primarily by two radio transmitters using the same frequency, but it can also happen when different frequencies are used. Most of these problems can be eliminated by good frequency planning. However, if frequency interference does occur the following steps can be taken to improve communications:

- Identify the source of the interference. If it is a VHF or HF ground wave transmission, it will probably be within the immediate area and will only occur when the offending transmitter is keyed. The other operator is probably transmitting on a different frequency and has no way of knowing that he is interfering with anyone else's ability to transmit.
- Get the interfering operator to lower their transmitter power as long as it does not degrade their circuit.
- Put as much distance as possible between the affected unit's equipment. This may involve using a hill or other object to block the signal.
- Change to a directional antenna.

- Remember that the receiver of interference may also cause someone else interference and, whenever possible, should lower his power and use a directional antenna.
- Report interference to the CIS officer or CIS chief.

USE OF UNAUTHORIZED FREQUENCIES

There is one final source of frequency interference: the use of unauthorized frequencies. This practice is illegal and has the potential to disrupt a carefully engineered frequency plan, introduce interference to other frequencies and circuits, and prevent other units from fulfilling their mission. Radio operators should never use unauthorized frequencies.

FREQUENCY REUSE

There are not enough radio frequencies available for all radio operators to have their own channel. When HF propagation conditions are favorable, Marines may discover that their radio frequency is being used by foreign or United States military personnel in other countries. VHF FM frequencies often have to be reused within the same operation by more than one unit. The exercise frequency manager will try to make certain that users of the same frequency are as far away as possible from each other, but some units (United States Marine Corps and Army, in particular) will join at some stage in the operation. When this occurs, the first common, higher headquarters should be informed to settle the problem.

(reverse blank)

Chapter 6

Radio Operations Under Unusual Conditions

OPERATIONS IN DESERT AREAS

Capabilities and Limitations

SCR is usually the primary means of communications in the desert. It can be employed effectively in desert climate and terrain to provide the highly mobile means of communications demanded by widely dispersed forces. However, desert terrain provides poor electrical ground, and counterpoises are needed to improve operation.

Techniques for Operations

For the best operation in the desert, radio antennas should be located on the highest terrain available. Transmitters using whip antennas in the desert will lose one-fifth to one-third of their normal range because of the poor electrical grounding characteristics of desert terrain. For this reason, it is important to use complete antenna systems such as horizontal dipoles and vertical antennas with adequate counterpoises.

Equipment Considerations

Some SCRs automatically switch on their second blower fan if their internal temperature rises too high. Normally, this happens only in temperate climates when the radios are transmitting. This may disturb Marines unaccustomed to radio operation in the desert environment. Operation of the second fan, however, is quite normal. RF power amplifiers used in AM and SSB sets are liable to overheat severely and burn out. They should be turned on only when necessary (signal reception is not affected). Since the RF power amplifiers take approximately 90 seconds to reach the operating mode, the standing operating procedure (SOP) of units using the equipment should allow for delays in replying.

Dust affects communications equipment such as SSB/AM RF power amplifiers. Dust covers should be used whenever possible. Some receiver-transmitter units have ventilating ports and channels that can get clogged with dust. These must be checked regularly and kept clean to prevent overheating.

Batteries. Wet cell batteries do not hold their charge efficiently in intense heat. Electrolyte evaporates rapidly and should be checked weekly (more often, if warranted). Add distilled water as needed. Extra containers of distilled water should be carried in the vehicle. Maintenance of vehicle batteries, beyond adding water, must be done only by authorized motor-transport personnel according to applicable Marine Corps Orders and SOPs. Dry battery supplies must be increased, since hot weather causes batteries to fail more rapidly.

Electrical Insulation. Wind-blown sand and grit will damage electrical wire insulation over a period of time. All cables that are likely to be damaged should be protected with tape before insulation becomes worn. Sand will also find its way into parts of items such as "spaghetti cord" plugs, either preventing electrical contact or making it impossible to join the plugs. Carry a brush, such as an old toothbrush, and use it to clean such items before they are joined.

Condensation. In deserts with relatively high dew levels and high humidity, overnight condensation can occur wherever surfaces (such as metals exposed to air) are cooler than the air temperature. This condensation can affect electrical plugs, jacks, and connectors. All connectors likely to be affected by condensation should be taped to prevent moisture from contaminating the contacts. Plugs should be dried before inserting them into equipment jacks. Excessive moisture or dew should be dried from antenna connectors to prevent arcing.

Static Electricity. Static electricity is prevalent in the desert. It is caused by many factors, e.g., wind-blown dust particles. Extremely low humidity contributes to static discharges between charged particles. Poor grounding conditions exacerbate the problem. Be sure to tape all sharp edges (tips) of antennas to cut down on wind-caused static discharges and the accompanying noise. If you are operating from a fixed position,

ensure that equipment is properly grounded. Since static-caused noise diminishes with an increase in frequency, use the highest frequencies that are available and authorized.

Maintenance Improvement

In desert areas, the maintenance of SCRs becomes more difficult because of the large amounts of sand, dust, or dirt that enter the equipment. Radios equipped with servomechanisms are particularly affected. To reduce maintenance downtime, keep the radios in dustproof containers as much as possible. It is also important to keep air vent filters clean to allow cool air to circulate to prevent overheating. Preventive maintenance checks should be made frequently. Also, keep a close check on lubricated parts of the equipment. If dust and dirt mix with the lubricants, moving parts may be damaged.

OPERATIONS IN JUNGLE AREAS

Capabilities and Limitations

SCR communications in jungle areas must be carefully planned because the dense jungle growth significantly reduces the range of radio transmission. However, since SCR can be deployed in many configurations, especially manpacked, it is a valuable communications asset. Mobility is also an advantage of SCR. The capabilities and limitations of SCR must be carefully considered when used by forces in a jungle environment.

Climate and density of jungle growth limits SCR communications in jungle areas. The hot and humid climate increases the maintenance problems of keeping equipment operable. Thick jungle growth acts as a vertically polarized absorbing screen for RF energy that reduces transmission range. Therefore, increased emphasis on maintenance and antenna siting is necessary when operating in jungle areas.

Techniques for Operations

The main problem in establishing SCR communications in jungle areas is the siting of the antenna.

Apply the following techniques to improve communications in the jungle:

- Antennas should be located in clearings on the edge farthest from the distant station and as high as possible.
- Antenna cables and connectors should be kept off the ground to lessen the effects of moisture, fungus, and insects. This also applies to all power and telephone cables.
- Complete antenna systems, such as ground planes and dipoles, are more effective than fractional wavelength whip antennas.
- Vegetation must be cleared from antenna sites. If an antenna touches any foliage, especially wet foliage, the signal will be grounded.
- Vegetation, particularly when wet, acts like a vertically polarized screen and absorbs much of a vertically polarized signal. Horizontally polarized antennas are preferred to vertically polarized antennas.

Maintenance Improvement

Because of moisture and fungus, the maintenance of SCR in tropical climates is more difficult than in temperate climates. The high relative humidity causes condensation to form on the equipment and encourages the growth of fungus. Operators and maintenance personnel should check the appropriate TMs for any special maintenance requirements. Some techniques for improving maintenance in jungle areas are—

- Keep the equipment as dry as possible and in lighted areas to retard fungus growth.
- Keep all air vents clear of obstructions so air can circulate to cool and dry the equipment.
- Keep connectors, cables, and bare metal parts as free of fungus growth as possible. Use moisture fungusproofing paint (MFP) to protect equipment after repairs are made or when equipment is damaged or scratched.

High Frequency Expedient Antennas

Dismounted patrols and units of company size and below can greatly improve their ability to communicate in the jungle by using expedient antennas. While moving, they are generally restricted to using the short and long antennas which come with the radios. However, when they are not moving, these expedient antennas will allow them to broadcast farther and receive more clearly.

Note: An antenna that is not "tuned" or "cut" to the operating frequency is not as effective as the whips that are supplied with the radio.

Circuits inside the radio "load" the whips properly so that they are "tuned" to give maximum output. Whips are not as effective as a tuned doublet or tuned ground-plane, but the doublet or ground-plane must be tuned to the operating frequency.

OPERATIONS IN A COLD WEATHER ENVIRONMENT

Capabilities and Limitations

SCR equipment has certain capabilities and limitations that must be carefully considered when operating in extremely cold areas. However, in spite of significant limitations, SCR is the normal means of communications in such areas.

One of the most important capabilities of SCR in cold weather areas is its versatility. Vehicular-mounted radios can be moved relatively easily to almost any point where it is possible to install a command headquarters. Smaller, manpacked radios can be carried to any point accessible by foot or aircraft.

A limitation on radio communications that radio operators must expect in extremely cold areas is interference by ionospheric disturbances. These disturbances, known as ionospheric storms, have a definite degrading effect on sky wave propagation. Moreover, either the storms or the auroral (e.g., Northern Lights) activity can cause complete failure of radio communications. Some frequencies may be blocked out completely by static for extended periods of time during storm activity.

Fading, caused by changes in the density and height of the ionosphere, can also occur and may last from minutes to weeks. The occurrence of these disturbances is difficult to predict. When they occur, the use of alternate frequencies and a greater reliance on FM or other means of communications are required.

Techniques for Operations

Whenever possible, SCR for tactical operations in cold weather areas should be installed in vehicles to reduce the problem of transportation and shelter for operators. This will also help solve some of the grounding and antenna installation problems caused by the climate.

Because of permafrost and deep snow, it is difficult to establish good electrical grounding in extremely cold areas. The conductivity of frozen ground is often too low to provide good ground wave propagation. To improve ground wave operation, use a counterpoise to offset the degrading effects of poor electrical ground conductivity. Remember to install a counterpoise high enough above the ground so that it will not be covered by snow.

In general, antenna installation in arcticlike areas presents no serious difficulties. However, installing some antennas may take longer because of adverse working conditions. A few tips for installing antennas in extremely cold areas are—

- Mast sections and antenna cables must be handled carefully since they become brittle in very low temperatures.
- Antenna cables should be constructed overhead to prevent damage from heavy snow and frost, whenever possible. Nylon rope guys, if available, should be used in preference to cotton or hemp because nylon ropes do not readily absorb moisture and are less likely to freeze and break.
- Antennas should have extra guy wires, supports, and anchor stakes to withstand heavy ice and wind loading.

Some Marine Corps radios that are adjusted to a particular frequency in a relatively warm place may drift off frequency when exposed to

extreme cold. Low battery voltage can also cause frequency drift. When possible, allow a radio to warm up several minutes before placing it into operation. Since extreme cold tends to lower output voltage of a dry battery, try warming the battery with body heat before operating the radio set. This minimizes frequency drift. Flakes or pellets of highly electrically charged snow are sometimes experienced in northern regions. When these particles strike the antenna, the resulting electrical discharge causes a high-pitched static roar that can blanket all frequencies. To overcome this static, antenna elements can be covered with polystyrene tape and shellac.

Maintenance Improvement

The maintenance of SCR equipment in extreme cold presents many difficulties. Radios must be protected from blowing snow, since snow will freeze to dials and knobs and blow into the wiring to cause shorts and grounds. Cords and cables must be handled carefully since they may lose their flexibility in extreme cold. All radio equipment and power units must be properly winterized. Check the appropriate technical manual (TM) for winterization procedures. A few tips for maintenance in arctic areas are discussed in the following paragraphs.

Power Units. As the temperature goes down, it becomes increasingly difficult to operate and maintain generators. They should be protected as much as possible from the weather.

Batteries. The effect of cold weather on wet and dry cell batteries depends upon the type and kind of battery, the load on the battery, the particular use of the battery, and the degree of exposure to cold temperatures.

Shock Damage. Damage may occur to vehicular SCR by the jolting of the vehicle. Most synthetic rubber shock mounts become stiff and brittle in extreme cold and fail to cushion equipment. Check the shock mounts frequently and change them, as required.

Winterization. Check the TMs for the SCR and power source to see if there are special precautions for operation in extremely cold climates.

For example, normal lubricants may solidify and permit damage or malfunctions. They must be replaced with the recommended arctic lubricants.

Microphones. Moisture from your breath may freeze on the perforated cover plate of your microphone. Use standard microphone covers to prevent this. If standard covers are not available, improvise a suitable cover from rubber or cellophane membranes or from rayon or nylon cloth.

Breathing and Sweating. A SCR generates heat when it is operated. When it is turned off, the air inside cools and contracts and draws cold air into the set from the outside. This is called breathing. When a radio breathes, and the still-hot parts come in contact with subzero air, the glass, plastic, and ceramic parts of the set may cool too rapidly and break.

When cold equipment is brought suddenly into contact with warm air, moisture will condense on the equipment parts. This is called sweating. Before cold equipment is brought into a heated area, it should be wrapped in a blanket or parka to ensure that it will warm gradually to reduce sweating. Equipment must be thoroughly dry before it is taken back out into the cold air or the moisture will freeze.

Vehicular-Mounted Radios. These radios present special problems during winter operations because of their continuous exposure to the elements. Proper starting procedures must be observed. The radio's power switch must be off prior to starting the vehicle; this is a particularly critical requirement when vehicles are slave started. If the radio is cold soaked from prolonged shutdown, frost may have collected inside the radio and could cause circuit arcing. Hence, time should be allowed for the vehicle heater to warm the radio sufficiently that any frost collected within the radio has a chance to thaw. This may take up to an hour. Once the radio has been turned on, it should warm up for approximately 15 minutes before transmitting or changing frequencies. This allows components to stabilize. If a vehicle is operated at a low idle with radios, heater, and lights on, the batteries may run down. Before increasing engine revolutions per minute to charge the batteries, radios should be turned off to avoid an excessive power surge. A light coat of silicon compound on

antenna mast connections helps to keep them from freezing together and becoming hard to dismantle.

OPERATIONS IN MOUNTAINOUS AREAS

Capabilities and Limitations

Operation of SCRs in mountainous areas has many of the same problems as in northern or cold weather areas. Also, the mountainous terrain makes the selection of transmission sites a critical task. In addition, the terrain restrictions encountered frequently make radio relay stations necessary for good communications.

Maintenance Improvement

Because of terrain obstacles, SCR transmissions will frequently have to be by line of sight. Also, the ground in mountainous areas is often a poor electrical conductor. Thus, a complete antenna system, such as a dipole or ground-plane antenna with a counterpoise, should be used. The maintenance procedures required in mountainous areas are very often the same as maintenance in northern or cold weather areas. The varied or seasonal temperature and climatic conditions in mountainous areas make flexible maintenance planning a necessity.

OPERATIONS IN SPECIAL ENVIRONMENTS

Urbanized Terrain

SCR communications in urbanized terrain poses special problems. Some problems are similar to those encountered in mountainous areas. There are problems of obstacles blocking transmission paths. There is the problem of poor electrical conductivity because of pavement surfaces. There is also the problem of commercial power-line interference. VHF radios are not as effective in urbanized terrain as they are in some other areas. The power output and operating frequencies of these VHF radios require a line of sight between antennas. Line of sight at street level is not always possible in built-up areas.

HF radios do not require or rely on line of sight as much as VHF radios because operating frequencies are lower, and power output is greater. The problem is that HF radios are not organic to small units. To overcome this, the VHF signals must be retransmitted.

Retransmission stations in aerial platforms can provide the most effective means if they are available. Organic retransmission is more likely to be used. The antenna should be hidden or blended in with surroundings. This will help prevent the enemy from using it as a landmark to "home in" his artillery bombardment. Antennas can be concealed by water towers, existing civilian antennas, or steeples.

The following steps should also be taken within urbanized terrain:

- Park radio-equipped vehicles inside buildings for cover and concealment.
- Dismount radio equipment and install it inside buildings (in basement, if available).
- Place generators against buildings or under sheds to decrease noise and provide concealment (adequate ventilation must be provided to prevent heat buildup and subsequent failure of generator).

Nuclear, Biological, and Chemical Environment

One of the realities of fighting on the modern battlefield is the presence of nuclear weapons. The explosion of a nuclear weapon causes a tremendous blast, followed by intense heat and strong radiation. The ionization of the atmosphere by a nuclear explosion will have degrading effects on communications because of static and the disruption of the ionosphere.

Another effect of a nuclear explosion that is an even greater danger to radio communications is the electromagnetic pulse (EMP). EMP is a strong pulse of electromagnetic radiation, many times stronger than the static pulse generated by lightning. This pulse can enter the radio through the antenna system, power connections, and signal input connections. In the equipment, the pulse can break down circuit components such as transistors, diodes, and integrated circuits. It can melt capacitors, inductors, and transformers. EMP can destroy a radio.

Defensive measures against EMP call for proper maintenance, particularly the shielding of equipment. When the equipment is not in use, all antennas and cables should be removed to decrease the effect of EMP on the equipment. Effective grounding is necessary to reduce effect of EMP. EMP is a danger to SCR equipment, but contamination is a danger to Marines. Contamination from any portion of the nuclear, biological, and chemical (NBC) environment has adverse effects on both equipment and personnel.

(reverse blank)

Chapter 7

Electronic Warfare

Electronic warfare (EW) is the military action involving the use of electromagnetic energy (i.e., radio frequency waves) to attack personnel, facilities, or equipment with the intent of degrading, neutralizing, or destroying enemy combat capability. EW includes electronic attack (EA), electronic protection (EP), and electronic warfare support (ES).

EA includes actions taken to prevent or reduce the enemy's effective use of the electromagnetic spectrum and employment of weapons that use electromagnetic or directed energy. EP represents actions taken to protect personnel, facilities, and equipment from any effects of friendly or enemy employment of electronic warfare that degrade, neutralize, or destroy friendly combat capability. ES involves actions taken by, or under direct control of, an operational commander to search for, intercept, identify, and locate sources of intentional or unintentional radiated electromagnetic energy for the purpose of immediate threat recognition. Each radio operator must be aware of what the enemy will try to do. The enemy is well equipped to conduct EW, and the different techniques the enemy uses have specific purposes in the enemy's EW effort.

ELECTRONIC ATTACK TECHNIQUES

Enemy forces employ a large number of radio direction finder (RDF) sets and communications intelligence (COMINT) analysts to exploit friendly use of the electromagnetic spectrum. The enemy's goal is to locate and destroy as many command and control, fire support, and intelligence sites as possible during the first critical phase of the battle. When the enemy locates sites that the enemy cannot or does not want to destroy, these sites become prime targets for imitative electronic deception (IED) or jamming. Imitative electronic deception is the enemy's use of a compatible radio and a language expert to enter a friendly radio net. The enemy IED experts are very good at their jobs. If they are permitted to enter into a net, they will create much confusion for friendly forces.

Jamming is an effective way to disrupt control of the battle. All it takes is a transmitter, tuned to your frequency, with the same type of modulation and with enough power output to override the signal at your receiver.

There are many types of jamming signals that may be used against a radio operator. Some are very difficult to detect and some are impossible to detect. For this reason, an operator must always be alert to the probability of jamming and react accordingly when the radio has been silent for an inordinate amount of time. The radio operator should also be able to quickly identify the various types of jamming signals. These include—

- Random noise.
- Random pulse.
- Stepped tones.
- Wobbler.
- Random keyed modulated continuous wave.
- Tone.
- Rotary.
- Pulse.
- Spark.
- Recorded Sounds.
- Gulls.
- Sweep-through.

Capture Effect and Jamming Techniques

An inherent characteristic in FM communications is that a given station transmitting a signal will capture those receivers on the same frequency and in range for the receiver to detect the signal. This is the basis for netted communications for VHF FM radios. This FM capture effect is undesirable when receivers in a net are "captured" by a transmitter not in that net. This could be friendly interference or enemy interference. Friendly interference is usually unintentional whereas enemy interference is usually intentional.

Obvious Jamming

Radio operators are mostly aware of obvious interference (e.g., jamming) by an enemy, such as stepped tones (e.g., bagpipes), random-keyed Morse Code, pulses, and recorded sounds. The purpose of this type of jamming is to block out reception of friendly transmitted signals and to cause a nuisance to the receiving operator. An operator can usually detect when the enemy is using this type of jamming.

Subtle Jamming

This type of jamming is not obvious at all. With subtle jamming, no sound is heard from the receiver. The radio does not receive incoming friendly signals, yet everything seems normal to the operator.

Operator Actions

Radio operators must be able to determine whether or not their radios are being jammed. This is not always easy. Threat jammers may employ obvious or subtle jamming techniques. These techniques may consist of powerful unmodulated or noise-modulated carrier signals transmitted to the operator's receiver. Unmodulated jamming signals are characterized by a lack of noise. Noise-modulated jamming signals are characterized by obvious interference noises. If radio operators suspect that their radios are the targets of threat jamming, the following procedures will help them to make this determination.

Meaconing, Intrusion, Jamming, and Interference Report

If the radio operator suspects jamming or enemy intrusion on the net, then the radio operator should report it immediately to higher headquarters. Such information is vital for the protection and defense of radio communications.

Field meaconing, intrusion, jamming, and interference (MIJI) reports serve two purposes. First, initial MIJI reports facilitate battlefield evaluations of the enemy's actions or intentions and provide data for tactical countermeasures, as appropriate. Second, complete and accurate follow-up reports ensure MIJI incidents are documented and evaluated on a

national level, thus providing data for a continuing study of foreign electronic warfare capabilities and activities.

MIJI reports may be transmitted over nonsecure electronic means when secure communications are not available; however, the textual content of the MIJI report will be secured by an off-line (i.e., manual) system. Reports will be prepared in the format outlined in the following paragraphs. Brevity numbers pertinent to specific line item information are provided for some items. These brevity numbers must be encoded in the numeral cipher or authentication system prior to transmission. The two types of field MIJI reports are—

- MIJI 1—an abbreviated initial report containing only those items of information necessary to inform headquarters of the incident and enable them to initiate evaluatory or retaliatory actions as appropriate.
- MIJI 2—consists of 40 lines and is completed by higher headquarters.

The MIJI 1 Report. This report is forwarded through the chain of command to the combat operations center by the operator who is experiencing the MIJI incident. A separate report is submitted for each MIJI incident. The MIJI report includes—

- Item 1—type report. When being transmitted over nonsecure communications means, the numerals 022 are encrypted as Item 1 of the MIJI 1 report. When being transmitted over secure communications means, the term MIJI 1 is used as Item 1 of the MIJI 1 report.
- Item 2—type MIJI incident. When being transmitted over nonsecure communications means, the appropriate numeral preceding one of the items below is encrypted as Item 2 of the MIJI 1 report. When being transmitted over secure communications means, the appropriate term below is used as Item 2 of the MIJI 1 report.

  1 Meaconing
  2 Intrusion
  3 Jamming
  4 Interference

- Item 3—type of equipment affected. When being transmitted over nonsecure communications means, the appropriate numeral preceding one of the terms below is encrypted as Item 3 of the MIJI 1 report. When being transmitted over secure communications means, the appropriate term below is used as Item 3 of the MIJI 1 report.

  1 Radio
  2 Radar
  3 Navigational aid
  4 Satellite
  5 Electro-optics

- Item 4—Frequency or channel affected. When being transmitted over nonsecure communications means, the frequency or channel affected by the MIJI incident is encrypted as Item 4 of the MIJI 1 report. When being transmitted over secure communications means, the frequency or channel affected by the MIJI incident is Item 4 of the MIJI 1 report.
- Item 5—victim designation and call sign of affected station operator. The complete call sign of the affected station operator is Item 5 of the MIJI 1 report over both secure and nonsecure communications means.
- Item 6—coordinates of the affected station. When being transmitted over nonsecure communications means, the complete grid coordinates of the affected station are encrypted as Item 6 of the MIJI 1 report. When being transmitted over secure communications means, the complete grid coordinates of the affected station are Item 6 of the MIJI 1 report.

The MIJI 2 Report. This is a complete report containing all details of the MIJI incident. Due to the number of items which require encryption when the report is transmitted over a nonsecure circuit, it is recommended that the report be delivered by messenger whenever possible. The higher headquarters' operations officer, intelligence officer, or the electronic warfare officer is responsible for ensuring that a complete message report of the incident is submitted to the Joint Command and Control Warfare Center (JC2WC) within 24 hours of the incident.

ELECTRONIC PROTECTION TECHNIQUES

Communications security (COMSEC) is an integral part of electronic protection. COMSEC is the protection resulting from all measures designed to deny unauthorized persons information of value that might be derived from the possession and study of telecommunications or to mislead unauthorized persons in their interpretation of the results of such possession and study. COMSEC includes transmission, cryptographic, emission, and physical security.

The goal of COMSEC is to protect friendly communications from enemy exploitation while ensuring unimpeded use of the electromagnetic spectrum. The organization must be able to employ communications equipment effectively in the face of enemy efforts.

COMSEC requirements must be integrated into communications systems planning and must focus on providing secure communications without impairing reliability or responsiveness. Modern communications equipment includes features such as an integrated encryption capability and frequency hopping capability, which contribute to communications protection. However, the security of our communications depends on the proper operation of communications equipment and adherence to proper procedures.

Transmission security

Transmission security (TRANSEC) is that component of COMSEC that results from all measures designed to protect transmissions from interception and exploitation by means other than cryptoanalysis. A message transmitted in the clear is the enemy's greatest source of information. After the enemy has intercepted your radio transmission, the enemy's language specialists will extract all possible intelligence from it. The enemy hopes to learn essential elements of friendly information (EEFI). Critical information that must be protected can be remembered by the key words SELDOM UP.

Each letter indicates a class of information as follows:

- Strength—number of personnel, size of unit.
- Equipment—type, quantity, condition.
- Logistics—procedure for resupply, depots.
- Disposition—were, what positions, map coordinates.
- Organization—how, what, chain of command, forces structure.
- Movement and morale—where, how, when and good or bad.
- Units—type, designation.
- Personalities—who, where.

Using TRANSEC is absolutely essential for the radio operator. When the radio must be used, keep transmission time to an absolute minimum (20 seconds absolute maximum: 15 seconds maximum preferred); preplan your messages to avoid compromising any essential element of information. If you must send EEFI items, use brevity lists, if possible, and also encrypt the message. These measures decrease your transmission, help prevent RDF, and deny the enemy valuable information. Included under transmission security are the authentication procedures that must be followed to protect against the enemy's IED. Every radio operator must be aware of the dangers of and guard against IED.

Strict radio discipline and adherence to authorized procedures are key to ensuring TRANSEC over SCR networks. SINCGARS radios should be operated in a frequency hopping mode to provide maximum protection against enemy EW capabilities. Other TRANSEC measures include—

- Well-trained operators thoroughly familiar with proper communications procedures and equipment operation. (This includes all Marines who may operate SCR, not just CIS personnel.)
- Avoidance of unauthorized transmission and testing and maximum use of data networks to minimize transmission time and opportunity for enemy direction finding.
- Use of transmitter, antenna, and power combinations that produce minimum wave propagation and emission intensity consistent with reliable communications.

- Strict adherence to authorized frequencies.
- Use of authentication systems to protect against imitative deception on nonsecure nets.
- Use of changing call signs and frequencies on nonsecure nets.
- Prompt response to and reporting of enemy jamming. (Operators should continue to operate on assigned frequencies in a secure mode, unless otherwise directed by a competent authority, and should attempt to work through the interference.)
- Strict adherence to all emission control (EMCON) restrictions and observance of radio silence.
- Use of communications means that do not radiate in the electromagnetic spectrum such as messengers, visual and sound signaling, and local wire loops.
- Use of terrain masking to shield transmission systems from enemy EW systems.
- Remoting of transmitters and avoiding the clustering of antennas.

Cryptosecurity

Cryptosecurity deals with codes, key lists, and communications security devices. This is the third line of defense for the radio operator. If the radio operator uses a security device on the radio, the enemy will not get anything for the language specialists to work on. However, do not get a false sense of security. The need for emission control and transmission security still exists—probably more so—because, if the enemy can't get information, the enemy might attempt to destroy or jam your station. Also, it is very important for all radio operators to use only authorized codes and to realize that using homemade codes is dangerous. Homemade codes offer no protection at all. Their use is not authorized and is a serious violation of security.

This also includes trying to "talk around" a classified or sensitive piece of information. The enemy intelligence personnel are not fools, and trying something like "talking around" critical information does more harm than good. If critical information must be transmitted, it should be encrypted or sent by secure means. In a situation when it is not possible to send by a secure means or to encrypt a message that must be sent, the

possibility of what friendly forces will lose against what the enemy could gain must be weighed. Other factors, such as how fast the enemy could react to the information and what delaying the message for encryption could mean, must also be considered.

Emission Security

Emission security (TEMPEST) is the component of COMSEC that results from all measures taken to deny unauthorized persons information of value that might be derived from interception and analysis of compromising emanations from cryptosecurity equipment and telecommunications systems. The operation of communications and information systems may result in unintentional electromagnetic emissions. Although tactical equipment is designed to reduce the possibility of such emissions, COTS equipment is not. Unintentional emissions are extremely susceptible to interception and analysis and may disclose classified information. Commanders must follow applicable regulations providing guidance on control and suppression of such emissions.

Physical Security

Physical security is the COMSEC component that results from all physical measures necessary to safeguard classified equipment, material, and documents from access or observation by unauthorized persons. The access to classified cryptographic information must be tightly controlled. When a commander or designated representative has determined that an individual has a need to know and is eligible for access, then access to classified cryptographic information will be formally authorized. The authorization process must include an introduction to the unique nature of cryptographic information, its unusual sensitivity, the special security regulations governing its handling and protection, and the penalties prescribed for its disclosure. Reportable violations include—

- Loss of material.
- Unauthorized viewing.
- Capture of individuals having access to COMSEC information.

Currently fielded COMSEC equipment is unclassified for external viewing when appropriate covers are in place and no keying material is visible. Consequently, the exposure of such equipment to casual viewing by uncleared personnel, whether by accident or as the result of operational necessity, does not constitute a reportable violation.

EP techniques are divided into two categories: preventive and remedial. Preventive EP are those procedures that can be used to avoid enemy EA attempts. Remedial EP apply to jamming only; there are no remedial measures once a unit has been intercepted, detected, or deceived.

ELECTRONIC WARFARE SUPPORT TECHNIQUES

Interception

The enemy is focused on intercepting your radio signal. To do this, all the enemy needs is a radio receiver that operates in the same mode and on the same frequency you are using to transmit. The mere fact that you are operating gives the enemy valuable information. It tells the enemy that you are in the area. By the number of stations operating on the same frequency, the enemy can estimate the size of the unit. If your net is operating in the clear, the enemy's language specialists can understand exactly what is said for even more information. When analyzing the traffic pattern, the enemy can figure out which station is the net control station (NCS) and identify the headquarters. Usually, in U.S. forces, the NCS is the radio used by the operations officer or section of the highest headquarters operating in the net. By further traffic analysis, the enemy can determine changes in the level of activity that could mean a movement or upcoming operation.

Radio Direction Finding

Interception is only one of the many dangers that the radio operator will face. After knowing friendly forces are in the area, the enemy will try to locate their position by using radio direction finding (RDF). A radio direction finder consists of a radio receiver, a directional antenna, and other specialized equipment. With RDF equipment, the approximate azimuth (i.e., bearing) to a transmitting radio can be determined. One

azimuth gives a general indication of direction. The intersection of two azimuths by different RDF stations is called a cut and gives a general indication of distance. The intersection of three or more azimuths is called a fix and gives a general location. The ideal fix is the exact intersection of three or more bearings. However, exact intersection is seldom achieved.

Terrain, weather, variations in radio wave propagation characteristics, the inherent RDF equipment, and operator inaccuracies, prevent an ideal fix. The fix that is obtained is called an actual fix. Although the actual fix may not be usable for immediate targeting purposes, it is more than enough for intelligence analysts to develop targeting data. Airborne direction finding is more accurate than ground-based direction finding but normally requires further analysis for targeting.

RDF ability to intercept electronics equipment emissions and determine a bearing depends on the power output of the targeting transmitter and its antenna radiation patterns. Experience indicates RDF accuracy of 500-meter (547-yard [yd]) circular error of probability (CEP) is considered a very good RDF fix. Normally, 50 percent of the CEPs are approximately 1,500 meters (1,640 yds) when the direction finder is located within 20 to 25 kilometers (12.4 to 15.5 mi) of the forward line of own troops (FLOT). Many threat forces will fire on a 1,500-meter (1,640-yd) CEP if they have sufficient massed artillery, and further analysis of terrain and radio intercept can reduce the target area or identify an important target.

(reverse blank)

Appendix A

Map Coordinates

Field coordinates are often expressed in universal transverse mercator grid coordinates and usually consist of 6-digit numbers. The typical map used by the radio operator is a 1 to 50,000 scale topographic map that has grid lines drawn on it, which are 1,000 meters (1 kilometer or klick) apart. (See fig. A-1.)

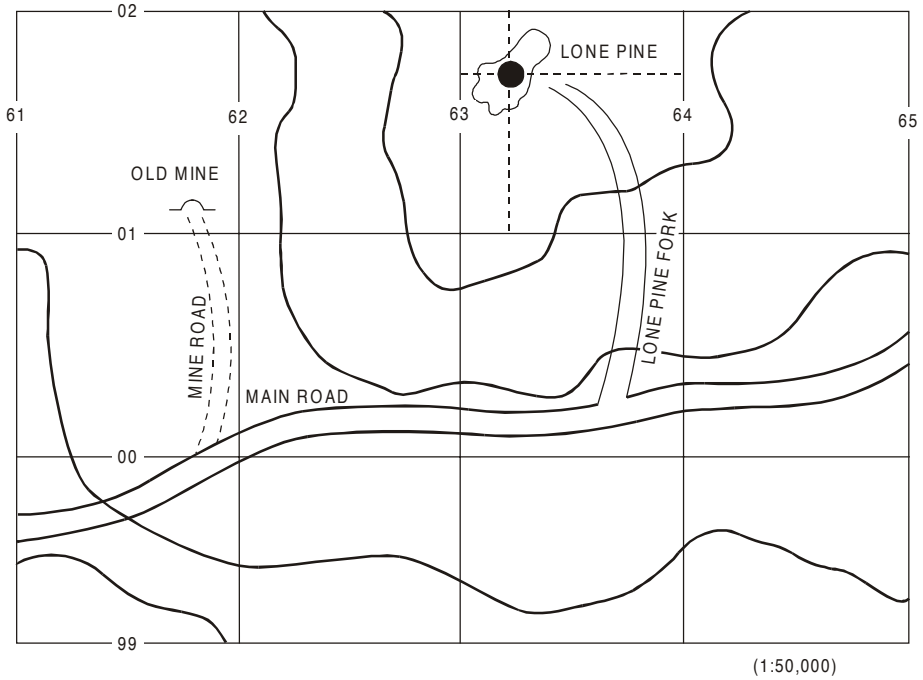

Figure A-1. Topographic Map.

To locate grid coordinate 632018, locate vertical line 63 (632018) in the figure and draw a vertical line 2/10 of the way (632018) between lines 63 and 64. Likewise, find horizontal line 01 (632018) and draw a

horizontal line 8/10 of the way (632018) between it and line 02. The two drawn lines intersect at Lone Pine.

Similarly, the intersection of the Lone Pine Fork with the Main Road in the figure would be represented as 638004, and the Old Mine would be 618012.

Although the use of the 6-digit number is generally sufficient for field use, a more exact coordinate will identify the 100,000 meter square and the grid zone designation to avoid confusion between different areas with identical grid line numbers.

A more detailed explanation of the complete coordinate may be found centered at the bottom of a 1 to 50,000 scale topographic map. The order in which the grids are read can be remembered by using the expression read-right-up.

Appendix B

Time Zones

The world is divided into 24 time zones, each one bearing a unique phonetic letter name (ROMEO, UNIFORM, etc.) or time zone number that must be applied to local time to arrive at the world standard time which is Coordinated Universal Time (UTC). This standard time is referred to in the Marine Corps as ZULU time. (See fig. B-1.) The time zones are roughly 15° apart in longitude.

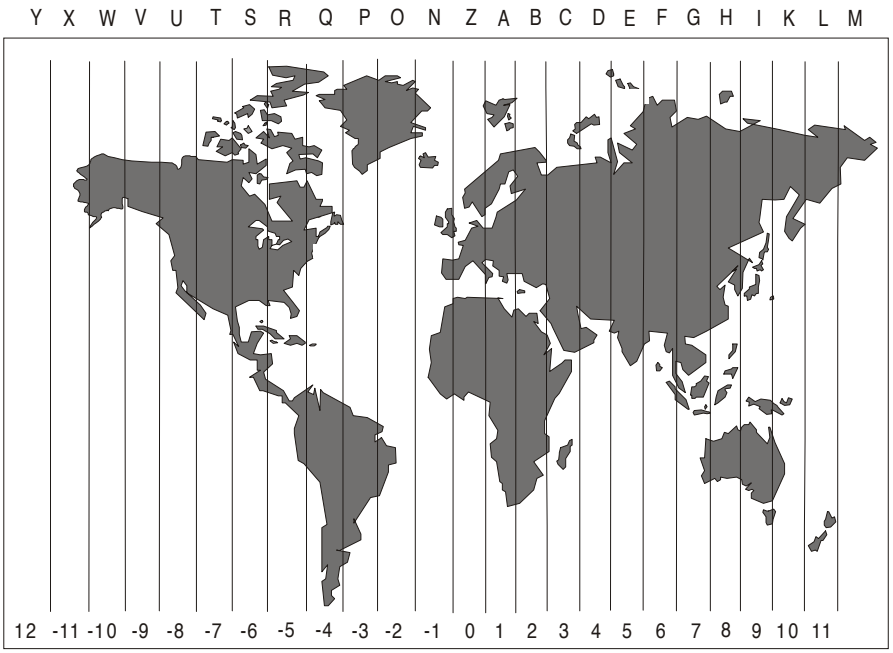

Figure B-1. Standard Time Zones of the World.

ZULU TIME = LOCAL TIME - TIME ZONE NUMBER.

LOCAL TIME = ZULU TIME + TIME ZONE NUMBER.

If a Marine is in the UNIFORM time zone, (also referred to as the PLUS 8 zone), 8 hours must be added to the local time to get ZULU time. (See table B-1.) On the other hand, in the ROMEO or PLUS 5 time zone, 1300 ZULU would equate to 0800 local. During the summer, however, if a Marine is located in an area where daylight savings time is observed, one hour must be subtracted from the time zone number; i.e., the PLUS 8 zone becomes the PLUS 7 zone for local time purposes.

Table B-1. CONUS Time Zones.

Civilian Time Zone	Military Time Zone	ZULU	Local Time	ZULU Time
EDT	QUEBEC	+4	0800 Q	1200 Z
EST CDT	ROMEO	+5	0700 R	1200 Z
CST MDT	SIERRA	+6	0600 S	1200 Z
MST PDT	TANGO	+7	0500 T	1200 Z
PST	UNIFORM	+8	0400 U	1200 Z

AUTODIN communications (i.e., worldwide) ZULU time should be used in all messages. Within the operational area, however, local time is usually used. To avoid confusion, the time zone should always be stated e.g., 1100 LOCAL or 1900 ZULU.

Appendix C

Prowords

Word or Phrase	Meaning
ALL AFTER	I refer to the portion of the message that follows.
ALL BEFORE	I refer to the portion of the message that precedes.
BREAK	I hereby indicate the separation of the text from other portions of the message. Or: I have completed the text of the message, signature follows, etc. (When break-in is permitted, receiving operator may interrupt the transmitting operator to request retransmission of a portion of a message. This proword is the interruption sign.)
CORRECTION	An error has been made in this transmission (or message indicated). The correct version is_____. That which follows is a corrected version in answer to your request for verification.
DISREGARD THIS TRANSMISSION	This transmission is in error. Disregard it. (This proword shall not be used to cancel any message that has been completely transmitted and for which receipt or acknowledgment has been received.)
DO NOT ANSWER	Stations called are not to answer this call receipt for this message, or otherwise to transmit in connection with this transmission. When this proword is employed, the transmission shall be ended with the proword *OUT*.

Word or Phrase	Meaning
EXECUTE	Carry out the purpose of the message or signal to which this applies. To be used only with the executive method.
EXECUTE TO FOLOW	Action on the message or signal which follows is to be carried out upon receipt of the proword *EXECUTE*. To be used only with the executive method.
EXEMPT	The addressee designations immediately following are exempted from the collective net call.
FIGURES	Numerals or numbers follow.
FLASH	Precedence *FLASH*.
FROM	The originator of this message is indicated by the address designation immediately following.
IMMEDIATE	Precedence *IMMEDIATE*.
INFO	The addressee designations immediately following are addressed for information.
I READBACK	The following is my response to your instructions to read back.
I SAY AGAIN	I am repeating transmission (or portion) indicated.
I SPELL	I shall spell the next word phonetically.
I VERIFY	The following message (or portion) has been verified at your request and is repeated. To be used only as a reply to verify.
MESSAGE FOLLOWS	A message which requires recording is about to follow. (Transmitted immediately after the call.)

Word or Phrase	Meaning
NUMBER	Station serial number.
OUT	This is the end of my transmission to you. No response is necessary.
OVER	This is the end of my transmission to you and a response is necessary. Go ahead and transmit.
PRIORITY	Precedence *PRIORITY.*
READ BACK	Repeat this entire transmission back to me exactly as received.
RELAY TO	Transmit this message to all addressees or to the address designations immediately following.
ROGER	I have received your last transmission satisfactorily.
ROUTINE	Precedence *ROUTINE*.
SAY AGAIN	Repeat all of your last transmission. Followed by identification data means: "Say again (portion indicated)." ("Repeat" is not used because it is the signal for naval gunfire and artillery to fire.)
SIGNALS FOLLOW	The groups which follow are taken from signal book. (This proword need not be used on nets primarily employed for conveying signals. It is intended for use when tactical signals are passed on nontactical nets.)
SILENCE, SILENCE, SILENCE	Cease transmission immediately. (Silence will be maintained until instructed to resume. When an authentication system is in force, transmissions imposing silence are to be authenticated.)

Word or Phrase	Meaning
SILENCE LIFTED	Resume normal transmissions. (Silence can be lifted only by the station imposing it or by higher authority. When an authentication system is in force, transmissions lifting silence are to be authenticated.)
SPEAK SLOWER	Your transmission is too fast. Reduce speed of transmission.
THAT IS CORRECT	You are correct, or what you have transmitted is correct.
THIS IS	This transmission is from the station whose designation immediately follows.
TIME	That which immediately follows is the time or date-time group of the message.
TO	The addressees whose designations immediately follow are to take action on this message.
UNKNOWN STATION	The identity of the station with whom I am attempting to establish communications is unknown.
VERIFY	Verify entire message (or portion indicated) with the originator and send correct version. To be used only at the discretion of or by the addressee to which the questioned message was directed.
WAIT	I must pause for a few seconds.
WAIT OUT	I must pause longer than a few seconds.

Word or Phrase	Meaning
WILCO	I have received your message, understand it, and will comply. (To be used only by the addressee. Since the meaning of ROGER is included in that of WILCO, the two prowords are never used together.)
WORD AFTER	I refer to the word that follows.
WORD BEFORE	I refer to the word that precedes.
WORDS TWICE	Communication is difficult. Transmit(ting) each phrase (or each code group) twice. This proword may be used as an order, request, or as information.
WRONG	Your last transmission was incorrect. The correct version is.

(reverse blank)

Appendix D

Phonetic Alphabet

Letter	Word	Pronunciation
A	ALFA	AL FAH
B	BRAVO	BRAH VOH
C	CHARLIE	CHAR LEE
D	DELTA	DELL TAH

Appendix F

Prosigns

Prosign	Meaning
AA	All after.
AB	All before.
AR	End of transmission. No receipt required.
AS	I must pause for a few seconds.
AS AR	I must pause longer than a few seconds. Will call you back.
B	More to follow.
BT	Break.
C	Correct.
DE	This is.
EEEEEEEE	Error.
EEEEEEEE AR	This message is in error. Disregard it.
F	Do not answer.
FM	From.
G	Repeat this entire transmission back to me.
GR	Group count.
GRNC	The groups in this message have not been counted.
HM HM HM	Emergency silence sign-silence.

IMI ..... Repeat.

INFO ..... The address designations immediately following are addressed for information only.

INT ..... Interrogative.

IX ..... Action on the message or signal which follows is to be carried out upon receipt of execute.

J ..... Verify with originator and repeat.

K ..... This is the end of my transmission to you and a response is necessary.

NR ..... Numerals or numbers follow.

O ..... Immediate precedence.

P ..... Priority precedence.

R ..... Routine precedence.

T ..... Relay to.

TO ..... Action addressee.

WA ..... Word after.

WB ..... Word before.

XMT ..... Exempt.

Y ..... Emergency command precedence.

Z ..... Flash precedence.

Appendix G

Instructions for Preparing Field Messages

1. Place the protector insert under the message blanks to limit the number of copies produced. Retain one copy in the book as a file copy. Classify cover in accordance with contents (see fig. G-1).

2. Use BLOCK CAPITAL letters for all entries except the signature. Use necessary punctuation.

3. To assign precedence and classification use table on the next page.

4. If a classified message is to be transmitted, secure voice or in the clear, check appropriate block.

5. Show organization originating message in FM (from) block.

6. Show organization(s) for whom the message is intended in the TO block.

7. Block labeled date-time group is for communication personnel only.

8. Draft the message in brief but clear terms.

9. Message drafters are responsible for all message drafting functions to include the use of brevity codes.

PRECEDENCE TABLE

Appendix I

Metric System Conversion Table

The basic unit of the metric system is the meter (m). The meter is 39.37 inches long. This is 3.37 inches longer than the English yard. Units that are multiples or fractional parts of the meter are designated by prefixes to the word "meter."

1 millimeter (mm) = 0.001 meter or 1/1000 meter
1 centimeter (cm)= 0.01 meter or 1/100 meter
1 decimeter (dm) = 0.1 meter of 1/10 meter
1 decameter (dkm) = 10 meters
1 hectometer (hm) = 100 meters
1 kilometer (km) = 1000 meters

The Metric Measurement in Most Common Use

10 millimeters = 1 centimeter
10 centimeters = 1 decimeter
10 decimeters = 1 meter
1000 meters = 1 kilometer

To Convert

Length	Multiply by
Inches to centimeters	2.54
Feet to meters	0.3048
Yards to meters	0.9144
Miles to kilometers	1.609
Millimeters to inches	0.03937
Centimeters to inches	0.3937
Decimeters to inches	3.937
Decimeters to feet	0.328
Meters to inches	39.37

Meters to feet	3.28
Meters to yards	1.0936
Decameters to feet	32.8
Hectometers to feet	328.1
Kilometers to feet	3281
Kilometers to yards	1093.6
Kilometers to miles	0.62

Examples:

To change 90 kilometers to miles: 90 x .62 = 55.8 miles
To change 90 kilometers to feet: 90 x 3281 = 295,290 feet
To change 50 yards to meters: 50 x 0.9144 = 45.72 meters

Appendix J

Authentication

Authentication systems are provided to prevent unauthorized enemy stations from entering friendly radio nets to disrupt or confuse operations. The only authentication systems authorized are those approved for use by the National Security Agency. If a special or emergency requirement arises, notify the CIS officer (G-6/S-6).

INSTRUCTIONS

There are two methods of authentication that are authorized for use: challenge and reply authentication and transmission authentication. The operational distinction is that challenge and reply requires two-way communications, whereas transmission authentication does not.

Challenge and Reply Authentication

Challenge and reply authentication will be used whenever possible. The called party will always make the first challenge. Besides validating the authenticity of the calling station, this practice prevents an enemy operator from entering a net to obtain correct authentication responses for use in another net. The party making the call may counterchallenge the called party using a different challenge.

Note: In challenge and reply authentication, only the station responding is verified. Do not accept a challenge as an authentication.

When a caller desires authentication, he must invite a challenge by stating that he is prepared to authenticate.

Another challenge should be made if an incorrect reply is received, if a standby is requested, or if an unusual delay occurs between challenge and reply.

Users will occasionally misauthenticate because of such problems as having the wrong system, misreading the table, etc. The challenging station should attempt to pinpoint the difficulty and then rechallenge.

Never give the challenge and reply in the same transmission (self authentication).

Transmission Authentication

Transmission authentication is used to validate the authenticity of the message when it is impossible or impractical to use challenge and reply authentication (see table J-1).

For Instructional Purposes Only

Table J-1. Sample AKAC-874 Transmission Authentication.

WHEN TO AUTHENTICATE

Transmission should be authenticated—

- When any station suspects imitative deception on any circuit; e.g., when contacting a station following one or more unsuccessful attempts to contact that station.
- When any station is challenged or requested to authenticate. This is not to be interpreted as requiring stations to break an imposed silence for the sole purpose of authenticating.
- When directing radio silence, listening silence, or requiring a station to break an imposed silence.
- When transmitting contact and amplifying reports in plain language.
- When transmitting operating instructions that affect the military situation; e.g., closing down a station or watch, changing frequency other than normal scheduled changes, directing establishment of a special communication guard, requesting artillery fire support, directing relocation of units, etc.
- When transmitting a plain language cancellation.
- When making initial radio contact or resuming contact after prolonged interruptions.
- When transmitting to a station that is under radio listening silence.
- When authorized to transmit a classified message in the clear.
- When forced, because of no response by the called station to send a message in the blind (transmission authentication).

Note: Authentication is not required when making initial contact after a scheduled call sign and frequency change since only bona fide stations will know their assigned call sign and frequency for the time period in use.

For detailed authentication instructions refer to the automated communications-electronics operations instructions.

Appendix K

International Morse Code

Dots and dashes are used in various distinctive combinations to represent the letters of the alphabet, the numerals from 0 to 9, and the prosigns (see fig K-1). The dots and dashes of the Morse Code are produced by keying a transmitter and causing it to transmit short and long signals. The dash is 3 times the length of the dot. The dots and dashes used for a letter are spaced from each other by a period of time equal in length to one dot. Letters are spaced from each other by a period of time equal to three dots. Words are spaced by a period of time equal to seven dots.

Appendix L

Frequency Prediction Means

Radio signals propagate from a transmitter to a receiver in different ways depending on the selected frequency of the radio. The two available resources for Marines to predict the best frequency to propagate over a given path are to use the Joint Spectrum Center (JSC) or the Marine Corps' system planning, engineering, and evaluation device (SPEED). See figure L-1 on page L-2.

JSC is a Department of Defense agency that is responsible for supplying the electromagnetic analysis to the uniformed services. Located in Annapolis, Maryland, JSC can perform a variety of propagation predictions on all ranges of frequencies. Once a quarter, JSC publishes a list of HF frequency predictions for selected paths that the Marine Corps has requested. A compilation of frequency predictions are held in the G-6 offices of the major subordinate commands within the Marine Corps.

The second method is SPEED. SPEED is computer software that allows communications system planners to do rapid analysis of radio signal propagation. The SPEED comes with electronic maps of the Earth which allow true line of sight data for the planners, as well as HF propagation prediction. SPEED is available down to the battalion level.

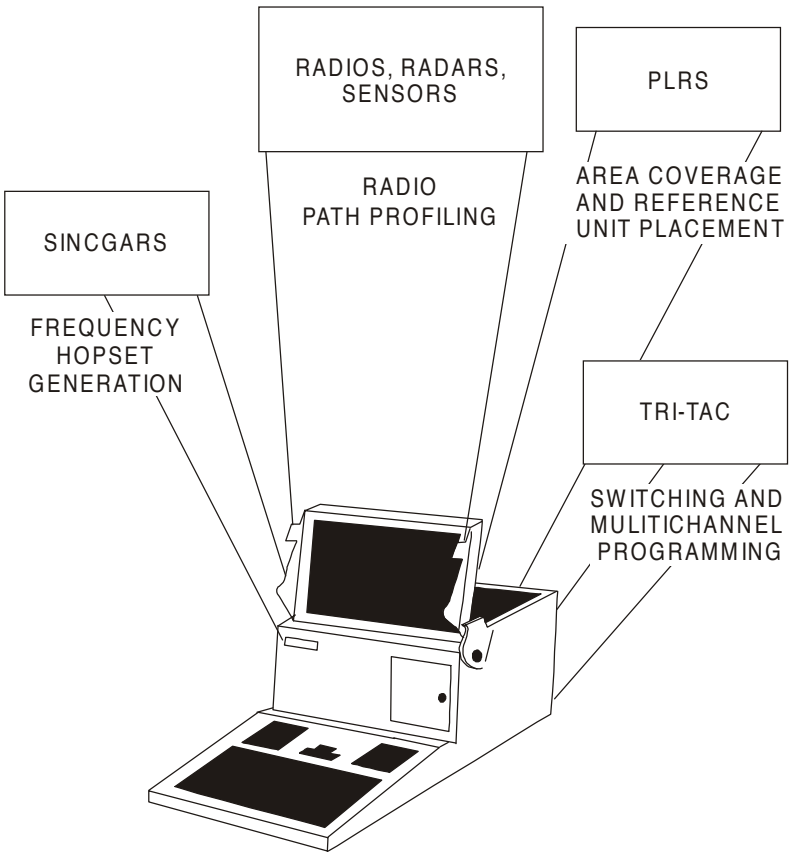

Figure L-1. SPEED.

Appendix M

Position and Navigation Systems

Global positioning system (GPS) and position location reporting system (PLRS) are new systems that radio operators may be required to operate.

GLOBAL POSITIONING SYSTEM

Global positioning system is a space-based navigation system designed to provide 24-hour continuous worldwide, all-weather precise position, and time measurement. The GPS consists of a space segment (satellite), control segment (monitors stations on Earth), and user segment (GPS receivers). The system operates by satellites sending out two signals on nonchanging frequencies. The GPS receiver receives the signals transmitted by the satellites and computes the users position. GPS (by being an all-weather, jam-resistant, continuous system) gives users highly accurate navigation; worldwide, three-dimensional position or location velocity; and time information. As a passive, receive-only system, GPS can be employed at the individual level in such nondescript terrain as jungles, mountain ranges, or deserts. (See fig. M-1 on page M-2.)

POSITION LOCATION REPORTING SYSTEM

PLRS is a system of UHF radios, signal and message processors, and user input and output devices configured as master stations and basic units that provide the user of the system with position navigation information and limited digital communications. PLRS works by the individual units in the network time sharing a single frequency band. As the master station records the arrival time of the signal bursts from each user unit at given locations, the range between sender and receiver can be computed. If units are beyond line of sight for the master station, then PLRS will automatically enable any user unit to serve as an automatic relay. The full PLRS performance can be provided over a 47- by 47-kilometer operating area. This operating area can be extended to a 300-by 300-kilometer area through the use of airborne relays provided by PLRS-equipped aircraft.

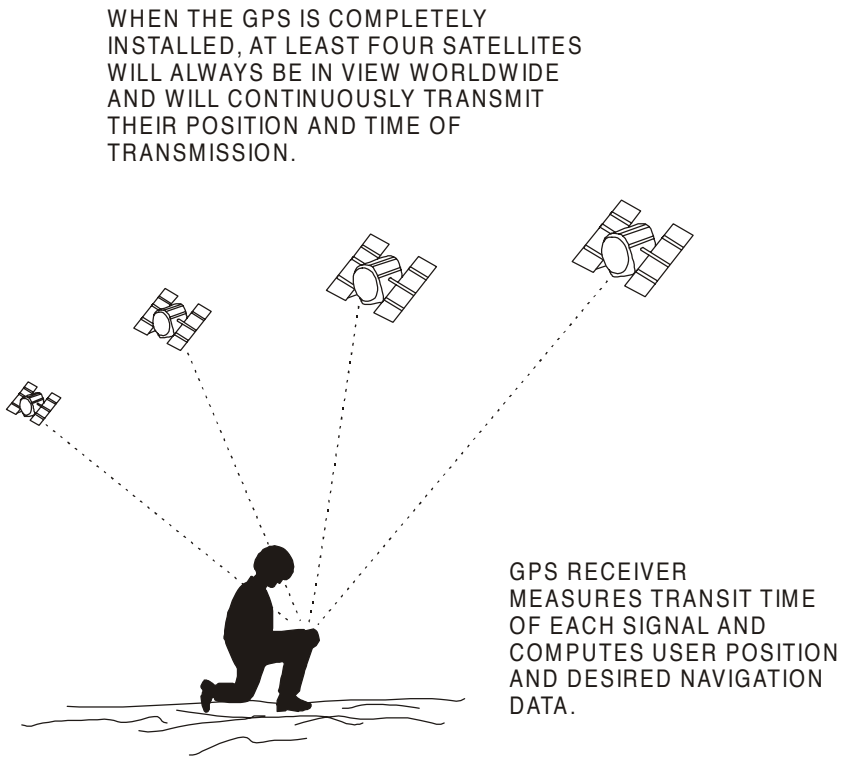

Figure M-1. Global Positioning System.

ENHANCED POSITION REPORTING SYSTEM

Enhanced position location reporting system (EPLRS) shares many characteristics with PLRS, but provides a significant increase in data communications capability over PLRS. Various data rates supporting a variety of broadcast and point-to-point modes are currently available. EPLRS will provide a dedicated data communications capability between regiment and battalion tactical data networks (TDNs) within the ground combat element, when fielded in FY-00. This network will also be extended to lower echelons throughout the MAGTF. EPLRS can also serve as a source for automated friendly position location information and navigation information in a hybrid community with PLRS, though data throughput is reduced.

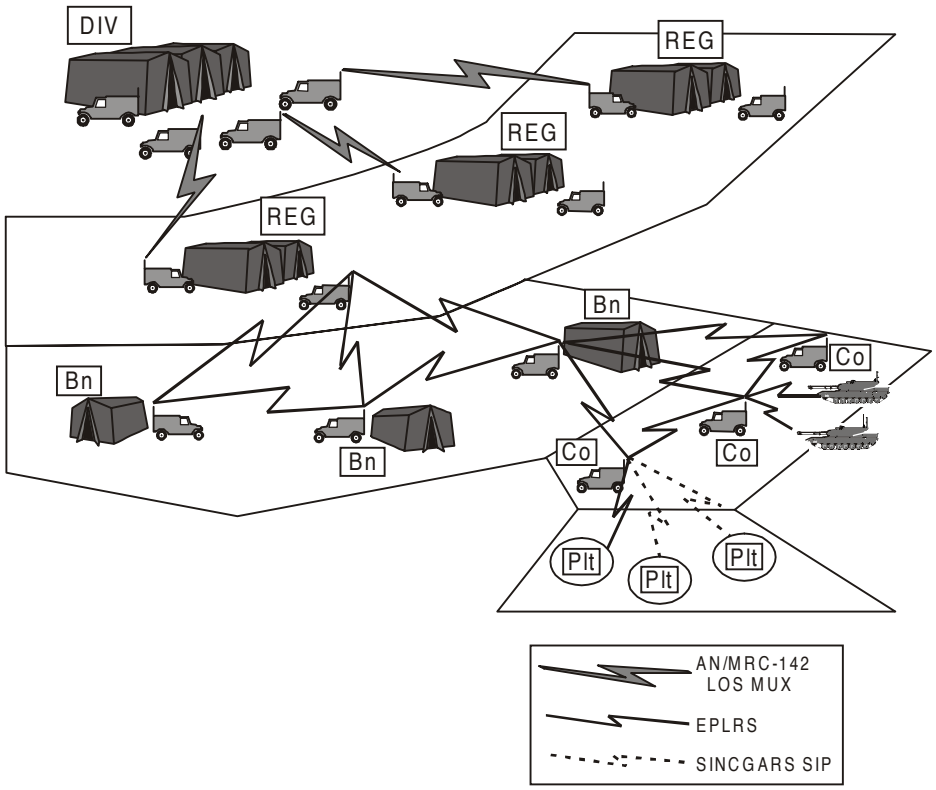

Figure M-2. EPLRS Concept of Employment.

Appendix O

Field Repair and Expedients

Section I. Antenna Repair

Antennas are sometimes broken or damaged, causing either a communications failure or poor communications. If a spare is available, replace the damaged antenna. When there is no spare, you may have to construct an emergency antenna. The following paragraphs are suggestions on repairing antennas and antenna supports and on constructing and adjusting emergency antennas.

REPAIR TECHNIQUES

Whip Antennas

When a whip antenna is broken into two sections, the portion of the antenna that is broken off can be connected to the portion attached to the base by joining the sections as shown in figure O-1 on page O-2. Use the method illustrated in figure O-1A, when both parts of the broken whip are available and usable. Use the method shown in figure O-1B when the portion of the whip that was broken off is lost, or when the whip is badly damaged. To restore the antenna to its original length, add a piece of wire that is nearly the same length as the missing part of the whip. Then, lash the pole support securely to both sections of the antenna. Clean the two antenna sections thoroughly to ensure good contact before connecting them to the pole support. If possible, solder the connections.

Wire Antennas

Emergency repair of a wire antenna may involve the repair or replacement of the wire used as the antenna or transmission line; or, the repair or replacement of the assembly used to support the antenna.

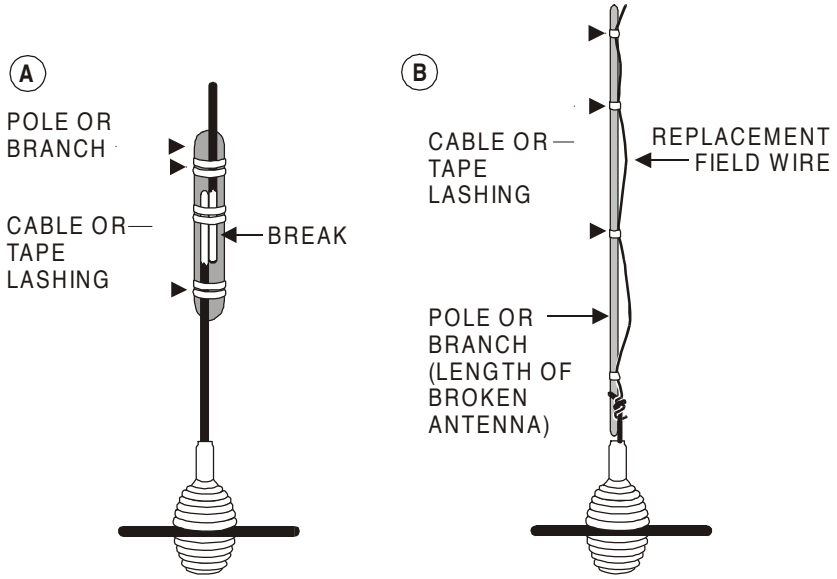

Figure O-1. Emergency Repair of Broken Whip.

When one or more wires of an antenna are broken, the antenna can be repaired by reconnecting the broken wires. To do this, lower the antenna to the ground, clean the ends of the wires, and twist the wires together. Whenever possible, solder the connection.

If the antenna is damaged beyond repair, construct a new one. Make sure that the lengths of the wires of the substitute antenna are the same length as the original.

Antenna supports may also require repair or replacement. A substitute item may be used in place of a damaged support and, if properly insulated, can be of any material of adequate strength. If the radiating element is not properly insulated, field antennas may be shorted to ground and rendered ineffective. Many commonly found items can be used as field expedient insulators. The best of these items are plastic or glass, to include plastic spoons, buttons, bottle necks, and plastic bags. Less effective than plastic or glass but better than no insulators at all are wood and rope, or both, in that order. The radiating element—the actual antenna wire—should touch only the antenna terminal and be physically

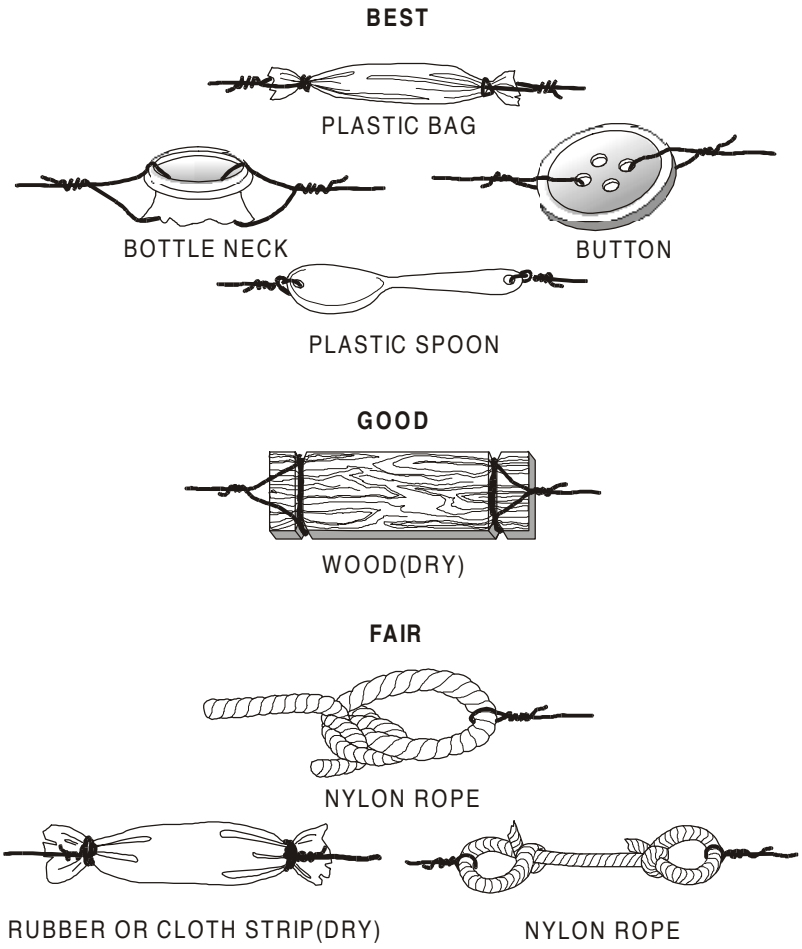

Figure O-2. Improvised Insulators.

separated from all other objects, other than the supporting insulator. Figure O-2 shows various emergency insulators.

Guys

Lines used to stabilize the supports for an antenna are called guys. These lines are usually made of wire, manila rope, or nylon rope. If a rope breaks, it may be repaired by tying the two broken ends together. If the rope is too short after the tie is made, it can be lengthened by adding another piece of dry wood or cloth. If a guy wire breaks, it can be

replaced with another piece of wire. Figure O-3 shows a method of repairing a guy line with a spoon.

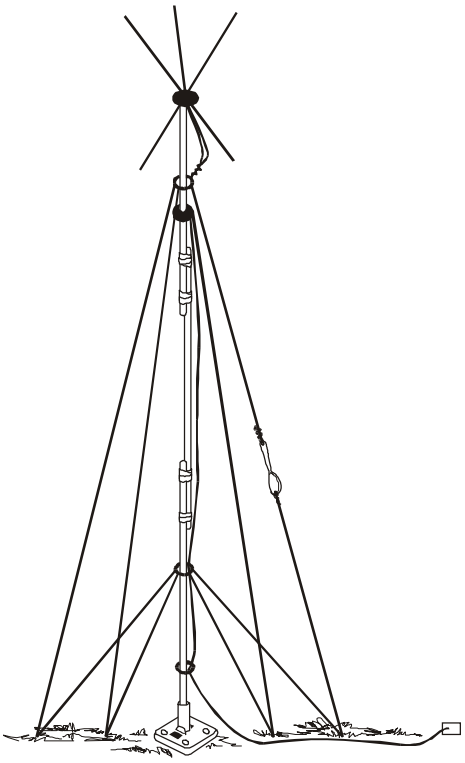

Figure O-3. Repaired Guy Lines and Masts.

Masts

Some antennas are supported by masts. If a mast breaks, it can be replaced with one of same length. If long poles are not available as replacements, short poles may be overlapped and lashed together with rope or wire to provide a pole of the required length. Figure O-3 shows a method of making an emergency repair to masts.

TIPS FOR CONSTRUCTION AND ADJUSTMENT

Constructing the Antenna

The best kinds of wire for antennas are copper and aluminum. In an emergency, however, use any type that is available.

The length of most antennas is critical. The emergency antenna should be the same length as the antenna it replaces.

Antennas supported by trees can usually survive heavy wind storms if the trunk of a tree or a strong branch is used as a support. To keep the antenna taut and to prevent it from breaking or stretching as the trees sway, attach a spring or old inner tube to one end of the antenna. Another technique is to pass a rope through a pulley or eyehook, attach the rope to the end of the antenna, and load the rope with a heavy weight to keep the antenna tightly drawn.

Guys used to hold antenna supports are made of rope or wire. To ensure that the guys made of wire will not affect the operation of the antenna, cut the wire into several short lengths and connect the pieces with insulators.

Adjusting the Antenna

An improvised antenna may change the performance of a radio set. Use the following methods to determine if the antenna is operating properly.

A distant station may be used to test the antenna. If the signal received from this station is strong, the antenna is operating satisfactorily. If the signal is weak, adjust the height and length of the antenna and the transmission line to receive the strongest signal at a given setting on the volume control of the receiver. This is the best method of tuning an antenna when transmission is dangerous or forbidden.

In some radio sets, the transmitter is used to adjust the antenna. First, set the controls of the transmitter in the proper position for normal operation; then, tune the system by adjusting the antenna height, the antenna

length, and the transmission line length to obtain the best transmission output.

Impedance-matching a load to its source is an important consideration in transmissions' systems. If the load and source are mismatched, part of the power is reflected back along the transmission line towards the source. This reflection not only prevents maximum power transfer, but can also be responsible for erroneous measurements of other parameters, or even cause circuit damage in high-power applications.

The power reflected from the load interferes with the incident (i.e., forward) power, causing standing waves of voltages and current to exist along the line. The ratio of standing-wave maxima to minima is directly related to the impedance mismatch of the load; therefore the standing-wave ratio (SWR) provides the means of determining impedance and mismatch.

WARNING

SERIOUS INJURY OR DEATH CAN RESULT FROM CONTACT WITH THE RADIATING ANTENNA OF A MEDIUM- OR HIGH-POWER TRANSMITTER. TURN THE TRANSMITTER OFF WHILE MAKING ADJUSTMENTS TO THE ANTENNA.

Section II. Field Expedient Antennas

SINCGARS VHF radios provide the primary means of communications for Marine Corps forces around the world. The SINCGARS radio operates in both single-channel and frequency hopping modes. It is important for CIS personnel to remember that when using the SINCGARS radio in the frequency hopping mode, field expedient VHF antennas should not be used. CIS personnel should only use the whip antenna or the OE-254 antenna when operating in the frequency hopping mode.

HIGH FREQUENCY, FIELD EXPEDIENT OMNIDIRECTIONAL ANTENNAS

Vertical antennas are omnidirectional; i.e., they transmit and receive equally well in all directions. Most manpack portable radios use a vertical whip antenna. A vertical antenna can be improvised by using a metal pipe or rod of the correct length, held erect by means of guys. The lower end of the antenna should be insulated from the ground by placing it on insulating material. A vertical antenna may also be a wire, supported by a tree or a wooden pole (see fig. O-4). For short, vertical

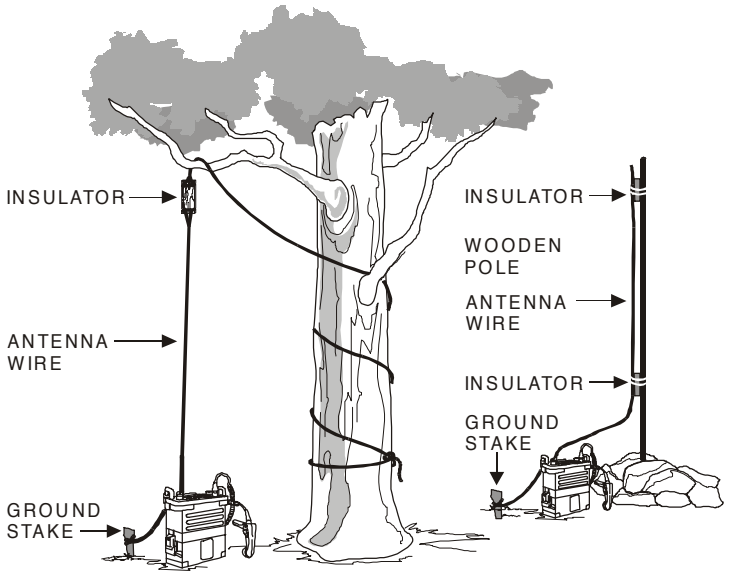

Figure O-4. Field Substitutes for Support of Vertical Wire Antennas.

antennas, the pole may be used without guys (if properly supported at the base). If the length of the vertical mast is not long enough to support the wire upright, it may be necessary to modify the connection at the top of the antenna.

End-Fed Half-Wave Antenna

An emergency, end-fed half-wave antenna can be constructed from available materials such as field wire, rope, and wooden insulators. The electrical length of this antenna is measured from the antenna terminal on the radio set to the far end of the antenna (see fig. O-5). Construct the antenna longer than necessary, then shorten it, as required, until best results are obtained. The ground terminal of the radio set should be connected to a good Earth ground for this antenna to function efficiently.

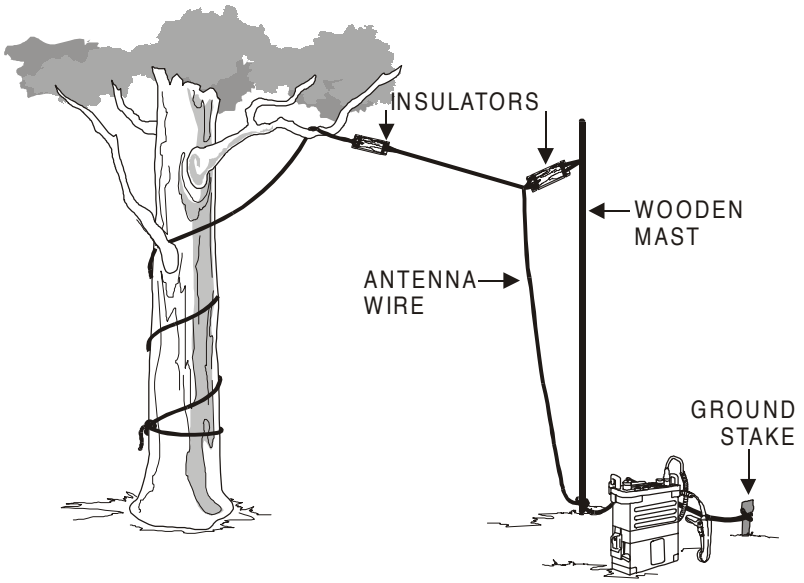

Figure O-5. End-Fed Half-Wave Antenna.

Center-Fed Doublet Antenna

The center-fed doublet is a half-wave antenna consisting of two, quarter-wavelength sections on each side of the center. Construction of an improvised doublet antenna for use with FM radios is shown in figure O-6.

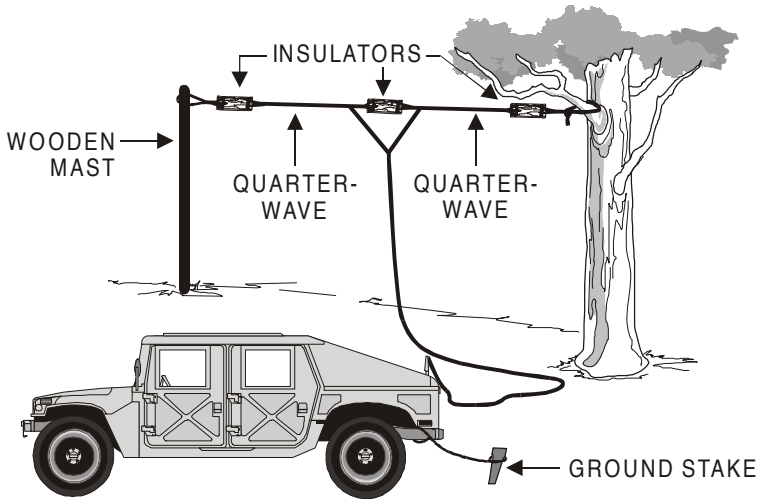

Figure O-6. Half-Wave Doublet Antenna.

Doublet antennas are directional broadside to their length, which makes the vertical doublet antenna essentially omnidirectional. This is because the radiation pattern is doughnut shaped. The horizontal doublet antenna is bidirectional.

The length of a half-wave antenna may be computed by using the formula in Chapter 4. Cut the wires as closely as possible to the correct length because the length of the antenna wires is important.

A transmission line is used for conducting electrical energy from one point to another, and it is used to transfer the output of a transmitter to an antenna. Although it is possible to connect an antenna directly to a transmitter, the antenna generally is located some distance away. In a vehicular installation, for example, the antenna is mounted outside, and the transmitter is inside the vehicle. A transmission line, therefore, is necessary as a connecting link.

Center-fed half-wave FM antennas can be supported entirely by pieces of wood. A horizontal antenna of this type is shown in figure O-7A; a vertical antenna in figure O-7B on page O-10. These antennas can be rotated to any position to obtain the best performance. If the antenna is erected vertically, the transmission line should be brought out horizontally from the antenna for a distance equal to at least one-half of the antenna's length before it is dropped down to the radio set.

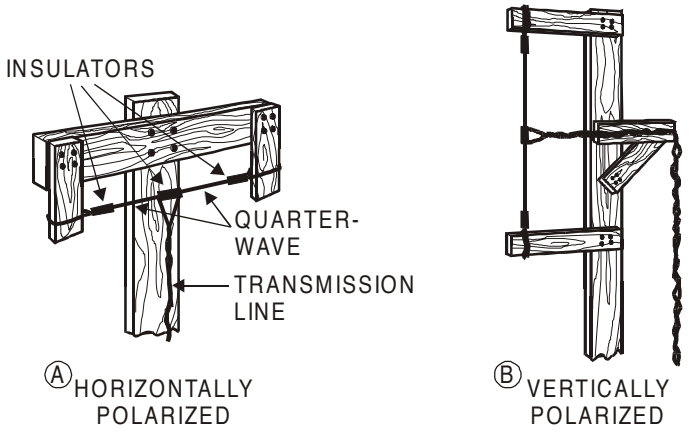

Figure O-7. Center-Fed Half-Wave Antenna.

A similar arrangement for a short, center-fed half-wave antenna is shown in figure O-8. The ends of this antenna are connected to a piece of dry wood, such as a bamboo pole, and the bend in the pole holds the antenna wire straight. Another pole, or bundle of poles, serves as the mast.

Figure O-9 shows an improvised vertical half-wave antenna. This technique is used primarily with FM radios. It is effective in heavily wooded

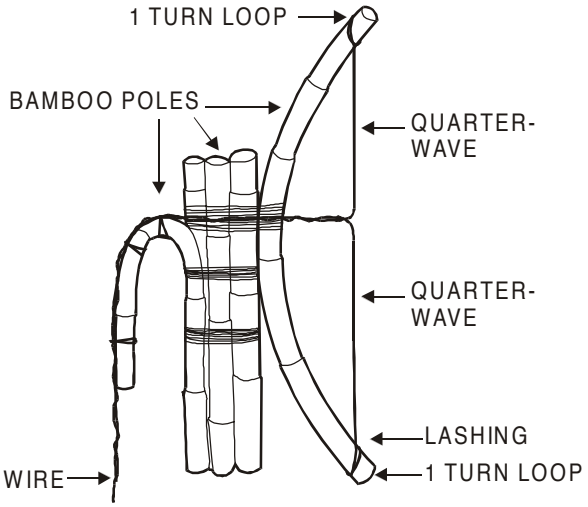

Figure O-8. Bent Bamboo Antenna.

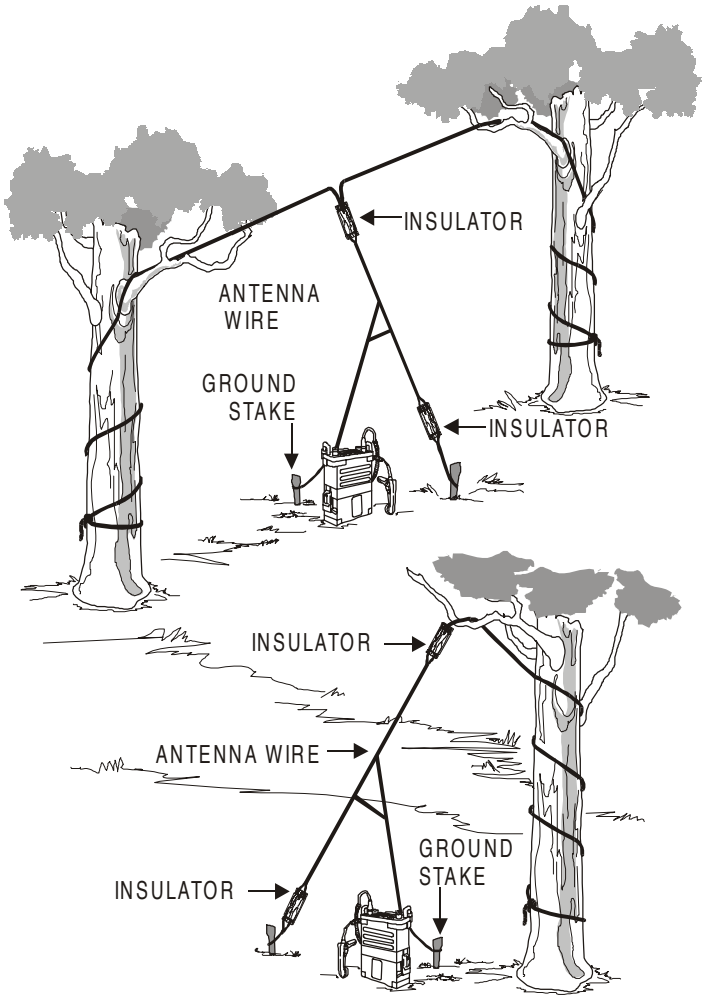

Figure O-9. Improvised Vertical Half-Wave Antennas.

areas to increase the range of portable radios. The top guy wire can be connected to a limb or passed over the limb and connected to the tree trunk or a stake.

HIGH FREQUENCY, FIELD EXPEDIENT DIRECTIONAL ANTENNAS

The vertical half-rhombic antenna (fig. O-10 on page O-12) and the long-wire antenna (fig. O-11 on page O-12) are two field expedient,

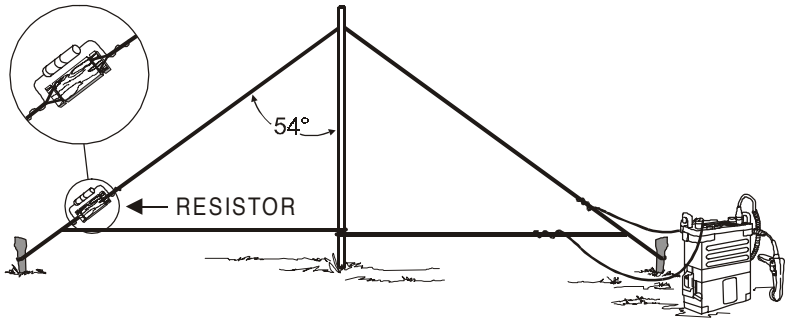

Figure O-10. Vertical Half-Rhombic Antenna.

directional antennas. These antennas consist of a single wire, preferably two or more wavelengths long, supported on poles at a height of 3 to 7 meters (10 to 20 feet) above the ground. The antennas will, however, operate satisfactorily as low as 1 meter (approximately 3 feet) above the ground. The far end of the wire is connected to ground through a noninductive resistor of 500 to 600 ohms. Use a resistor rated at least one-half the wattage output of the transmitter to ensure the resistor is not burned out by the output power of the transmitter. A reasonably good ground, such as a number of ground rods or a counterpoise, should be used at both ends of the antenna. The radiation pattern is directional. The antennas are used primarily for either transmitting or receiving high frequency signals.

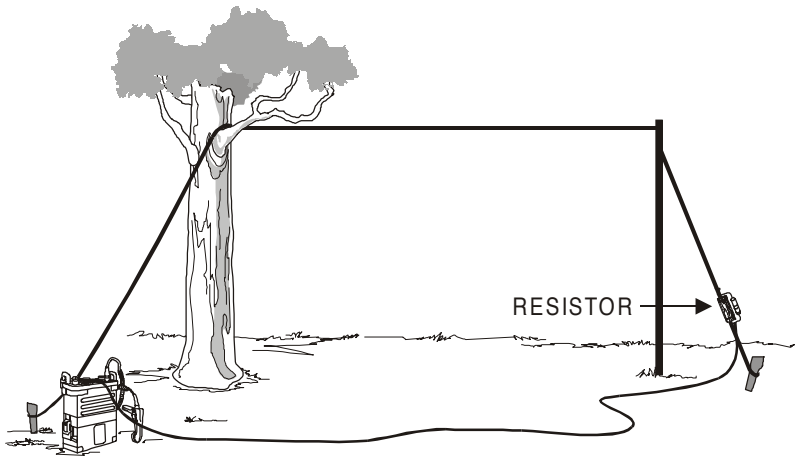

Figure O-11. Long-Wire Antenna.

The Vee antenna is another field expedient, directional antenna. It consists of two wires forming a Vee with the open area of the Vee pointing toward the desired direction of transmission or reception (see fig. O-12). To make construction easier, the legs may slope downward from the apex of the Vee (this is called a sloping Vee antenna [see fig. O-13 on page O-14]).

The angle between the legs varies with the length of the legs in order to achieve maximum performance.

When the antenna is used with more than one frequency or wavelength, use an apex angle that is midway between the extreme angles determined by the chart.

To make the antenna radiate in only one direction, add noninductive terminating resistors from the end of each leg (not at the apex) to ground.

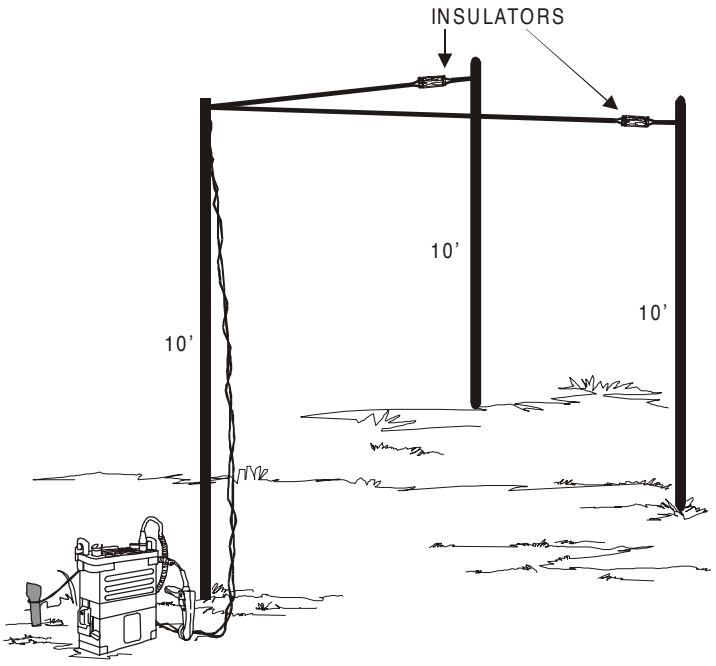

Figure O-12. Vee Antenna.

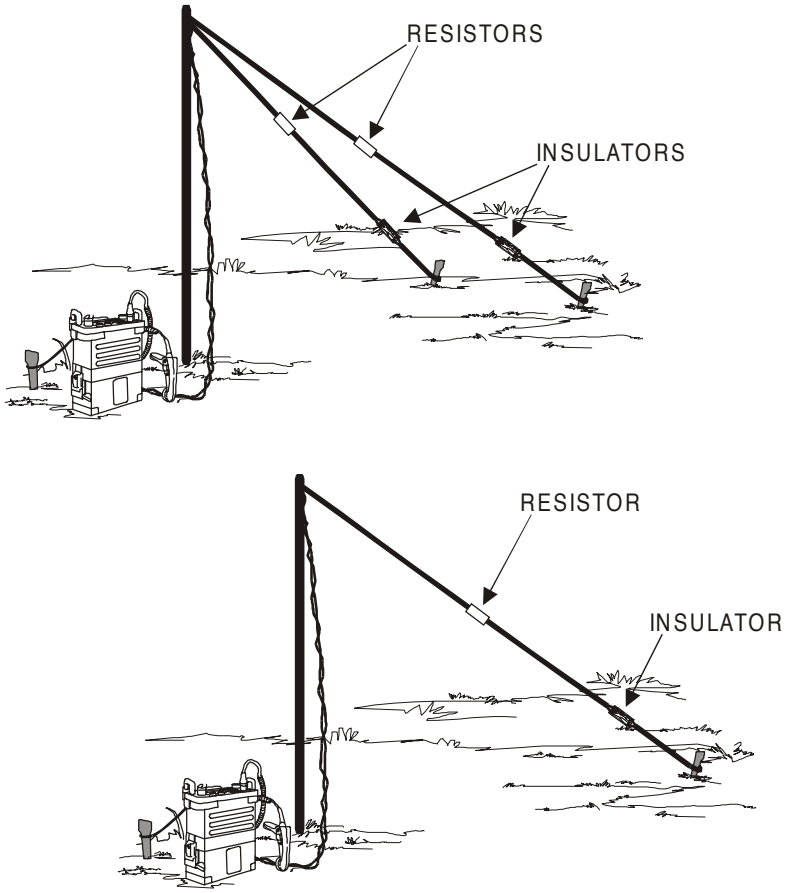

Figure O-13. Sloping Vee Antennas.

The resistors should be approximately 500 ohms and have a power rating at least one-half that of the output power of the transmitter being used. Without the resistors, the antenna radiates bidirectionally, both front and back.

The antenna must be fed by a balanced transmission line.

Use table O-1 to determine the angle and the length of the legs.

Table O-1. Leg Length for Vee Antennas.

Antenna Length (Wavelength)	Optimum Apex Angle (Degrees)
1	90
2	70
3	58
4	50
6	40
8	35
10	33

Appendix P

Radio Operator's Checklist

Before you operate any radio set, get the appropriate equipment technical manual (TM) and carefully study the operating instructions. Refer to the panel diagrams, connections diagrams, and the paragraphs covering the description of components during the preliminary starting procedure. Make sure that the proper cables are connected to the proper panel connectors, and that the controls are correctly set. Even the most experienced operators should check their preliminary procedures against the TM references from time to time to insure accuracy and avoid damaging the equipment. Use the operational checklist and the equipment performance checklist to determine what to do to remedy any problems encountered during starting procedures and operation.

STEPS IN OPERATING RADIO SETS

Radio sets issued to a unit vary in type according to the communications requirements of the unit. For example, some sets may be completely contained in one assembly, while others may consist of separate components that must be properly connected to assemble a complete radio set. The following steps are generally required in operating a radio set.

Check the Set for Completeness

Make sure that all the necessary components and accessories are on hand and ready for use. Refer to the equipment basic issue items list in the TM. Never operate the transmitter without the antenna attached.

Inspect the Condition of the Knobs, Dials, Switches, and Controls

Look for knobs, dials, switches, and controls that are loose on their shafts, bind when being operated, won't operate, or are damaged in any other way. Make corrections where possible or report the faulty

condition to the CIS officer or CIS chief. Make sure that all knobs and exterior parts are on the set. Immediately report any that are missing.

Check the Condition of Plugs, Receptacles, and Connectors

Do not attempt to connect the set for operation until you are sure that the plugs and connectors are clean and in good condition, and the receptacles to which they must be connected are also clean and in good condition.

Check the Connections Diagrams

The connections diagrams in the equipment TM show the type and number of cables required to interconnect the components of the radio set for each type of operation. The radio set may be damaged if cables are connected to the wrong receptacles.

If the connectors don't match, it is possible to physically damage the pins or sleeves of the connector.

If a cable is connected to a receptacle into which it fits but does not belong, it may cause serious electrical damage to the equipment and, in some cases, injury to the operator.

Make Sure of Dial, Switch, and Control Settings

Some radio sets can be seriously damaged if the switches, dials, and controls are not set to the required initial settings before applying power or making the initial timing adjustments. Before applying power, check the equipment TM to be sure you performed all preliminary starting procedures. Be sure radios installed in vehicles are turned off before starting the vehicle's engine to avoid damage to radio equipment.

Follow the Starting Procedure

The equipment TM covers, in detail, the proper procedure for starting the radio set. If there is a specific sequence for starting the set, it is described in the manual. Perform the operations in the proper sequence.

Apply Power

After the proper connections are made, and all switches are properly set, power may be applied to the set.

Allow the Set to Warm Up

Radio sets usually require a warm-up period when first applying power in order to stabilize the equipment. In some cases, it is possible to damage a set by attempting to operate a set without allowing a warm-up period. Most sets are protected against such damage, but it is foolish to risk damage to a radio set by trying to put it on the air before it is ready.

Tune to the Desired Frequency (Channel)

Tune the transmitter to the frequency of the desired channel according to the procedures in the equipment TM. Use the methods that are given in the TM to check for correct tuning.

Check the Set for Normal Operation

While the set is in operation, check the indicators frequently to be sure that the set is operating correctly. If anything unusual occurs during operation, investigate it immediately. When necessary, turn off the power to the set and refer to the operational checklist and the equipment performance checklist in the equipment manual. If the corrections given in the operational checklist and the equipment performance checklist will not correct the trouble, report the condition to the unit electronics maintenance shop. Make sure that the condition of the set and the action taken are properly recorded on the maintenance records.

Use the Proper Procedure to Turn Off the Set

After operation (or if the set is being turned off because of improper operation) make sure that the controls, switches, and dials are properly set (this may not be required on some radios). Proceed to shut down the components of the set in the sequence specified in the equipment manual. Simple radios may require nothing more than turning the power

switch to its OFF position, but more complex sets may require elaborate shutdown procedures.

Operating Hints

Use a handset or headset, rather than a loudspeaker, if the incoming signal is weak. Make sure that the microphone or handset is in good condition. Speak directly into the microphone; speak slowly and distinctly.

Make sure that the vehicle's battery voltage (if radio set is vehicular-mounted) is within the correct range. Keep the engine running to charge the battery. Move the set or the vehicle, if necessary, to improve reception.

Lack of communications or poor communications may be caused by—

- Too great a distance between radio sets.
- Poor choice of location (siting) at one or both ends of the circuit.
- Terrain—hills or mountains.
- Noise and interference.
- Not enough transmitter power.
- Defective equipment.
- Improper adjustment of equipment.
- Ineffective antenna.
- Improper frequency assignment.

Poorly maintained equipment and improper operation can be just as effective in preventing communications as excessive distance or mountainous terrain. To avoid problems, observe the following precautions at all times:

- Study the TMs for the equipment you are using. They provide complete operating instructions and maintenance procedures.
- Keep your radio set clean and dry.
- Handle your radio set carefully.

Appendix Q

Glossary

Section I. Acronyms

AC ..... alternating current
AF ..... audio frequency
AM ..... amplitude modulation
ASAP ..... as soon as possible
ASIP ..... advanced systems improvement program

bps ..... bits per second

C4I ..... command, control, communications, computers, and intelligence
CDT ..... Central Daylight Time
CEOI. ..... communications-electronics operating instruction
CEP ..... circular error of probability
CIS ..... communications and information systems
cm ..... centimeter
COMINT ..... communications intelligence
COMSEC ..... communications security
CONUS ..... continental United States
COTS ..... commercial off-the-shelf equipment
CST ..... Central Standard Time

DACT ..... data automated communications terminal
DAMA ..... demand assigned multiple access
db ..... decibel
DC ..... direct current
DCT ..... digital communications terminal
dm ..... decimeter
dkm ..... dekameter
DMS ..... digital message system

DTE ..... data terminal equipment
DTG ..... date-time group

EA ..... electronic attack
EDT ..... Eastern Daylight Time
EEFI ..... essential elements of friendly information
EMCON ..... emission control
EMP ..... electromagnetic pulse
EP ..... electronic protection
EPLRS ..... enhanced position location reporting system
ES ..... electronic warfare support
EST ..... Eastern Standard Time
EW ..... electronic warfare

FAC ..... forward air controller
FLOT ..... forward line of own troops
FM ..... frequency modulation
FMF ..... Fleet Marine Force
FMFM ..... Fleet Marine Force manual

GHz ..... gigahertz
GPS ..... global positioning system

HF ..... high frequency
Hz ..... hertz
hm ..... hectometer

ID ..... identification
IED ..... imitative electromagnetic deception
IR ..... infrared

JC2WC ..... Joint Command and Control Warfare Center
JSC ..... Joint Spectrum Center

KHz ..... kilohertz
km ..... kilometer
kbps ..... kilobytes per second
kW ..... kilowatt

LOS ..... line of sight
LSB ..... lower side band
LUF ..... lowest usable frequency

m ..... meter
MAGTF ..... Marine air-ground task force
MCRP ..... Marine Corps reference publication
MCWP ..... Marine Corps warfighting publication
MDT ..... Mountain Daylight Time
MEU(SOC) ..... Marine expeditionary unit (special operations capable)
MFP ..... moisture fungusproofing paint
MHz ..... megahertz
mi ..... miles
MIJI ..... meaconing, intrusion, jamming, interference
mm ..... millimeter
MPF ..... maritime prepositioning force
MST ..... Mountain Standard Time
MUF ..... maximum usable frequency
MUX ..... multiplex

NBC ..... nuclear, biological, and chemical
NCS ..... net control station
NVIS ..... near vertical incidence skywave

ohm ..... a unit of electrical resistance (named for Georg Ohm)
OTH ..... over the horizon

prosign ..... precedure sign
proword ..... procedure word
PDT ..... Pacific Daylight Time
PLRS ..... position location reporting system
PST ..... Pacific Standard Time

RCU ..... remote control unit
RDF ..... radio direction finder
RF ..... radio frequency
RFI ..... radio frequency interference

SAA ..... satellite access authorization
SATCOM ..... satellite communications

SBB ..... switched backbone
SCR ..... single channel radio
SCSI ..... small computer systems interfaces
SHF ..... super-high frequency
SID ..... sudden ionospheric disturbance
SINCGARS ..... single-channel ground and airborne radio system
SIP ..... systems improvement program
SOP ..... standing operating procedure
SPEED ..... system planning, engineering, and evaluation device
SSB ..... single side band
SWR ..... standing-wave ratio

TACSAT ..... tactical satellite
TAMCN ..... table of authorized materiel control number
TCIM ..... tactical communications interface module
TDN ..... tactical data network
TEMPEST ..... an unclassified name referring to the means used to ensure computer security
TM ..... technical manual
TOD ..... time of day
TRANSEC ..... transmission security
TWA ..... tilt whip adaptor

UHF ..... ultrahigh frequency
USB ..... upper side band
UTC ..... Coordinated Universal Time
UTM ..... universal transverse mercator
UV ..... ultraviolet

VHF ..... very high frequency

WBA ..... whip-base adapter
WLC ..... whip loading coil
WWA ..... whip to wire adapter

yd ..... yard

Section II. Definitions

A

amplitude modulation (AM). Modulation in which the amplitude of the carrier wave is varied above and below its normal value in accordance with the intelligence of the signal being transmitted.

analog. A continuously variable signal which conveys information by the change of the value or magnitude of the signal. The signal can change in either amplitude, phase, frequency, or duration.

antenna gain. The effectiveness of a directional antenna as compared to a standard nondirection antenna. It is usually expressed as the ratio in decibels of standard antenna input power to directional antenna input power that will produce the same field strength in the desired direction. For a receiving antenna, the ratio of signal power values produced at the receiver input terminals is used. The more directional an antenna is, the higher is its gain.

authentication. A security measure designed to protect a communications system against acceptance of a fraudulent transmissions or simulation by establishing the validity of a transmission, message, or originator.

B

baseband. In a carrier (or subcarrier) wire or radio transmission system, the band of frequencies occupied by the signal before it modulates the carrier (or subcarrier) frequency to form the transmitted or radio signal.

black. The black designation is applied to all wire lines and equipment within a terminal or switching facility which handle encrypted traffic.

brevity code. A code which provides no security but which has as its sole purpose the shortening of messages rather than the concealment of their content.

bulk encryption. An application of on-line cryptographic operations where the encryption and decryption process is performed at designated points of technical interface within a communications system; input-output signals from various subscriber terminals thereby being crypto graphically processed at these points. The operation is performed in bulk; i.e., two or more channels processed simultaneously by one crypto security device.

C

call sign. Any combination of characters or pronounceable words which identifies a communication facility, a command, an authority, an activity, or a unit; used primarily for establishing and maintaining communications.

carrier. (1) The radio wave produced by a transmitter when there is no modulating signal, or any other wave, recurring series of pulses, or direct current capable of being modulated. Also called carrier wave. (2) A wave generated locally at a receiver that, when combined with the sidebands of a suppressed carrier transmission and a suitable detector, produces the modulating wave.

communications security (COMSEC). The protection resulting from all measures designed to deny unauthorized persons information of value which might be derived from the possession and study of telecommunications, or to mislead unauthorized persons in their interpretation of the results of such possession and study. Communications security includes cryptosecurity, transmission security, emission security, and physical security of communications security materials and information.

critical frequency. The highest frequency at which a given wave at any given time will, if transmitted vertically, be refracted back to earth by a layer of the ionosphere.

cryptography. The art or science which pertains to the various means and methods for rendering plain text unintelligible, and reconverting unintelligible texts into intelligible language; application of that science by means other than cryptanalysis.

D

data. Representation of facts, concepts, or instructions in a formalized manner suitable for communication, interpretation, or processing by humans or by automatic means. Any representations such as characters or analog quantities to which meaning is or might be assigned.

date-time group (DTG). The date and time, expressed in digits and zone suffix, the message was prepared for transmission. (Expressed as six digits followed by the zone suffix; first pair of digits denotes the date, second pair the hours, third pair the minutes.)

decibel (dB). A unit used to express the magnitude of a change in signal or sound level. A change of three decibels is the change in power level of a pure sine wave that is just barely detectable by the human ear. The difference in decibels between two signals is 10 times the common logarithm of their ratio of powers or 20 times the common logarithm of their ratio of voltages or currents. One decibel is one-tenth of a bel.

digital. A signal having discrete states, usually two, such as the presence or absence of a voltage. The signal is given meaning by assigning numerical values or other information to the various possible combinations of the discrete states of the signal.

directed net. A net in which no station other than the net control station can communicate with any other station, except for the transmission of urgent messages, without first obtaining the permission of the net control station.

E

electromagnetic radiation. Radiation made up of oscillating electric and magnetic fields and propagated with the speed of light.

electronic warfare (EW). Any military action involving the use of electromagnetic and directed energy to control the electromagnetic spectrum or to attack the enemy. The three major subdivisions within electronic

warfare are: electronic attack, electronic protection, and electronic support measures.

F

free net. A net in which any station may communicate with any other station in the same net without first obtaining permission from the net control station to do so.

frequency. The number of complete cycles per unit of time for a periodic quantity such as alternating current, sound waves, or vibrating objects. Frequency is expressed in hertz, kilohertz, megahertz, and gigahertz.

frequency band. A continuous range of frequencies extending between two limiting frequencies.

Frequency hopping. A method of jumping from frequency to frequency in synchronization with one another in a random order at a rate of up to 100 times per second. Frequency hopping is the preferred method of communication with SINCGARS radios.

frequency modulation (FM). Frequency modulation is the process of varying the frequency (rather than the amplitude) of the carrier signal in accordance with the variations of the modulating signals. The amplitude or power of the FM carrier does not vary during modulation. A frequency modulation system is practically immune to atmospheric and man-made interference.

frequency spectrum designation. VLF (very low frequency): below 30 kHz (0.03 MHz). LF (low frequency): 30-300 kHz (0.03-0.3 MHz). MF (medium frequency): 300-3000 kHz (0.3-3 MHz). HF (high frequency): 3-30 MHz. VHF (very high frequency): 30-300 MHz. UHF (ultra high frequency): 300-3000 MHz. SHF (super high frequency): 3000-30,000 MHz (3-30 GHz). EHF (extremely high frequency): 30-300 GHz.

G

ground wave. A radio wave that is propagated over the earth and is ordinarily affected by the presence of the ground and the troposphere. The ground wave includes all of the components of a radio wave over the earth except ionospheric and tropospheric waves. The ground wave is refracted because of variations in the dielectric constant of the troposphere, including the condition known as a surface duct.

guard. To maintain a continuous receiver watch with transmitter ready for immediate use. A complete log is to be kept.

H

half-duplex—Refers to a mode of transmission in which communication between two terminals occurs in either direction, but in only one direction at a time. This is the typical mode of operation for tactical single-channel radios.

hertz (Hz). A unit of frequency equal to one cycle per second.

I

imitative communication deception (ICD). The introduction of radiation into enemy systems which imitate the enemy's emissions.

in the clear. In plain text. When cryptographic devices are not used to protect a transmitted signal.

ionosphere. A region in the earth's outer atmosphere where ions and electrons are present in quantities sufficient to affect the propagation of HF radio waves. It begins about 30 miles above the earth and extends above 250 miles, with the height depending on the season of year and the time of day. The chief layers of the ionosphere and their approximate heights are:
D layer—30 to 60 miles
E layer—60 to 90 miles
F layer—90 to 250 miles

J

jamming (electromagnetic). The deliberate radiation, reradiation, or reflection of electromagnetic energy for the purpose of preventing or reducing an enemy's effective use of the electromagnetic spectrum, and with the intent of degrading or neutralizing the enemy's combat capability.

L

line of sight (LOS). The straight unobstructed path between two points.

link. In communications, a general term used to indicate the existence of communications facilities between two points.

log. A chronological record of station events.

N

needline. A requirement to establish communications between two units or agencies.

net (communications). An organization of stations capable of direct communications on a common channel or frequency.

net call sign. A call sign which represents all stations within a net.

net control station. A communications station designated to control traffic and enforce circuit discipline within a given net. Also called NCS.

O

obstacle gain. The increase in signal strength obtained over a long radio communications path where a mountain obstacle or range of hills is located about halfway between transmitting and receiving antennas. This obstacle gain offsets some of the path losses normally expected.

operating signals. Three letter groups used as necessary in connections with operations or communications to convey orders, instructions, requests, reports, and information to facilitate communications.

P

precedence. In communications, a designation assigned to a message by the originator to indicate to communications personnel the relative order of handling and to the addressee the order in which the message is to be noted.

procedure sign (prosign). One or more letters or characters, or combination thereof, used to facilitate communications by conveying in a condensed standard form certain frequently used orders, instructions, requests, and information related to communications.

procedure word (proword). A word or phrase limited to radio telephone procedure used to facilitate communication by conveying information in a condensed standard form.

Propagation. A phenomenon by which any wave moves from one point to another.

pulse code modulation (PCM). The form of modulation in which the modulating signal is sampled, and the sample quantitized and coded so that each element or information consists of different kinds and/or numbers of pulses and spaces.

pulse position modulation (PPM). A form of pulse modulation in which intelligence is conveyed by varying the time interval by which successive pulses are displayed from their normal times of occurrence.

push to talk operation. Voice communications on a circuit in one direction at a time in which operation of a switch is required prior to and during transmission.

R

radio frequency (RF). A frequency in which coherent electromagnetic radiation of energy is useful for communications purposes. The useful range is from approximately 10 kilohertz to 100,000 megahertz.

radio silence. A condition in which all or certain radio equipment capable of radiation is kept inoperative. (In combined or U.S. joint or intra Service communications the frequency bands and/or types of equipment affected will be specified.)

red. Designation applied to transmission lines, equipment, systems, and/or areas passing unencrypted signals.

S

satellite communications. Use of communication satellites, passive reflecting belts of dipoles or needles, or reflecting orbiting balloons to extend the range of radio communications by returning signals to earth from the orbiting objective, with or without amplification.

simplex. Refers to a mode of operation in which communication between two terminals can take place in only one direction.

skip distance. The minimum separation at which radio waves over a specified frequency can be transmitted at a specific time between two points on the earth by reflection from the regular ionized layers of the ionosphere.

skip zone. A region, in relation to a given transmitter, in which no signal would be predicted, either due to direct repetition or due to reflected waves.

sky wave. A radio wave that reaches the receiving location after refraction from the ionosphere.

T

tactical radio net. A functional radio net used by a commander for immediate and direct control of the fire and maneuver or movement of his subordinate units.

traffic. All transmitted and received messages.

transceiver. A radio transmitter and receiver combined in one unit and having switching arrangements such as to permit use of one or more circuit components for both transmitting and receiving.

transducer. A device that transfers or changes one type of energy into another form. An example is a loudspeaker, which changes electrical energy into acoustic (mechanical) energy.

Abstract — This paper addresses an innovative and ultra-compact rectenna designed for energy harvesting or wireless power transfer applications. The presented rectenna uses a printed cross dipoles antenna array and a rectifier implemented with only one silicon Schottky diode. Experimental results show that 1.15 mW of DC power can be obtained for an optimal load impedance of 500 Ω using a compact rectenna (2.5 cm^2 or 0.6 square wavelength) illuminated by an electric field of 60 V/m at 14.7 GHz.

Index Terms — Rectennas, microwave energy harvesting, wireless power transfer

I. Introduction

Microwave spectrum (beyond 10 GHz) presents an increased interest for wireless power transfer [1] or energy harvesting [2] applications. Rectenna topologies working at such frequencies were designed in the past [2]-[7] by using exclusively GaAs Schottky diodes. One of the main challenges of rectenna design, especially at such high frequencies, is to provide a high-efficiency by using a compact design and low-cost electronic components (e.g., silicon Schottky diodes). This paper addresses an innovative rectenna topology and the associated design methodology. The topology and the associated design rules are presented in Section II. The experimental results reported in Section III demonstrate that this topology allows implementing an ultra-compact and high efficiency microwave rectenna.

II. Rectenna Topology and Design

The proposed topology selected to meet the two main design goals (i.e., conversion efficiency and structure compactness) is shown in Fig. 1. It is composed by: (i) a compact antenna array of two crossed printed dipoles located on the top of the PCB; (ii) a rectifier using only one Schottky diode. The rectifier (except the Schottky diode) is located at the bottom side of the PCB. A ground plane can be positioned below antenna/rectenna to immunize the rectenna performances from the electromagnetic properties of any mechanical support, to increase the gain of the antenna and consequently, to enhance the overall efficiency of the rectenna.

A. Antenna design

Three criteria were taken into account during antenna design and optimization: (i) *compactness*: the total size occupied by the antenna should be as small as possible, (ii) *high gain/high efficiency*: for maximizing the amount of the RF power available at the input of the rectifier and, (iii) *input impedance matching*: antenna input impedance (Z_{inA}) has to match the input impedance of the rectifier (Z_{inR}) for maximizing the power transfer between antenna and rectifier ($Z_{inA}=Z_{inR}^*$, where Z_{inR}^* denotes the complex conjugate of Z_{inR}) at the targeted operating frequency.

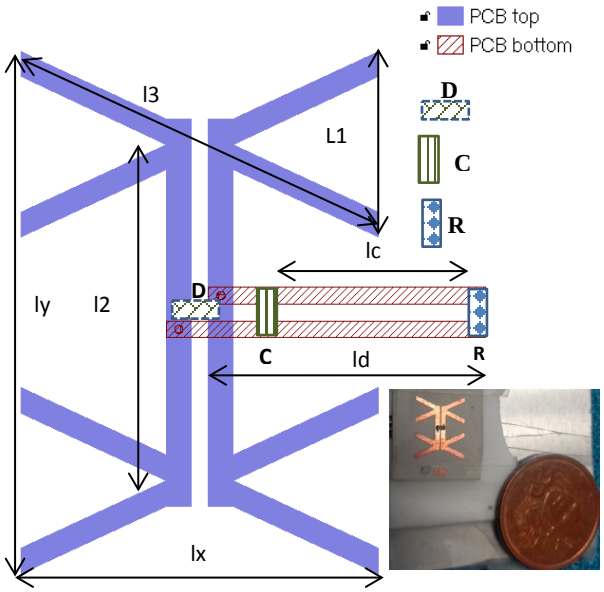

Fig. 1. Top view (not to scale) of the layout of the rectenna, its main geometrical dimensions and a photo (inset, right corner) of the manufactured rectenna

B. Rectifier design

A low-cost silicon Schottky diode (SMS201 from Aeroflex Metelics) in a molded plastic (DFN) package was adopted for this design. This diode can be used for broadband zero bias detectors or power detection up to 10 dBm (frequency below 26.5 GHz). The SMS201 diode has a good thermal behavior and can be mounted using a classical soldering process at high temperature (260°C) while the GaAs diodes require a more sensitive mounting process at a lower temperature (< 150°C). A RF shunt capacitor is connected between the diode and the load resistor as shown in Fig. 1. The simulation model of the rectifier was implemented into AWR software (Fig. 2). The diode was modeled based on the Metelics application note [8]. The rectenna was designed and fabricated on Rogers 6002

substrate (relative permittivity: 2.94, loss tangent: 0.0012 and thickness: 508 µm).

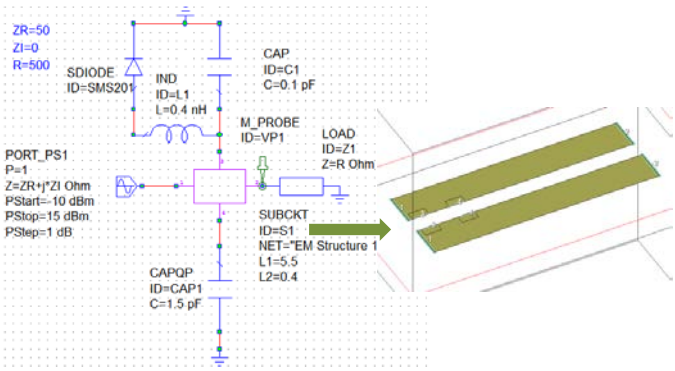

Fig. 2. Simulation model (AWR) of the rectifier.

C. Design methodology and optimization process

Rectenna design, simulation and optimization at such a high frequency involve the use of full-wave electromagnetic simulation tools combined with non-linear (e.g. harmonic balance) electrical circuit models.

First, non-linear simulations were performed by using the AWR model reported on Fig. 2 and an optimal value was determined for the shunt RF capacitor (C=1.5 pF) and for the load resistance (R=500 Ω). The coplanar stripline sections supporting the rectifier were modeled as a sub-circuit at the electromagnetic level due to the lack of appropriate transmission line models in AWR. The via-hole used to connect the diode (mounted on the top side of the PCB) with the bottom of the PCB (the rectifier, except the diode, is located on the bottom side of the PCB) was not simulated in our model. A parametric analysis was performed in order to find the best position for the capacitor mounting. At this stage of the simulation it was found that the distance between the diode and the capacitor (ld-lc) should be as small as possible.

Second, a simulation model of the antenna array (top side of the PCB) was performed using Feko electromagnetic software. The main geometrical parameters of antennas are: the length of the crossed dipole arms (ld), the angle between crossed dipoles (α), the array step (l2), the strip width (w) and, the gap between the strips of the coplanar stripline (g). The length of the crossed dipole arms (ld) and the array step (l2) must be close to the half-wavelength at the operating frequency. In order to increase the gain of the antenna array and to immunize the rectenna performances from the electromagnetic properties of any mechanical support a metallic ground plane was positioned bellow the PCB. At this step of the design the radiation pattern and the current distribution on the strip section of antenna array were checked to verify the proper radiation mechanism. The input of antenna array is loaded by the rectifier impedance.

The rectenna layout is very compact and the antenna performances can be impacted by the presence of the rectifier. Thus an improved simulation model was developed by taking into account the entire layout (top and bottom side of the PCB). The diode was replaced by a voltage port while the capacitance (1.5 pF) and the load impedance (500 Ω) were modeled as port loads. By using this simulation model the impact on antenna performances of the overall rectifier layout (except the non-linear behavior of the diode) was taken into account.

Finally the antenna layout (l3 and l2) as well as the position of the shunt RF capacitor were tuned in order to ensure the matching condition $Z_{inA}=Z_{inR}^{*}$.

III. Results

The layout of the optimized rectenna was accommodated with the manufacturing tolerances available in a University unit equipped for general (low frequency) PCB manufacturing. A metallic plane was positioned at 1.2mm below the rectenna with a 1.2 mm thick Rohacell (dielectric constant in the range of 1.08) intercalated as spacer between rectenna and its reflector. The main dimensions of the manufactured rectenna (see Fig. 1) are: lx=8.4mm, ly=12.4mm, l1=4.4mm, l2=8mm, ld=6.5mm, lc=5.5 mm l3=10 mm, w=0.6 mm and g=0.4 mm. The overall surface of the PCB is 2.5 cm^2 ($0.6\lambda^2$).

A. Experimental setup

An experimental setup (shown in Fig. 3) was used in order to recreate the electromagnetic environment existing on antenna panels of the broadcasting satellites. A microwave signal generated from an Anritsu MG3694B generator was injected at the input of a horn antenna which illuminated the rectenna under test with a linear polarized E-field.

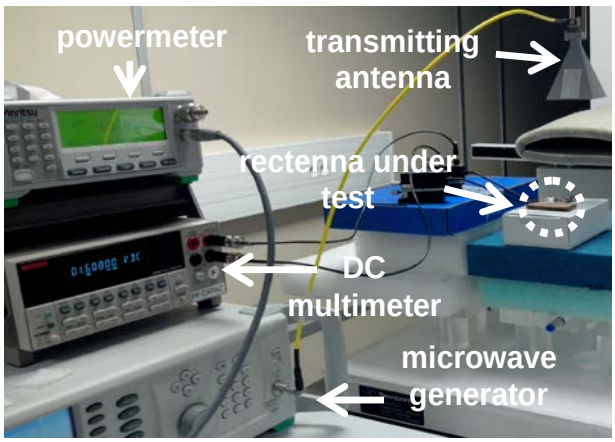

Fig. 3. Experimental setup.

An automatic acquisition routine was implemented in Labview software from National Instruments to speed-up the acquisition process. The harvested DC voltage was measured by using a DC multimeter. The DC power can be computed from the measured DC voltage as long as the load is known. The RF output power delivered by the signal generator was 24 dBm and the measured loss due to the coaxial cable and connectors between antenna and the signal generator was in the range of 2.5 dB in the operating frequency band.

B. Experimental and simulation results

The simulated radiation pattern (gain) at 14.7 GHz is shown in Fig. 4. A standard 3D Cartesian coordinate system with the vertical Oz axis perpendicular to the rectenna/antenna surface is chosen here.

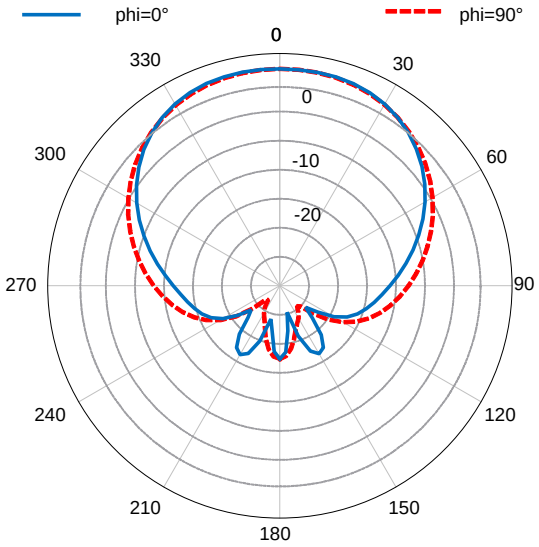

Fig. 4. Simulated (FEKO) gain of the antenna array: (xoz-plane: phi=0° and yoz-plane: phi=90°) at the frequency f=14.7 GHz.

The DC voltage on the input of a variable load (from 0.1 kΩ to 10 kΩ) was measured for the fabricated rectenna. Fig. 5 shows the DC power measured with a load impedance of 500Ω. The rectenna delivers the maximum power of 1.15 mW (load: 500 Ω) at 14.7 GHz. Fig. 6 shows the measured harvested DC power as function of the load impedance.

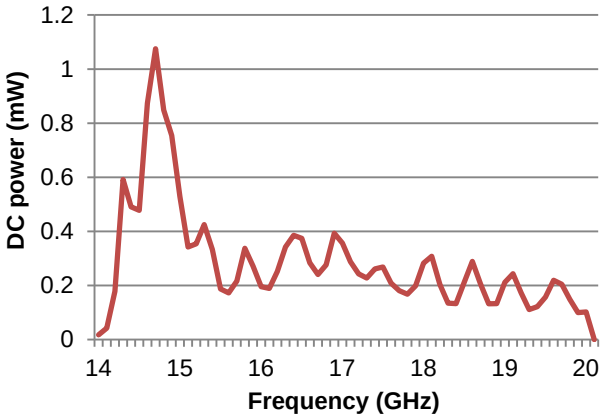

Fig. 5. Measured DC power on a load of 500 Ω as function of frequency.

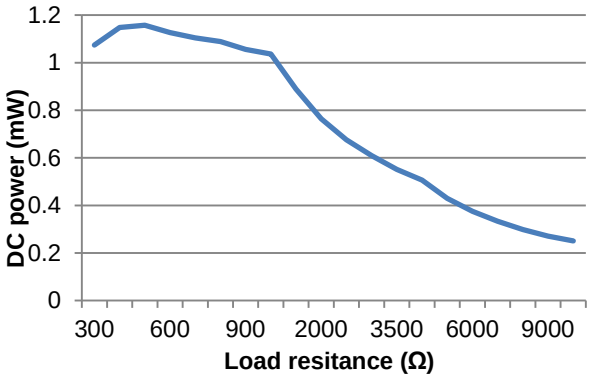

Fig. 6. Measured DC power at 14.7 GHz as function of the load resistance.

The efficiency η (in %) of the rectenna can be computed by using the following definition [9]:

$$\eta_1 = \frac{P_{DC}}{S \cdot A_G} \cdot 100 \qquad (1)$$

$$\eta_2 = \frac{P_{DC}}{S \cdot A_{eff}} \cdot 100 = \frac{4 \cdot \pi \cdot P_{DC}}{S \cdot G_R \cdot \lambda^2} \cdot 100 \qquad (2)$$

where P_{DC} is the harvested DC power, S is the incident electromagnetic power density, A_G (in cm^2) denotes the area of the radiating surface, A_{eff} is the antenna effective area, G_R is the gain of the (rectenna's) antenna and λ is the wavelength of the illuminating electromagnetic wave. The efficiency η_1 can be viewed as a 'worst-case' definition because $A_{eff} \leq A_G$ for any passive antenna. The power density ($\mu W/cm^2$) can be computed as a function of E-field effective value E (V/m) on the antenna surface or as a function of the RF power P_t delivered to the transmitting horn antenna of gain G_t and positioned at the distance *d* from the rectenna, as follows:

$$S = \frac{E^2}{120 \cdot \pi} \cdot 100 = \frac{30 \cdot P_t \cdot G_t}{d^2 \cdot 120 \cdot \pi} \cdot 100 \qquad (2)$$

Here $P_t \approx 21.5$ dBm, $G_t \approx 16.9$ dBi and d=19 cm. Thus E≈60 V/m and S~955 $\mu W/cm^2$. By taken into account the overall area of the rectenna $A_G \approx 2.5$ cm^2 a conversion efficiency around of η_1=48% (η_2=66% by taking into account the simulated gain of G_R=7.4 dBi depicted in Fig. 4) at 14.7 GHz (DC power of 1.15 mW) were obtained. A comparison with the state-of-the-art (operating frequency beyond 10 GHz) is presented in Table I (note that all the diodes -except SMS201- are GaAs diode). Few papers present the measured efficiency of the overall rectenna and, most papers report only the efficiency of the rectifier block of the rectenna.

* NR : Not Reported

IV. CONCLUSION

A compact rectenna ($0.6\lambda^2$) operating in Ku-band was designed and characterized. Despite of the use of a low-cost silicon Schottky diode the manufactured rectenna exhibits an efficiency of 48% at 14.7 GHz. This rectenna exhibits an excellent trade-off between compactness and efficiency.

ACKNOWLEDGMENT

This work was partially supported by CNES French Space Agency within the framework of R&T n° 115052 contracts. The electronic laboratory of University of Toulouse (Paul Sabatier) is acknowledged for PCB manufacturing.

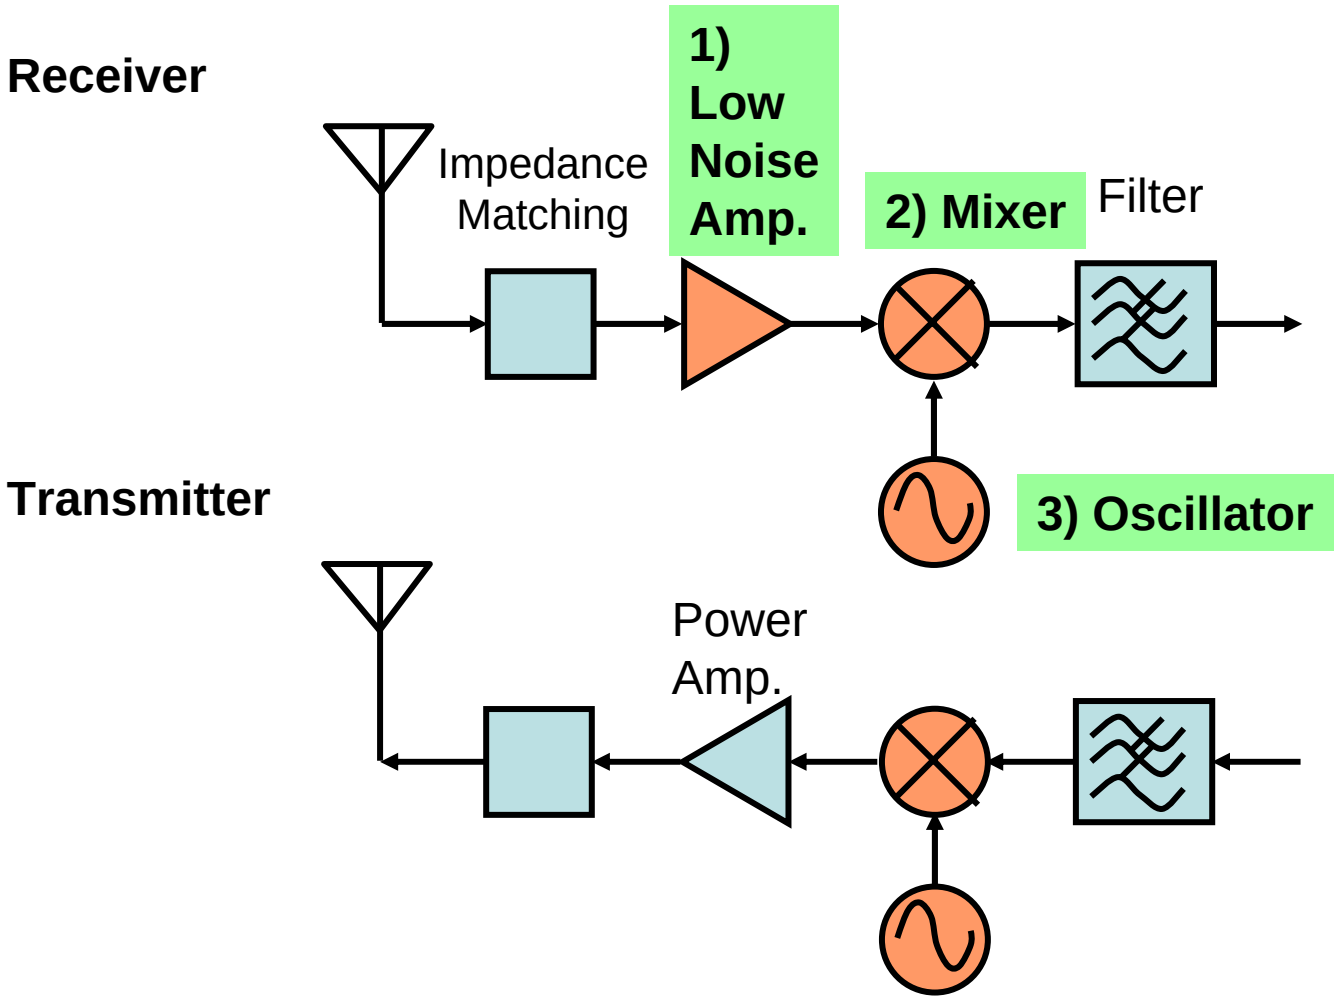
Basic RF circuit block

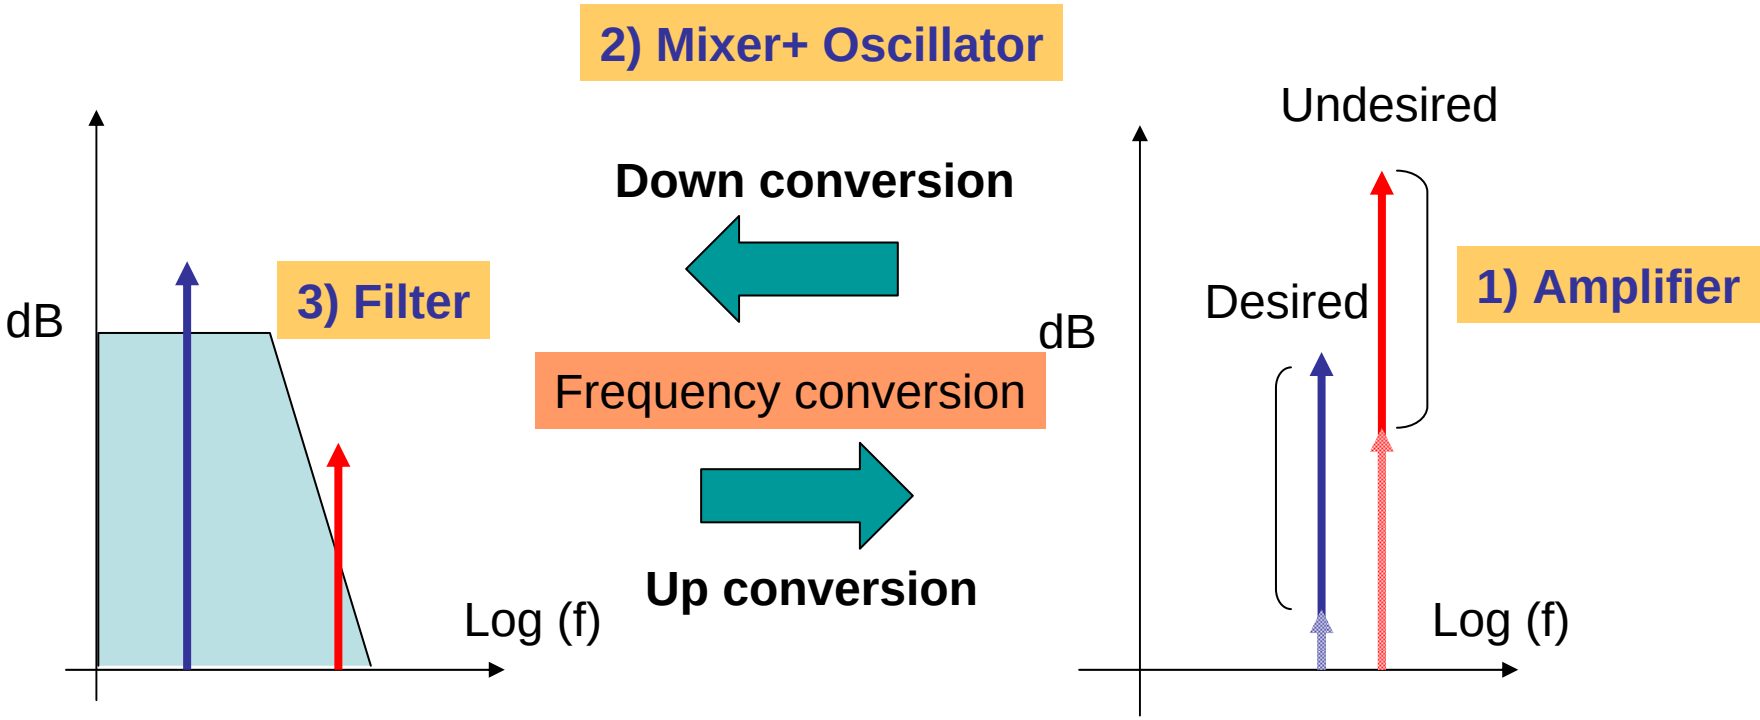
RF systems are composed of limited circuits blocks.

LNA, Mixer, and Oscillator will be discussed in my talk.



Basic functions of RF building blocks

Amplifier, frequency converter (mixer +oscillator), and filer are basic function blocks in RF system.



RF Amplifier

- **Gain:** Amplify small signal or generate large signal.
- **Noise:** Smaller noise and larger SNR.
- **Linearity:** Smaller non-linearity.

Non-linearity generates undesired frequency components.

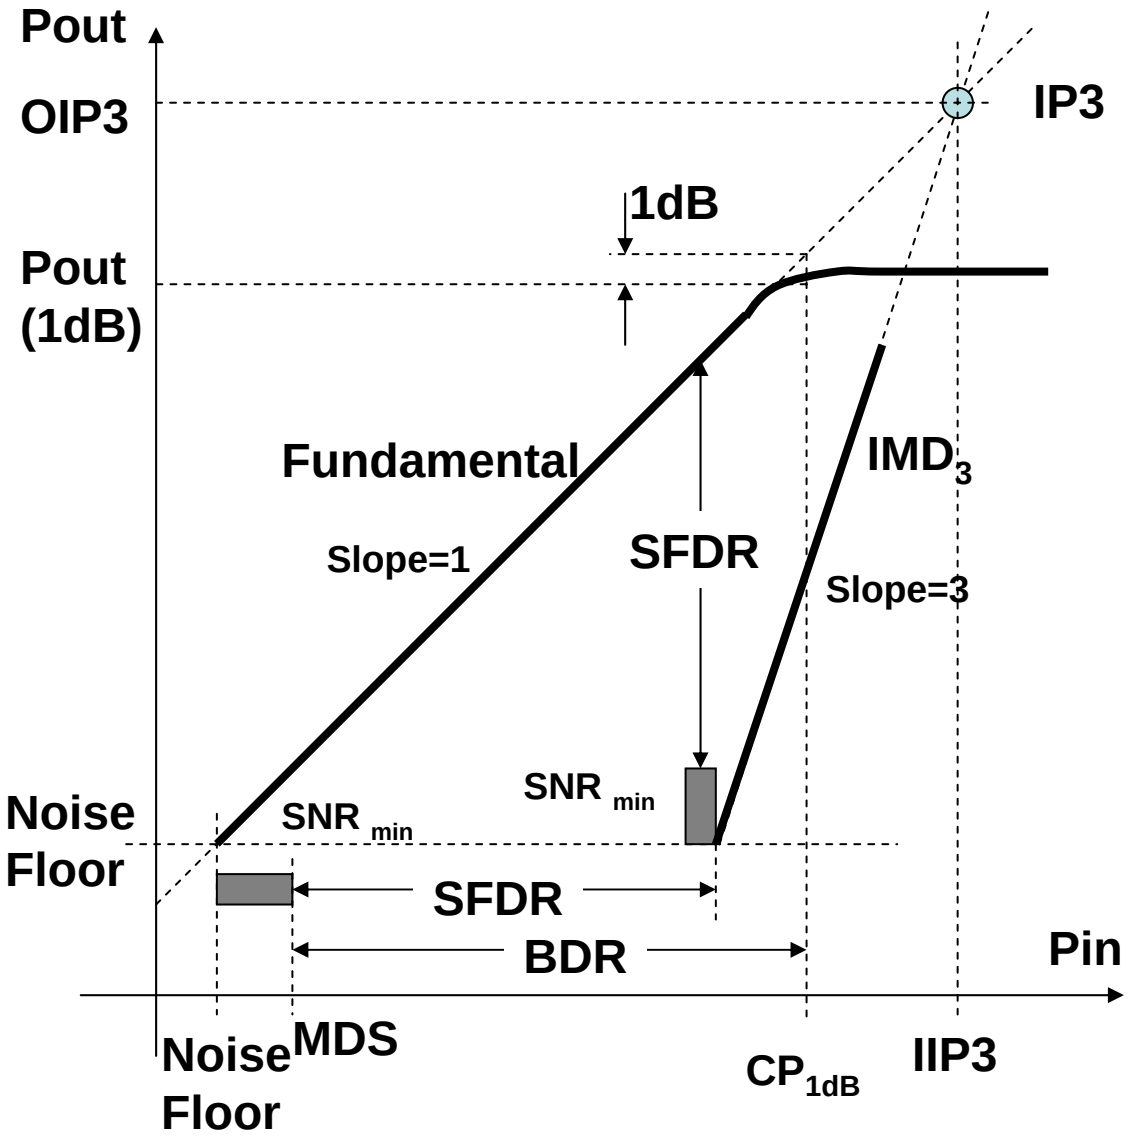
$$v_{out}(t) = \alpha_1 v_{in}(t) + \alpha_2 v_{in}^2(t) + \alpha_3 v_{in}^3(t) + ...$$

$$\left(\cos(\omega_1 t) + \cos(\omega_2 t)\right)^2 = 2 + \cos(2\omega_1 t) + \cos(2\omega_2 t) + \cos((\omega_1 - \omega_2)t) + \cos((\omega_1 + \omega_2)t)$$

$$\left(\cos(\omega_1 t) + \cos(\omega_2 t)\right)^3 = \frac{1}{2}\cos((2\omega_1 - \omega_2)t) + \frac{1}{2}\cos((2\omega_2 - \omega_1)t) + ...$$

Input and output characteristics

Distortion and noise are important factors in RF amplifier, as well as power and gain.



Dynamic range

$$Noise\ Floor = \underbrace{-174dBm}_{\text{kT limitation}} + NF + 10\log\underbrace{BW}_{\text{Bandwidth}}$$

SFDR: Spurious free dynamic range

The input power range over which third order inter-modulation products are below the minimum detectable signal level.

$$SFDR = \frac{2}{3}\left(IIP_3 - Noise\ Floor\right) - SNR_{\min}$$

BDR: Blocking dynamic range

$$BDR = P_{1dB} - Noise\ Floor - SNR_{\min}$$

MDS: Minimum detectable signal level= Noise Floor +SNR_{min}

Non-linearity

CP_{1dB}: The input level at which the small signal gain has dropped by 1dB.

$$CP_{1dB} = \sqrt{0.145\left|\frac{\alpha_1}{\alpha_3}\right|}$$

IMD3: The third order inter modulation term

IP3: The metric third order intercept point. It is the point where the amplitude of third order inter modulation is equal to the that of fundamental.

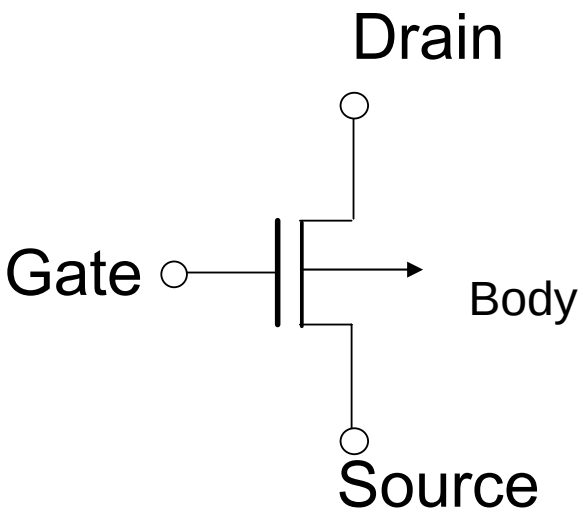
$$A_{IP3} = \sqrt{\frac{4}{3}\left|\frac{\alpha_1}{\alpha_3}\right|}$$

IIP3: Input referred intercept point
OIP3: Output referred intercept point

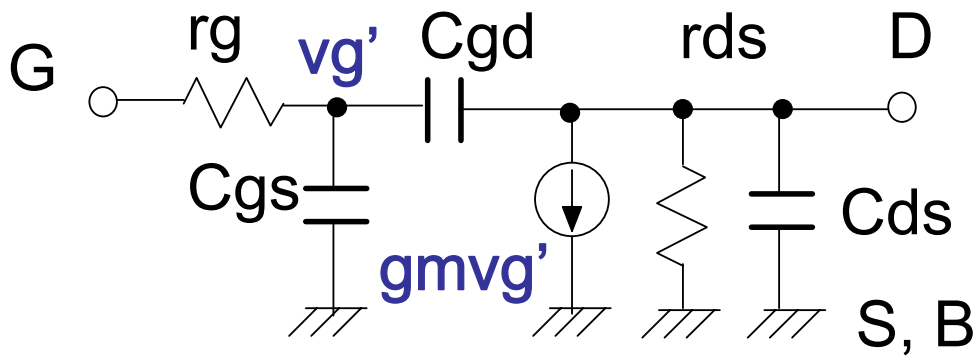
$$P_{out} - IMD_3 = 2 \cdot \left(IIP_3 - P_{in}\right)$$

MOS transistor

Intrinsic gate voltage and gm are the most important factors in RF CMOS.



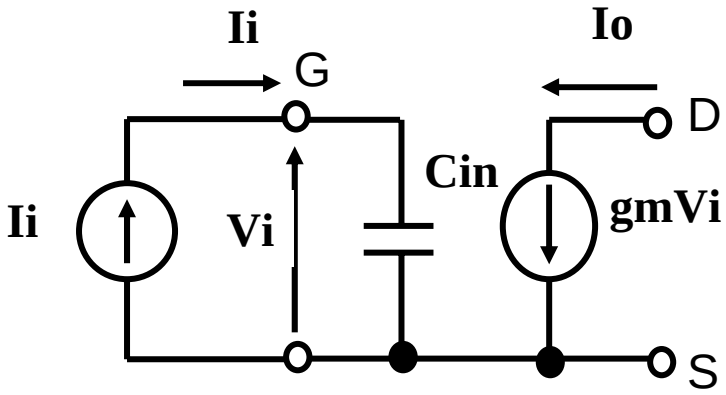
MOS Transistor



Equivalent Circuit

Cutoff frequency: f_T

For higher f_T, increase gm and decrease Cin.



f_T: Frequency at which the current gain is unity.

$$Ii = Iio\sin(\omega t)$$ Input current

$$Vi = \frac{Iio}{\omega C_{in}}\cos(\omega t)$$ Gate voltage

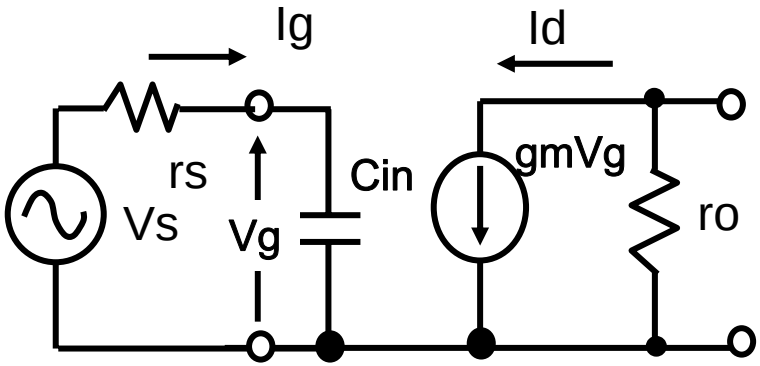
$$Io = gmVi = \frac{gmIio\cos(\omega t)}{\omega C_{in}}$$ Output current

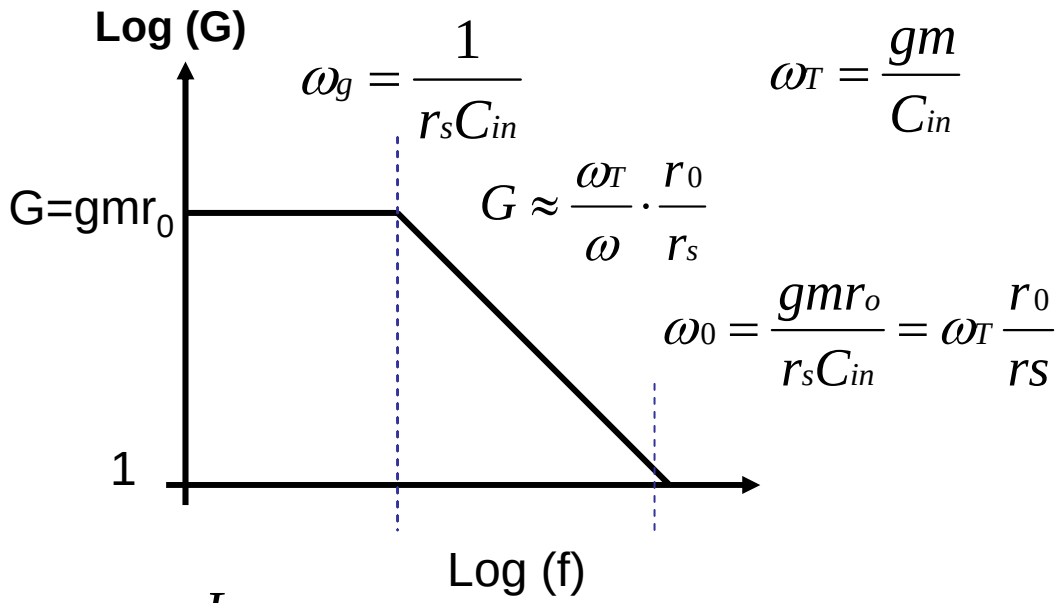
$$\therefore f_T = \frac{gm}{2\pi Cin}$$

Proportional to gm
Inversely proportional to Cin

Amplifier gain

For higher voltage gain, increase gm, f_T, ro (Q), and decrease input and gate resistance





$$\omega_g = \frac{1}{r_s C_{in}} \qquad \omega_T = \frac{gm}{C_{in}}$$

$$G \approx \frac{\omega_T}{\omega} \cdot \frac{r_0}{r_s}$$

$$\omega_0 = \frac{gmr_o}{r_s C_{in}} = \omega_T \frac{r_0}{rs}$$

For the larger gain

Fundamentally larger gmr_0 $G \approx gmr_o \approx \dfrac{I_{ds}}{\left(\dfrac{V_{eff}}{2}\right)} \cdot r_o$ ⇨ Larger I_{ds} or r_o

Larger Q

Higher f_T and lower r_s

V_{eff} is difficult to reduce $\quad \because r_o = Q\omega_0 L = \dfrac{Q}{\omega_0 C}$

→ Distortion and C_{in} increase

Characteristics of gm (Basic)

Gm is proportional to the Ids and inversely proportional to the V_{eff}.

V_{eff} is proportional to square root of I_{ds} and inversely proportional to square root of (W/L) ratio.

Square law region

$$I_{ds} = \frac{\mu C_{OX}}{2n}\left(\frac{W}{L}\right)(V_{gs} - V_T)^2 = \frac{\mu C_{OX}}{2n}\left(\frac{W}{L}\right)V_{eff}{}^2$$

$$gm \equiv \frac{dI_{ds}}{dV_{gs}} = \frac{\mu C_{OX}}{n}\left(\frac{W}{L}\right)V_{eff}$$

$$gm = \sqrt{\frac{2\mu C_{OX}}{n}\left(\frac{W}{L}\right)I_{ds}}$$

$$gm = \frac{Ids}{\left(\frac{V_{eff}}{2}\right)}, \quad \frac{gm}{Ids} = \frac{1}{\left(\frac{V_{eff}}{2}\right)}$$

$$V_{eff} = \sqrt{\frac{2n}{\mu}\cdot\frac{1}{C_{ox}}\cdot\frac{L}{W}\cdot I_{ds}}$$

$$V_{eff} \propto \sqrt{L\frac{Ids}{W}} = \sqrt{L \cdot J_{ds}}$$

Scaling W/L ratio

V_{eff} is proportional to square root of drain current density.

Non-ideal effects to square low region

At larger V_{eff} and lower V_{eff}, two non-ideal effects are not negligible .

Low V_{eff} Sub-threshold region

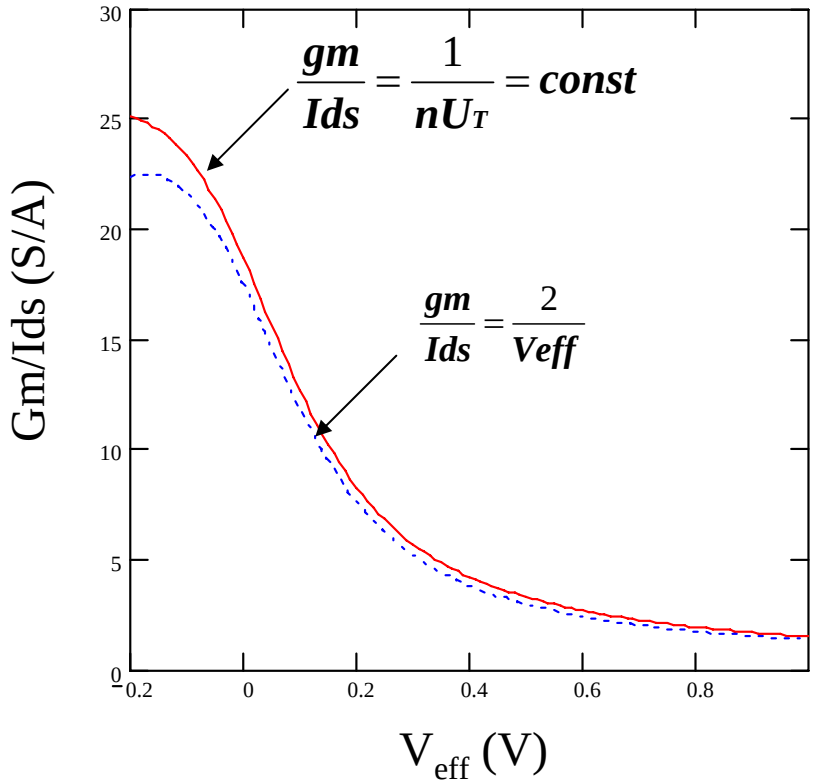
(Weak inversion)

$$I_{ds} = I_{so}\exp\left(\frac{V_{gs}}{nU_T}\right)$$

$$gm = \frac{I_{ds}}{nU_T} \qquad \frac{gm}{I_{dS}} = \frac{1}{nU_T}$$

High V_{eff} Mobility degradation

$$\mu \approx \frac{\mu_0}{1+\theta V_{eff}}, \quad \theta \approx \theta_0 + \frac{\mu_0}{v_c L}$$



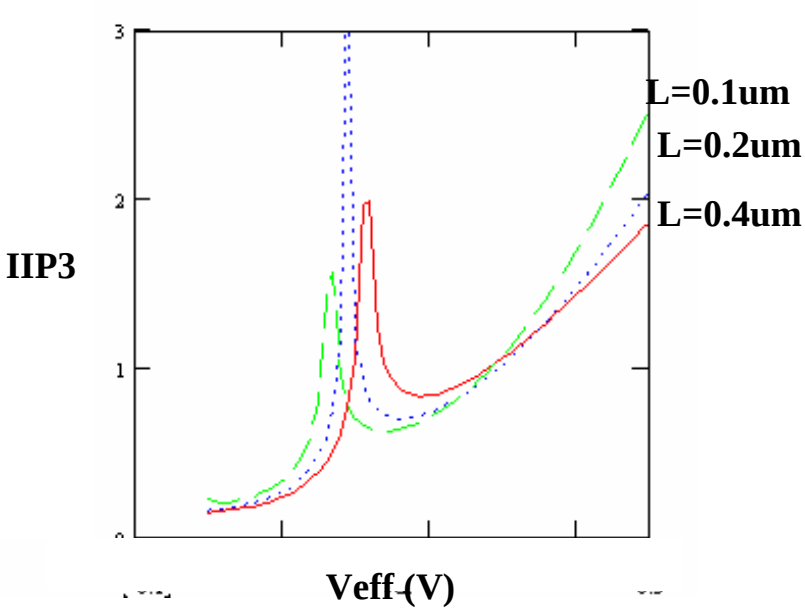
This effect becomes larger at large V_{eff} and short channel length.

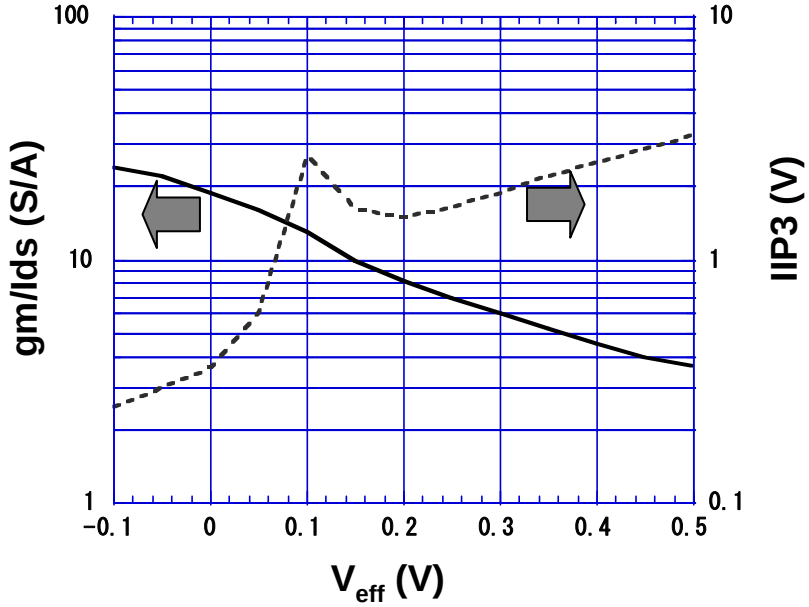
Distortion

Lower V_{eff} gives higher gm, bur results in higher distortion.
To obtain lower distortion (higher IIP3), we must increase V_{eff}.

Higher gm and lower distortion means higher Ids.

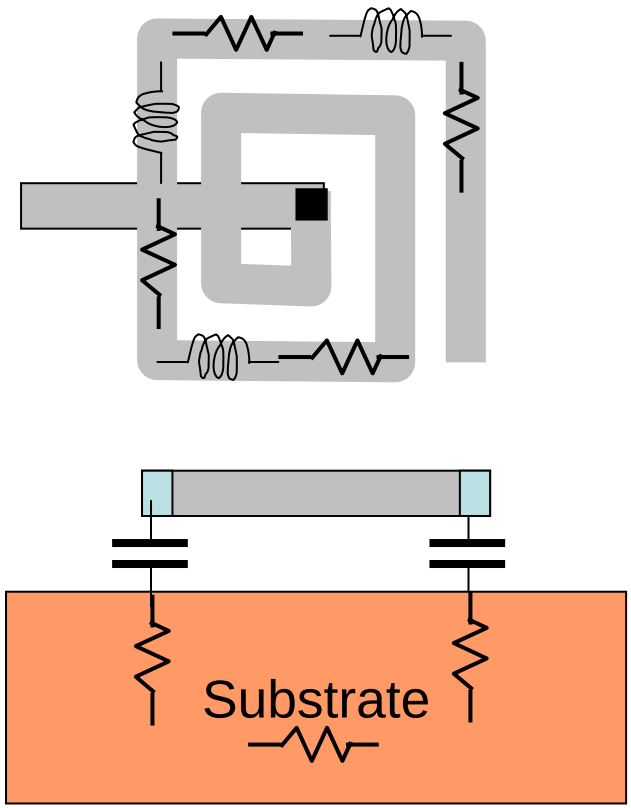
$$Ids = a_1 V_{eff} + a_2 V_{eff}^{\ 2} + a_3 V_{eff}^{\ 3} + \cdots \qquad a_3 \equiv \frac{1}{6}\frac{d^3 I_{ds}}{dV_{eff}^{\ 3}} \qquad I_{IP3} = \sqrt{\frac{4}{3}\left|\frac{a_1}{a_3}\right|}$$

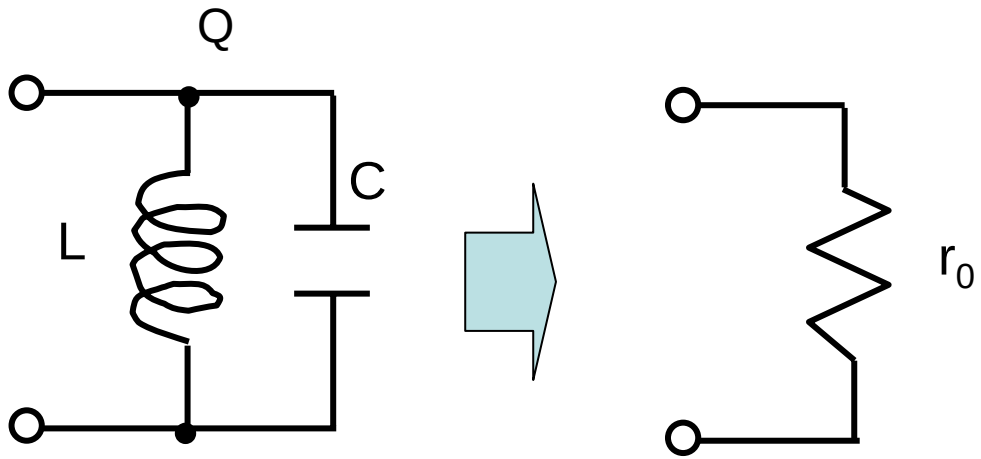




LC resonator

LC resonator can be regarded as resistance at the resonance frequency.





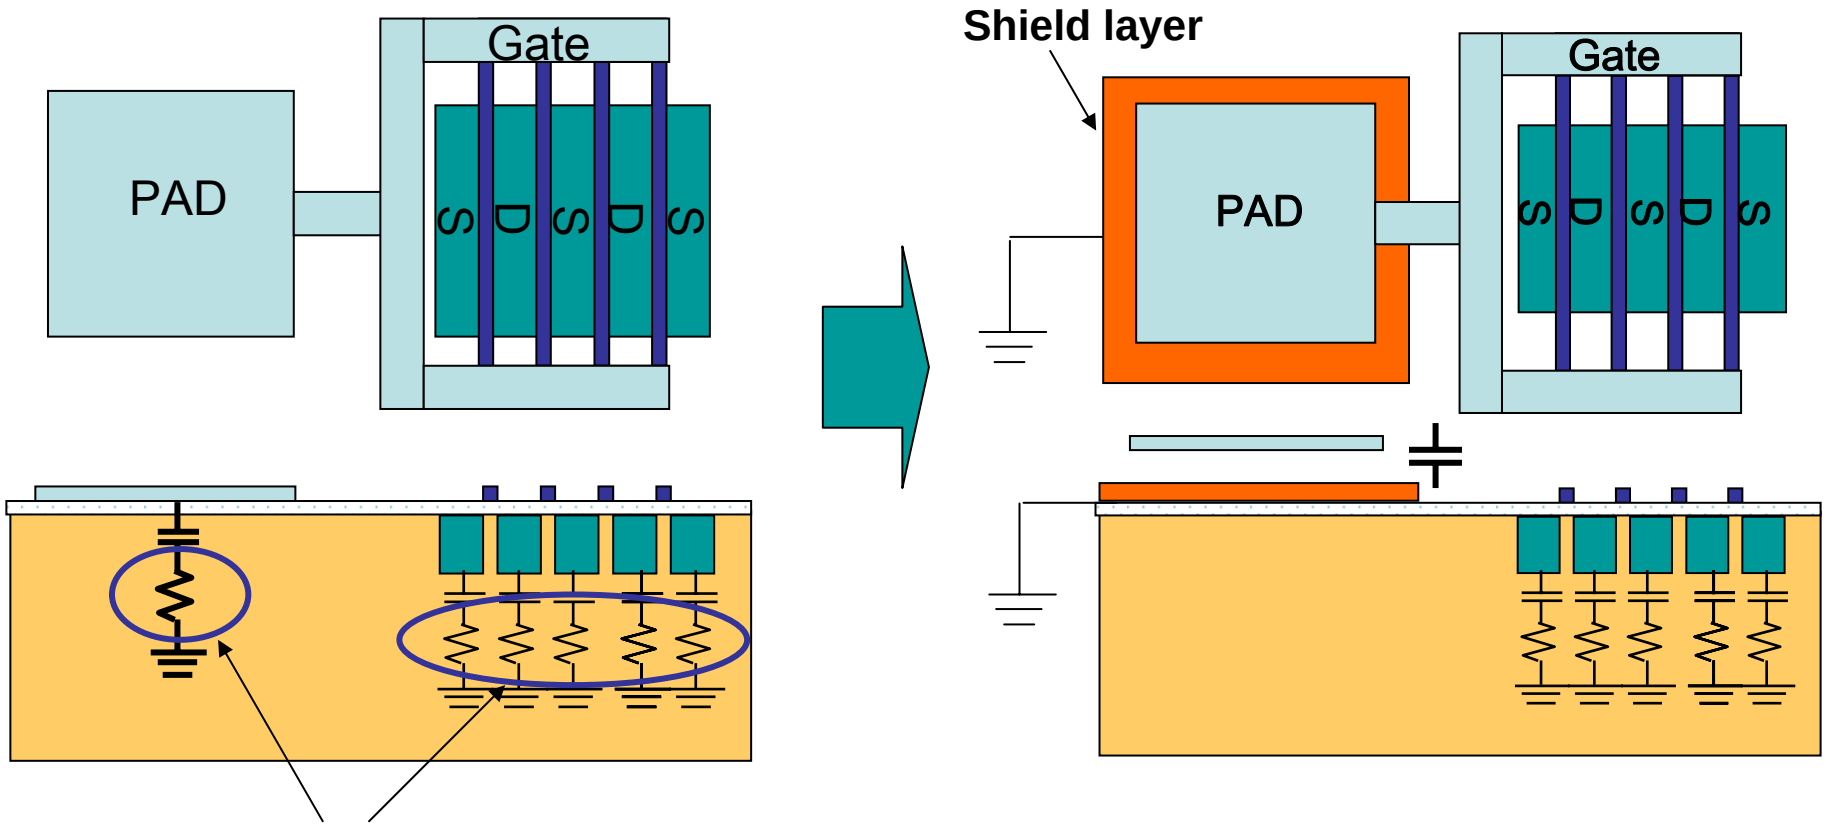
$$\omega_0 = \frac{1}{\sqrt{LC}} \qquad r_o = Q\omega_0 L = \frac{Q}{\omega_0 C}$$

Substrate effect

Substrate should be treated as resistive network.

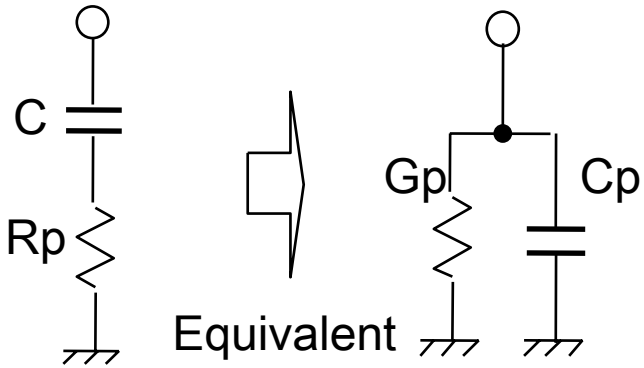
This substrate resistance causes RF power loss and noise generation.

Shielding can reduce this effect.



Power loss in substrate

Very low resistance or high resistance realizes low power loss.

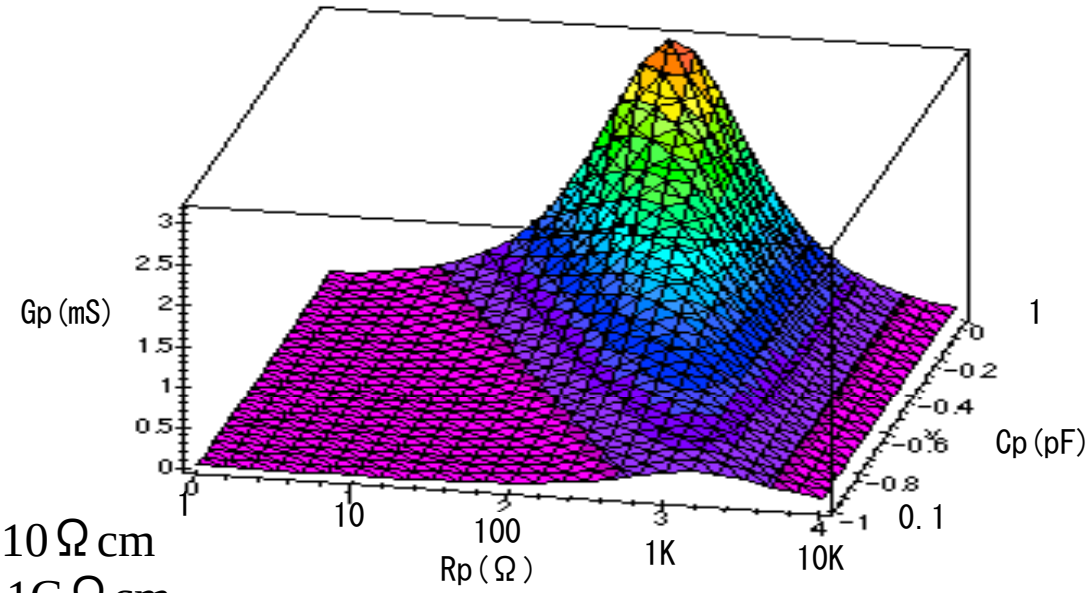


Higher C and moderate R_{sub} results in higher power loss.

$$G_p = \frac{1}{R_p} \cdot \frac{\left(\frac{\omega}{\varpi_p}\right)^2}{1 + \left(\frac{\omega}{\varpi_p}\right)^2}$$

$$C_p = C \frac{1}{1 + \left(\frac{\omega}{\varpi_p}\right)^2}$$

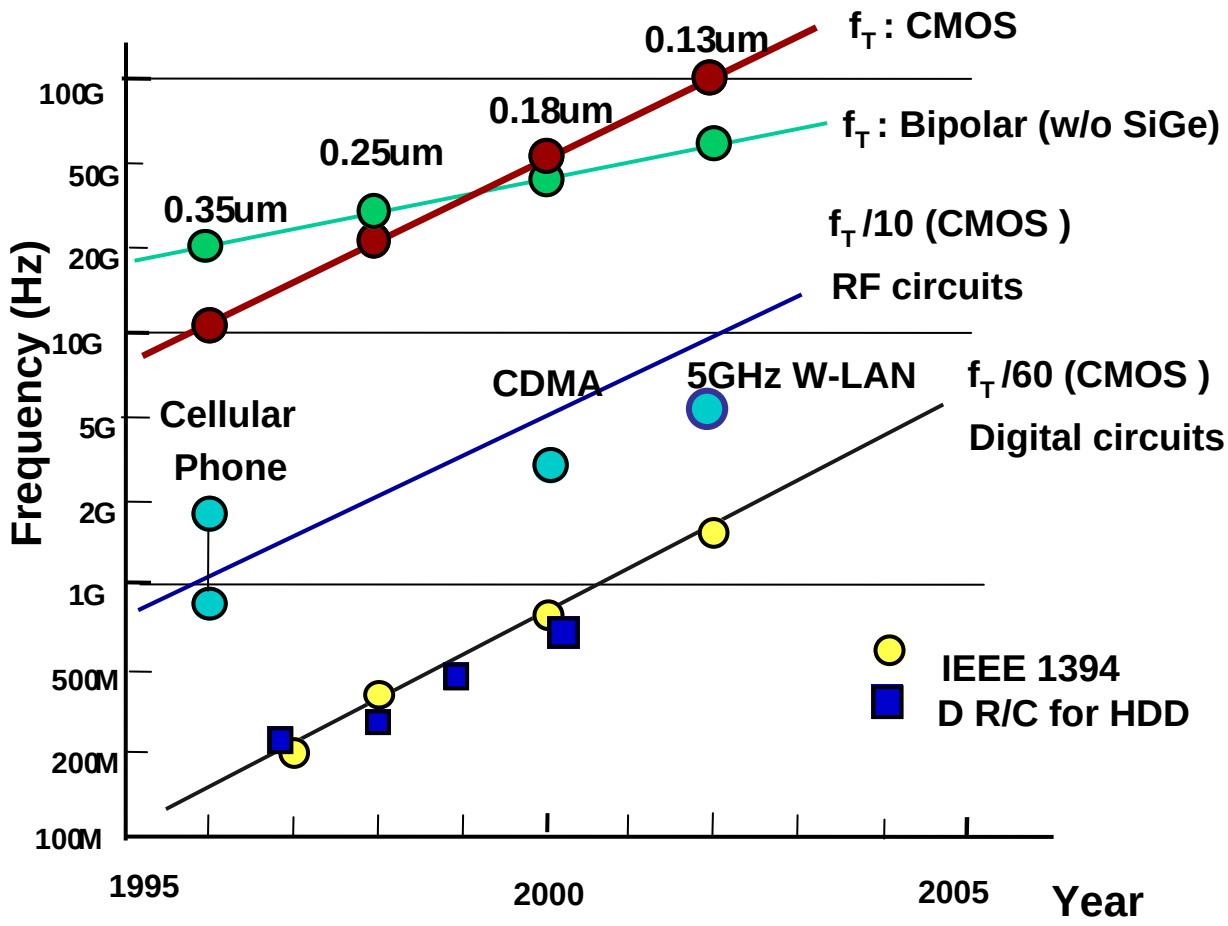
$$\varpi_p = \frac{1}{R_p C}$$



MOS: 10 Ω cm
GaAs: 1G Ω cm

GHz operation by CMOS

The cutoff frequency of MOS becomes higher than that of Bipolar. Over several GHz operations have attained in CMOS technology



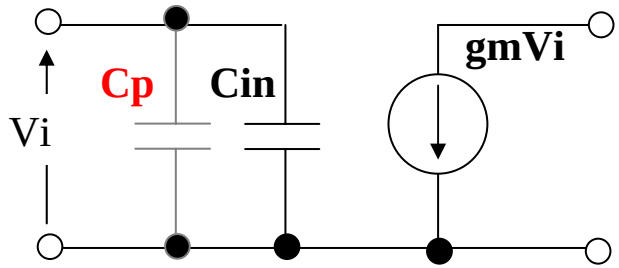
$$f_T \equiv \frac{gm}{2\pi C_{in}}$$

$$f_{Tpeak} \approx \frac{v_{sat}}{2\pi L_{eff}}$$

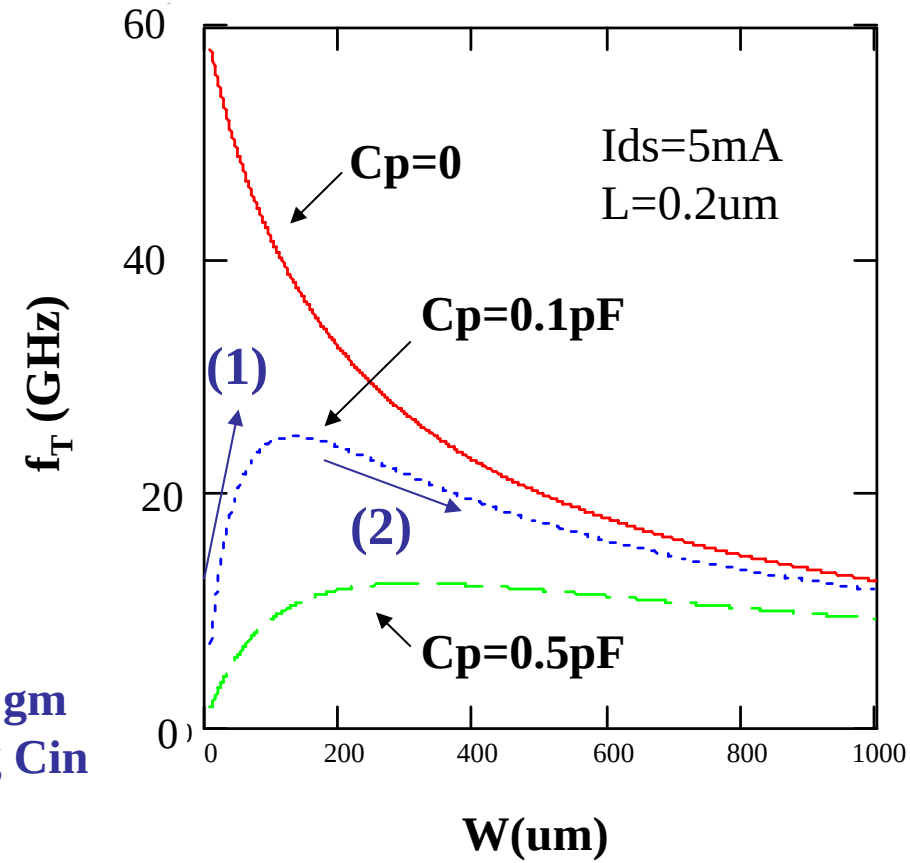
Effect of parasitic capacitance to f_T

f_T of actual circuit is reduced by a parasitic capacitance.
There is an optimum gate width to obtain highest f_T.

$$f_T \equiv \frac{gm}{2\pi(C_{gs}+C_{gd}+C_p)}$$



$C_{in}=C_{gs}+C_{gd}$



Region(1); Increased by increasing gm
Region(2); Decreased by increasing Cin

f_T: MOS vs. Bipolar

Even if f_T of MOS is the same as that of Bipolar,
f_T of MOS is easily lowered by a parasitic capacitance.
Because, gm of MOS is ½ to ¼ of that of Bipolar at the same current.

Small parasitic capacitance is a key for RF CMOS design.

MOS

$$gm \equiv \frac{Ids}{\left(\frac{V_{eff}}{2}\right)}$$

$$V_{eff\,\min} = 2nU_T \quad \text{n: 1.4}$$

Veff/2: 50-100mV (actual ckt.)

$$f_T \equiv \frac{gm}{2\pi Cin}$$

Bipolar

$$gm \equiv \frac{Ic}{U_T}$$

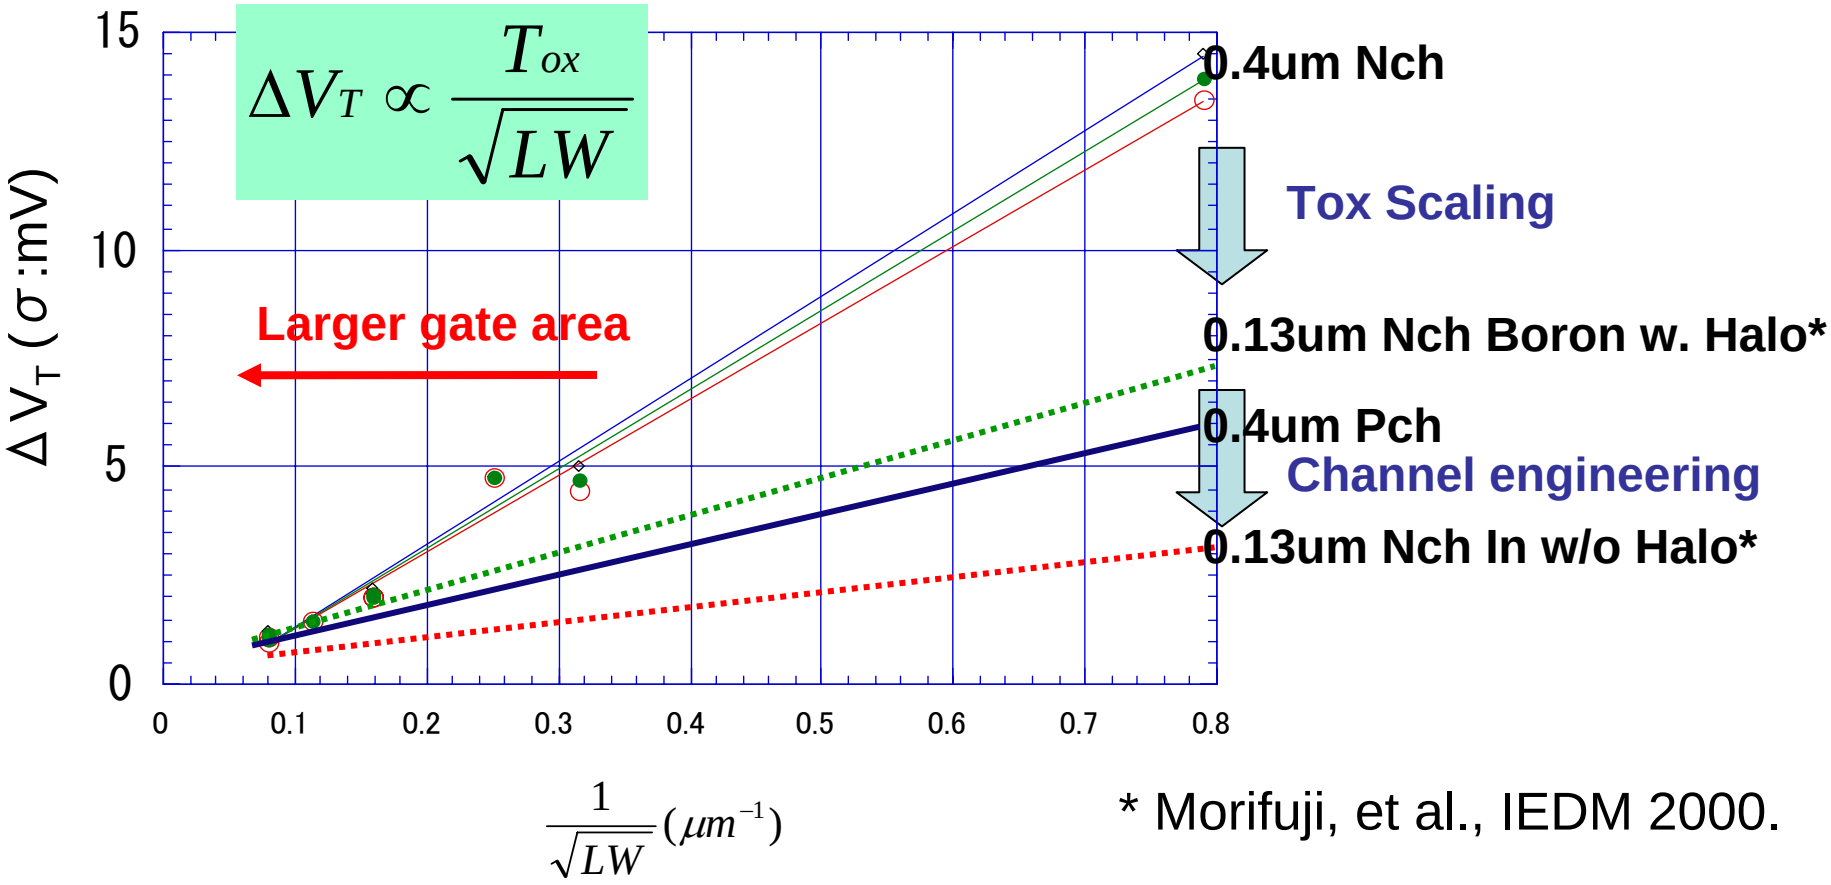
$$U_T \equiv \frac{kT}{q} \approx 26mV$$

$$gm_{CMOS} < \frac{1}{2}, \frac{1}{4} gm_{Bip}$$ （Same operating current）

$$Cin_{CMOS} < \frac{1}{2}, \frac{1}{4} Cin_{Bip}$$ （Same f_T）

V_T mismatch

V_T mismatch degrades accuracy; ADC, OP amp, and Mixer.
Larger gate area is needed for small V_T mismatch.
Scaling and proper channel structure improves mismatch.



* Morifuji, et al., IEDM 2000.

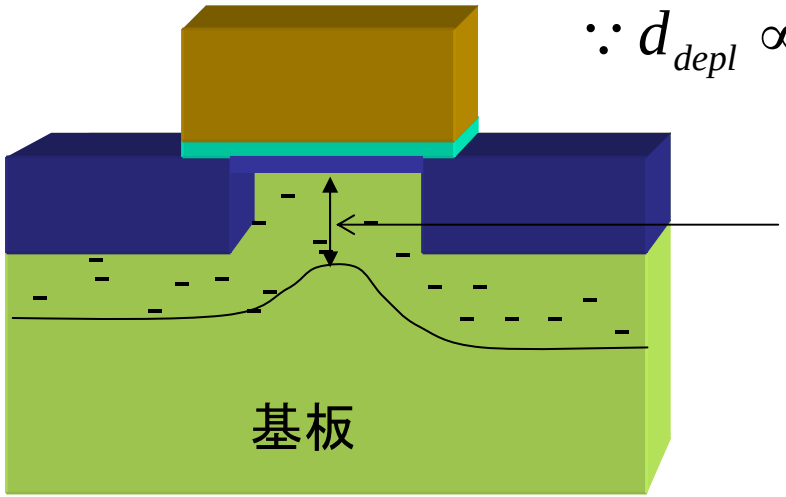
V_T mismatch: Fluctuation of doping

Courtesy of Prof. Taniguchi, Osaka Univ.

$$\Delta V_T = \frac{\Delta Q_{depl}}{C_{ox}} = A t_{ox} \frac{\sqrt{LW d_{depl} N_A}}{LW} = A' t_{ox} \frac{\sqrt[4]{N_A}}{\sqrt{LW}} \approx A_{VT} \frac{t_{ox}}{\sqrt{LW}}$$

$$\because d_{depl} \propto \frac{1}{\sqrt{N_A}}$$

$A_{VT} = 1V$



$$L = W = 0.25\mu m, \quad t_{ox} = 5nm$$

$$\Delta V_T = 20mV$$

T.Mizuno, J.Okamura and A.Toriumi, ”Experimental study o f threshold voltage fluctuation due to statistical variation of channel dopant number in MOSFETs,” IEEE Trans. On Electron Devices, ED-41, 2216 (1994)

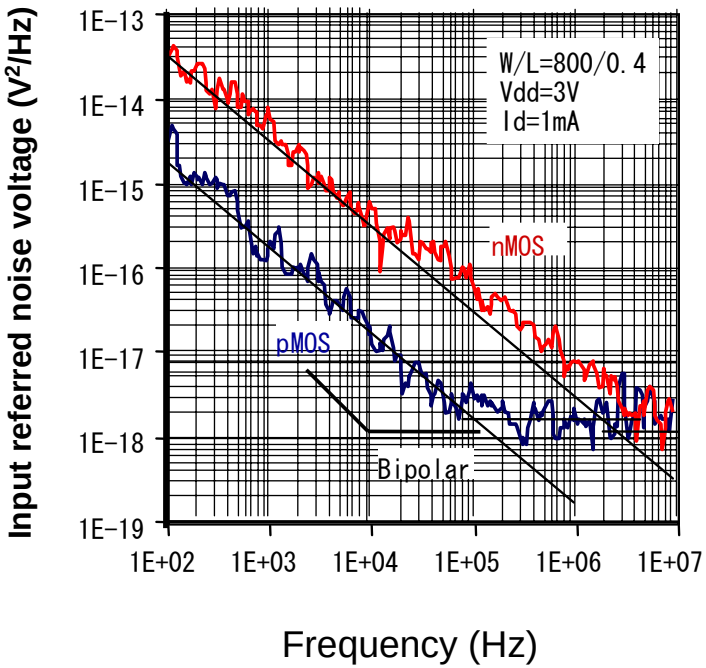
1/f noise

1/f noise of MOS is larger than that of bipolar.

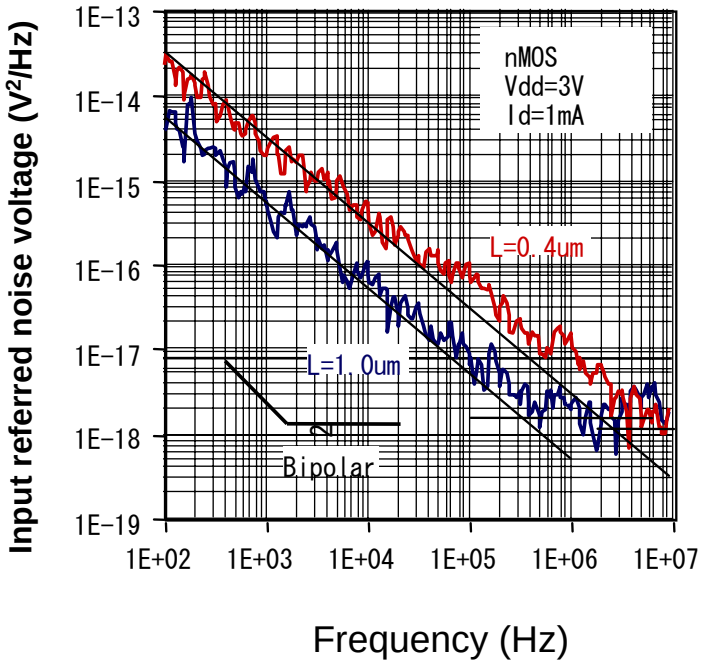
For the lower 1/f noise, the larger gate area is needed.

$$V_{nf}^2 = \frac{S_{vf}}{LW}\frac{\Delta f}{f}, \qquad S_{vf} \propto T_{ox}^2$$

Nch/Pch 0.4um

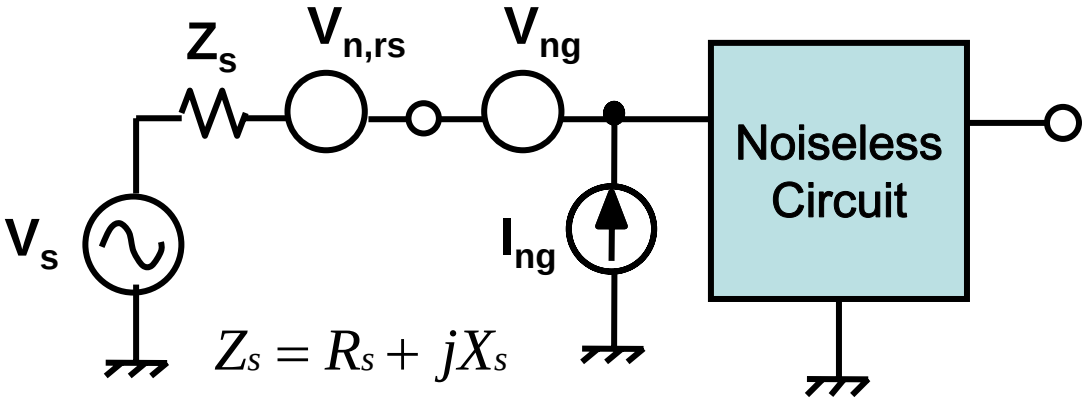


Nch 0.4um/1.0um



Noise figure: General

The lower R_{nv} and G_{ni} realizes the better for a lower noise figure.



$$Z_s = R_s + jX_s$$

$$\overline{V_{ng}{}^2} = 4kTR_{nv}, \quad \overline{I_{ng}{}^2} = 4kTG_{ni}$$

$$F = \frac{\overline{V_{n,rs}^2} + \overline{\left(V_{ng} + Z_s I_{ng}\right)^2}}{\overline{V_{n,rs}^2}} = 1 + \frac{R_{nv}}{R_s} + \frac{\left|Z_s\right|^2 G_{ni}}{R_s} \approx 1 + \frac{R_{nv}}{R_s} + R_s G_{ni}$$

$$R_{sopt} = \frac{\overline{V_{ng}}}{\overline{I_{ng}}} = \sqrt{\frac{R_{nv}}{G_{ni}}} \qquad F_{\min} \approx 1 + 2\sqrt{R_{nv} G_{ni}}$$

Noise figure: MOS transistor

$$F \approx 1 + \frac{R_{nv}}{R_s} + R_s G_{ni}$$

$$R_{nv} = R_g + R_{gs} \qquad R_g = R_{sr} \frac{W_{tot}}{L} \frac{1}{3N^2} \qquad R_{gs} \approx \frac{1}{5gm} \qquad G_{ni} \approx \frac{gm}{5} \left(\frac{\omega_0}{\omega_T} \right)^2$$

$$F \approx 1 + \frac{1}{Rs5gm} + Rs \frac{gm}{5} \left(\frac{\omega_0}{\omega_T} \right)^2 \qquad R_{sopt} \approx \frac{1}{gm} \left(\frac{\omega_T}{\omega_0} \right) = \frac{1}{C_{gs}\omega_0}$$

$$F_{\min} \approx 1 + 2\frac{\omega_0}{\omega_T}$$

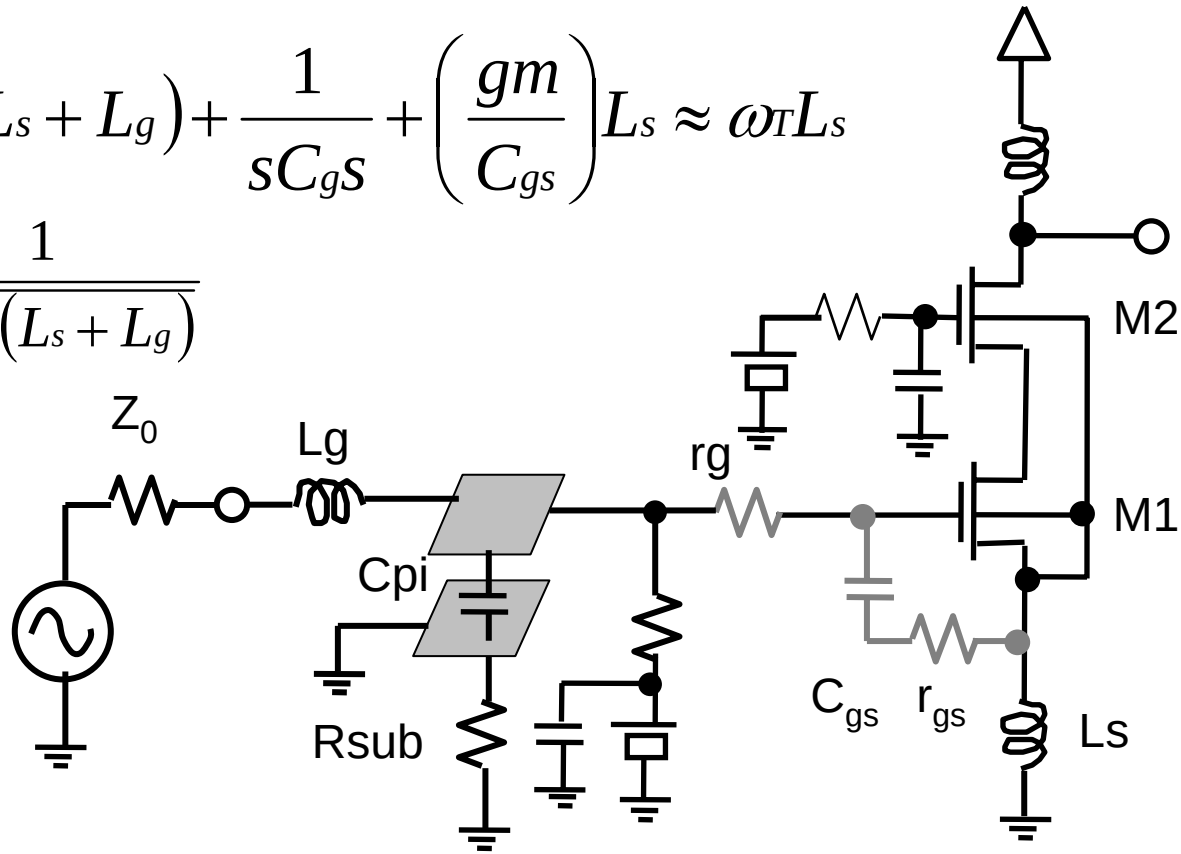
Low noise amplifier design

Narrowband LNA uses inductor degeneration for impedance matching.

Impedance matching

$$Z_{in} \approx s(L_s + L_g) + \frac{1}{sC_gs} + \left(\frac{gm}{C_{gs}}\right)L_s \approx \omega_T L_s$$

$$\omega_0 = \frac{1}{\sqrt{C_{gs}(L_s + L_g)}}$$



Low NF design

$$F \approx 1 + \frac{r_{gs} + r_g}{Z_0} + 4\gamma g_m Z_0 \left(\frac{\omega_0}{\omega_T}\right)^2 \approx 1 + \frac{r_{gs} + r_g}{Z_0}$$

$$r_{gs} \approx \frac{1}{5g_m}$$

Low noise figure

1) Lower the gate resistance

   Dived the gate or lower the gate sheet resistance

$$r_g = R_{sr}\frac{W_{tot}}{L}\frac{1}{3N^2}$$

$$r_g = R_{sr}\frac{W_{tot}}{L}$$

Rsr: Sheet resistance

N : The # of division

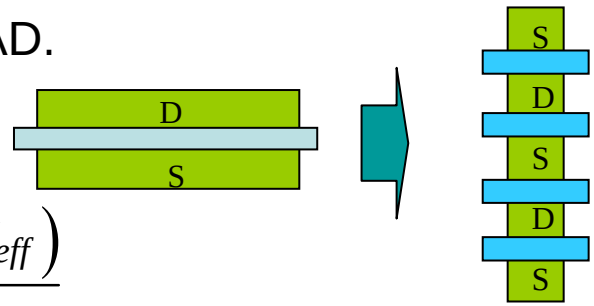
Divide the gate

2) Reduce substrate loss

   Reduce parasitic capacitance

   Use shield technique to the input bonding PAD.

   Use high resistive substrate, if possible.



3) Increase drain current

$$r_{gs} \approx \frac{1}{5g_m} \approx \frac{(V_{eff})}{10I_{ds}}$$

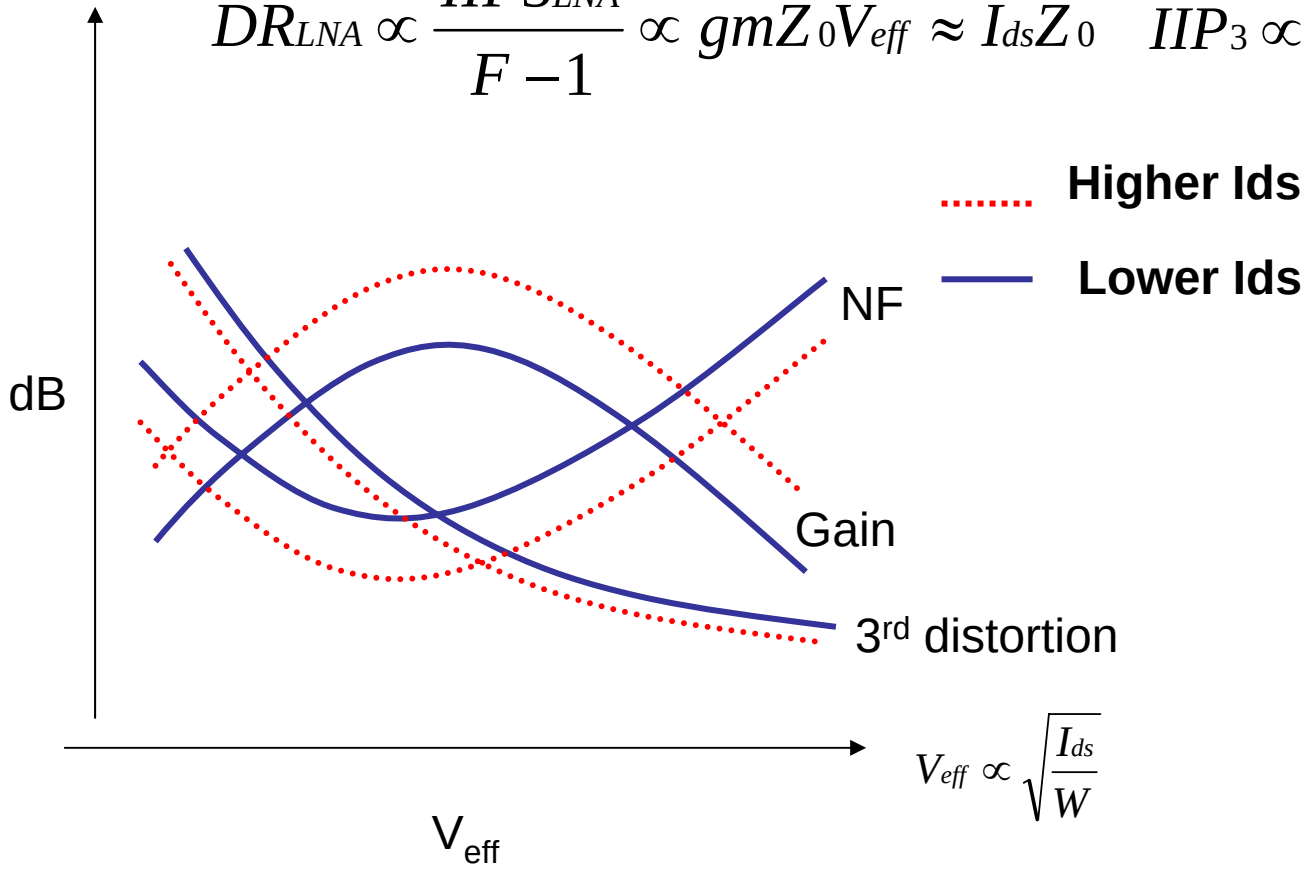
4) Increase Z_0, if possible.

I_{ds} and V_{eff} optimization

Adjust the I_{ds} and V_{eff} for optimization of gain, noise and distortion.

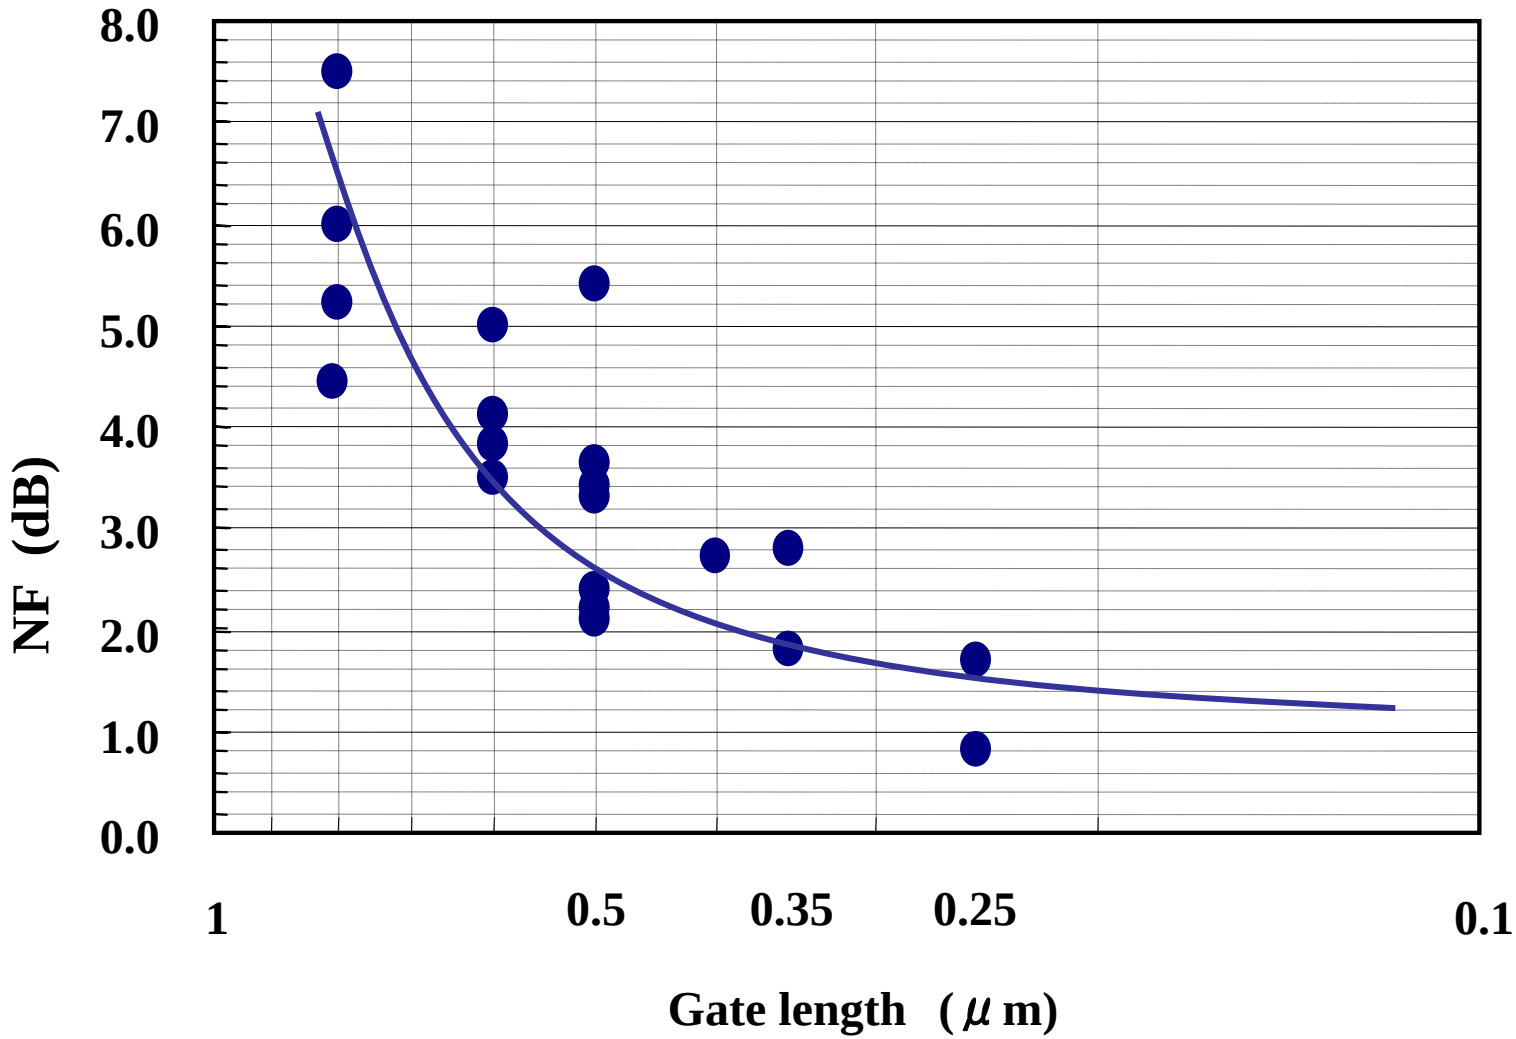
Dynamic range of LNA is proportional to Ids.

$$DR_{LNA} \propto \frac{IIP3_{LNA}}{F-1} \propto gmZ_0V_{eff} \approx I_{ds}Z_0 \quad IIP_3 \propto V_{eff}$$



NF progress in MOS LNA

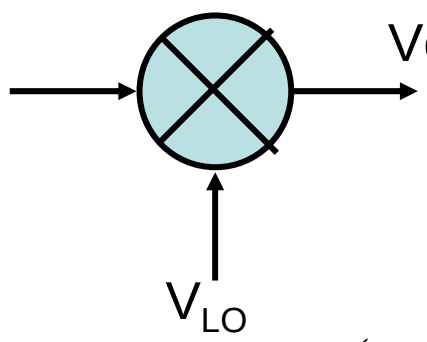
NF of MOS LNA is reaching 1dB.



Mixer

Mixer converts frequency, but image signal is converted to the same frequency.

$$V_s = A_s \cos(\omega_s t)$$



$$V_o = A_s \frac{2}{\pi} \cos((\omega_s \pm \omega_{LO})t)$$

If $V_{LO} >> 4V_{eff}$ (Full swing)

$$V_{LO} = A_{LO} \cos(\omega_{LO} t)$$

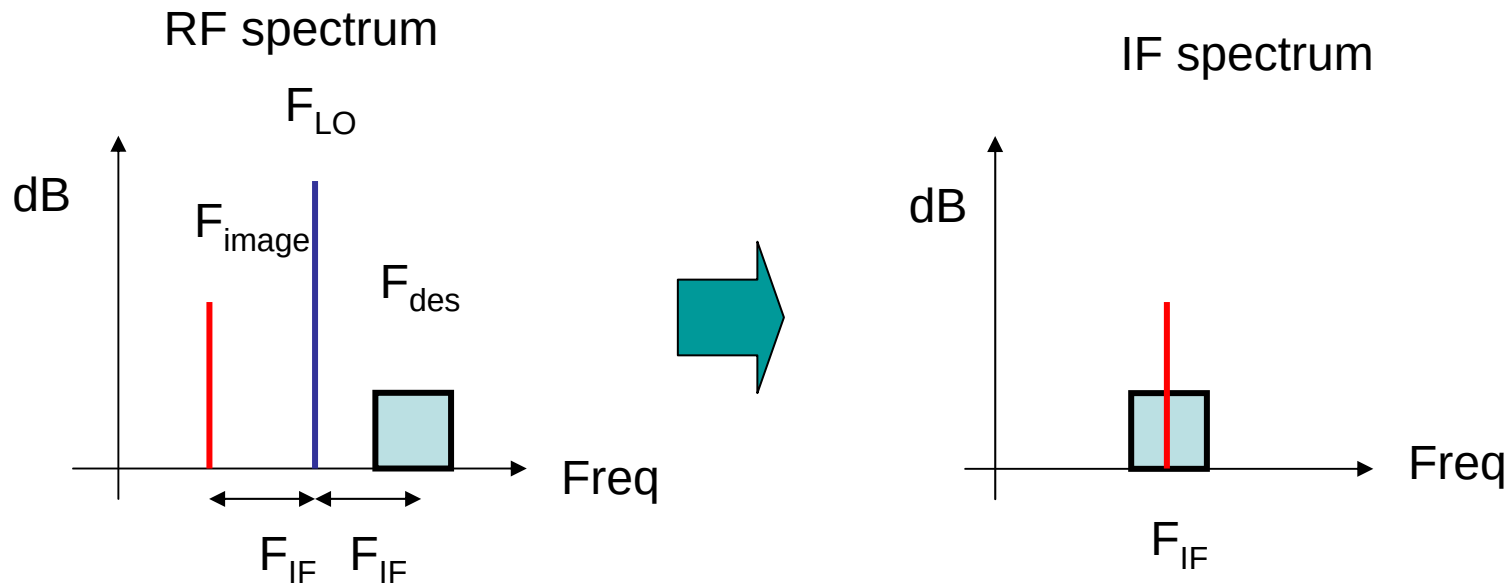


Image-reject mixers

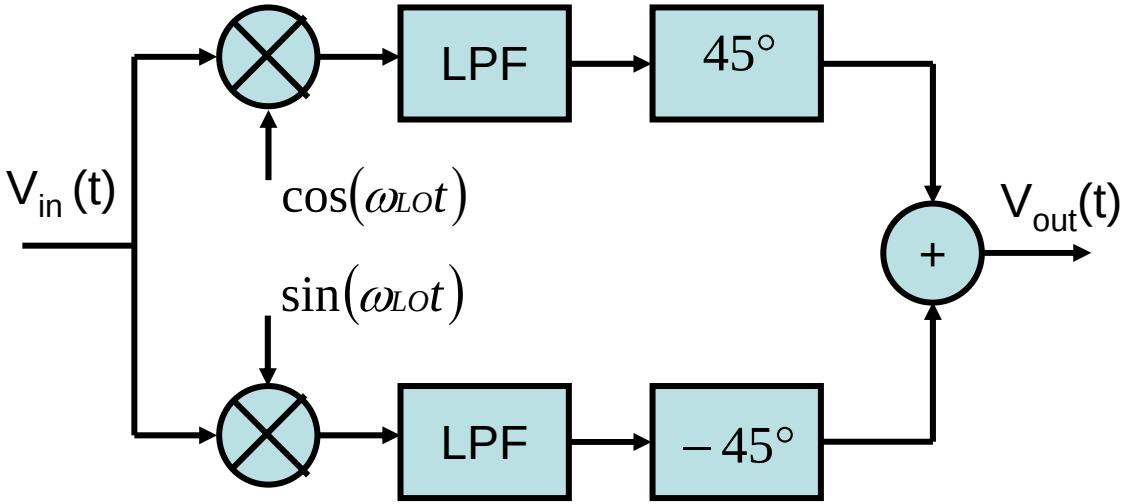
The quadrature mixing realizes image-suppression.
Gain and phase matching is needed.



$$V_{in}(t) = A_{des}\cos(\omega_{des}t) + A_{im}\cos(\omega_{im}t)$$

$$V_{out}(t) = A_{des}A_c\cos(\omega_{IF}t) + A_{im}A_cI_R\cos(\omega_{IF}t)$$

A_c: Conversion gain, I_R: Image rejection

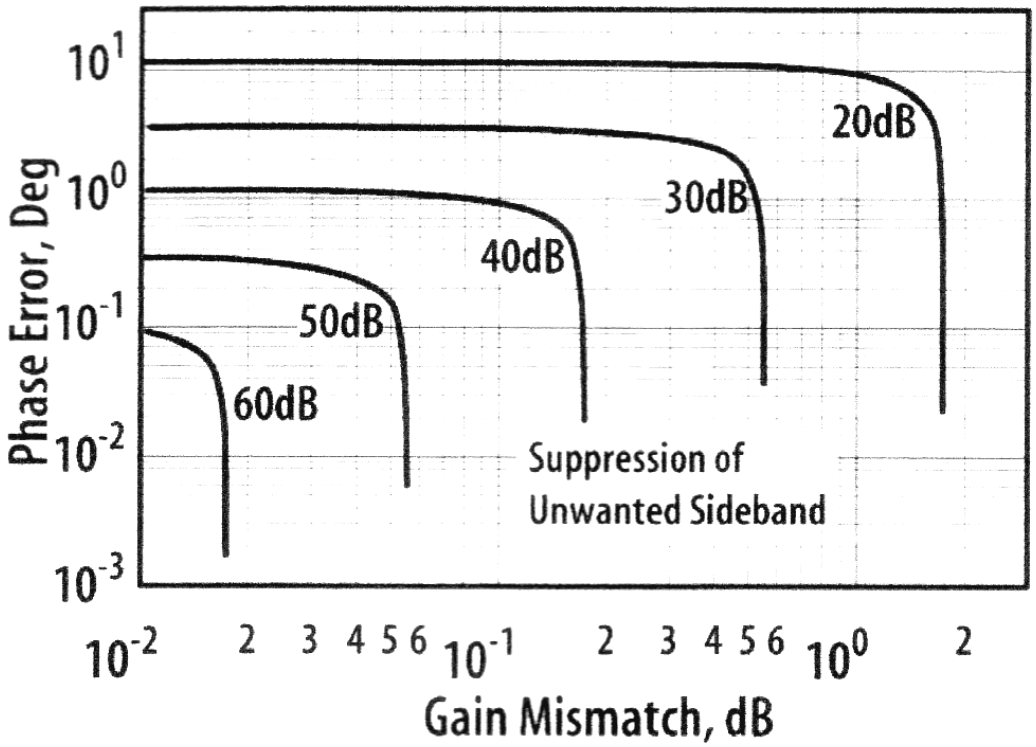
I_R=0 if I/Q phase difference is 90° and Channel conversion gains are equal.

Gain mismatch and phase error

$$\frac{P_{spur}}{P_{desired}} = \frac{1+\gamma^2-2\gamma\cos\phi}{1+\gamma^2+2\gamma\cos\phi}$$

γ : Gain ratio

ϕ :Phase error



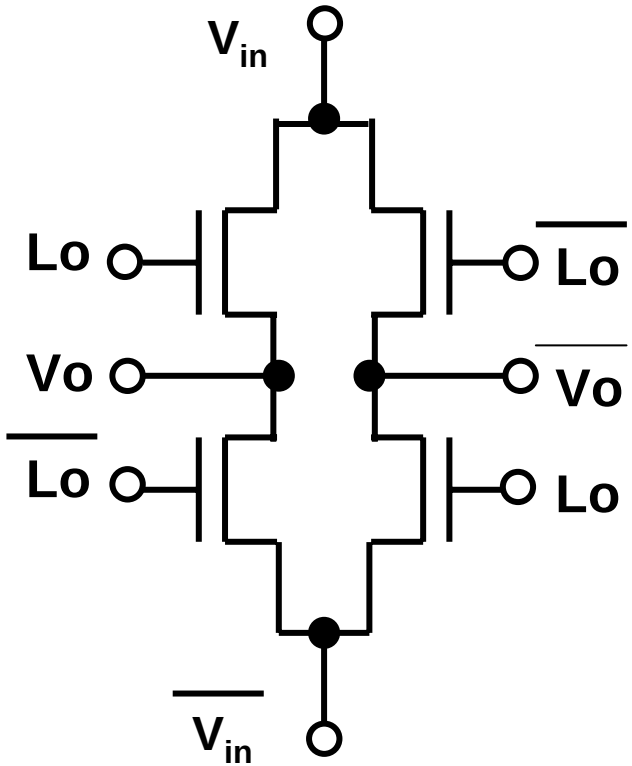
A. Rofougaran, et al., IEEE J.S.C. Vol.33, No.4, April 1998. PP. 515-534.

Passive FET mixer

MOS can realize a passive mixer easily.

Ultimately low power, but take care of isolation.

Passive FET mixer

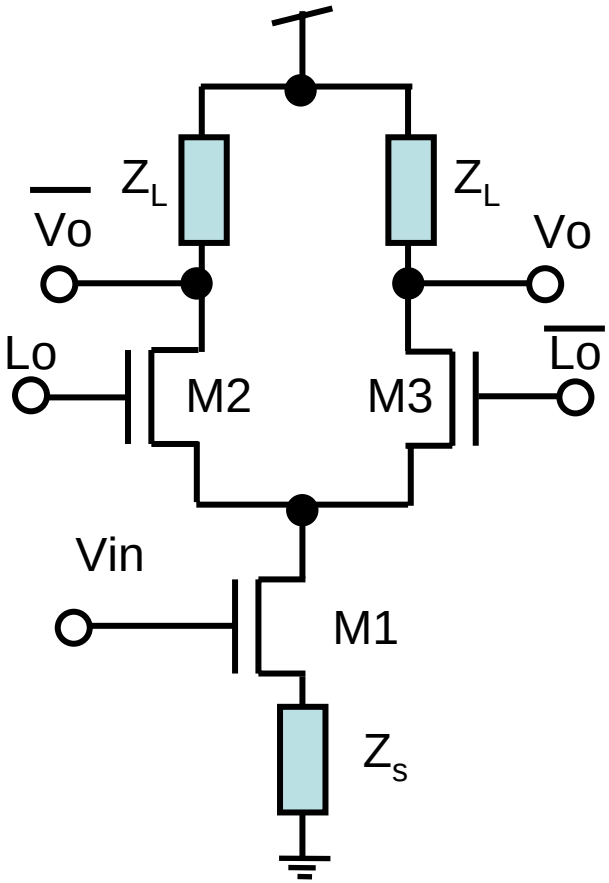


Low power
High linearity
No 1/F noise

No conversion gain
No isolation, Bi-directional

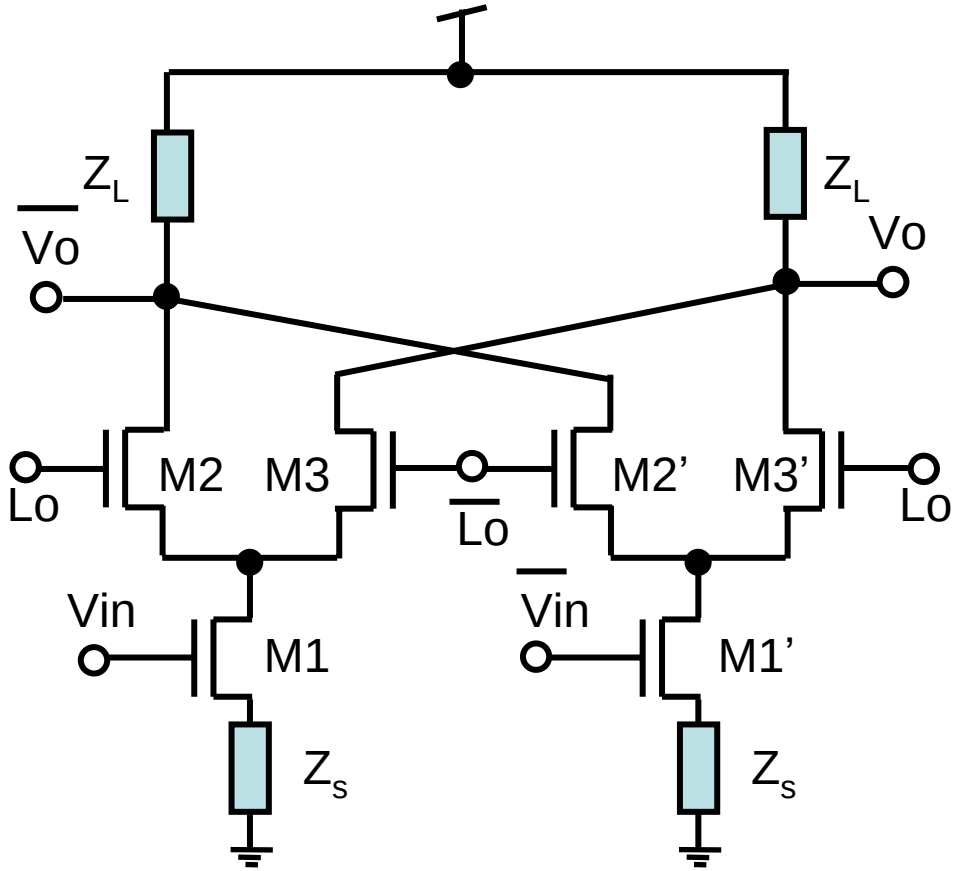
Active mixers

Single balanced mixer



Double balanced mixer

Very small direct feed through and even order distortion



Active mixer design

The larger Ids is needed for high dynamic range and shorter switching time for low 1/f noise.

Mixer gain $G_{mix} = \frac{2}{\pi} gm_1 Z_L, or = \frac{2}{\pi}\frac{Z_L}{Z_s}$ when Z_s is used

R_L: Resistive component in ZL

Thermal noise

$$v_{on}^2 = 8kTR_L\left(1+\frac{2\gamma IR_L}{\pi A_{LO}}+\gamma gm_1 R_L\right) \approx 8kTR_L^2\gamma gm_1$$

$$SSBv_{in}^2 = \frac{v_{on}^2}{\left(\frac{2}{\pi} gm_1 R_L\right)^2} \approx 2\pi^2 kT\frac{\gamma}{gm_1} \cong \pi^2 kT\gamma\frac{V_{eff}}{I_{ds}}$$

$$IIP3 \approx V_{eff}$$

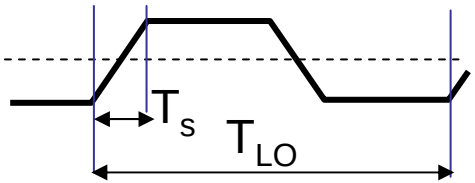
A larger dynamic range needs larger current

1/F noise

1) Switch transistor (M2, M3)

$$v_{n,o} = \frac{4Ts}{T_{LO}} v_{n,sw}$$

$$v_{n,sw}^2 \approx \frac{1}{WL} \propto \frac{1}{Cgs}$$



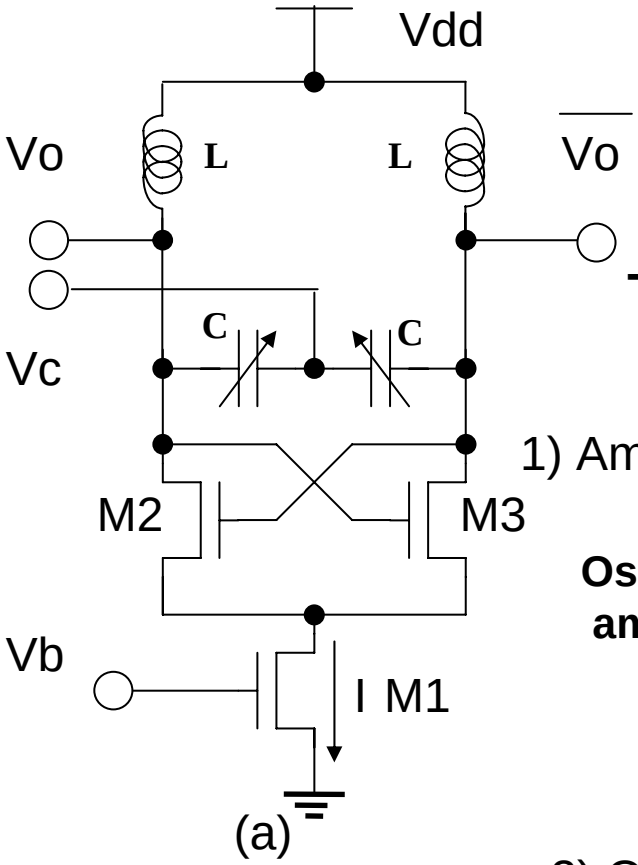
Phase modulation

Shorter switching time or larger T_s/T_{Lo} ratio

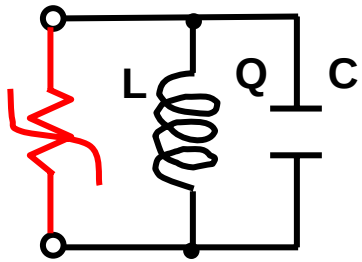
2) Load transistors Directly produces

Oscillator

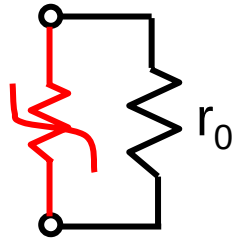
There is an optimum Ids for low phase noise.



-1/gm



-1/gm



$$r_o = Q\omega_0 L = \frac{Q}{\omega_0 C}$$

1) Amplitude condition

Oscillation amplitude $V_{osc} = \frac{4Ir_o}{\pi}$ **Headroom limit** 2Vdd

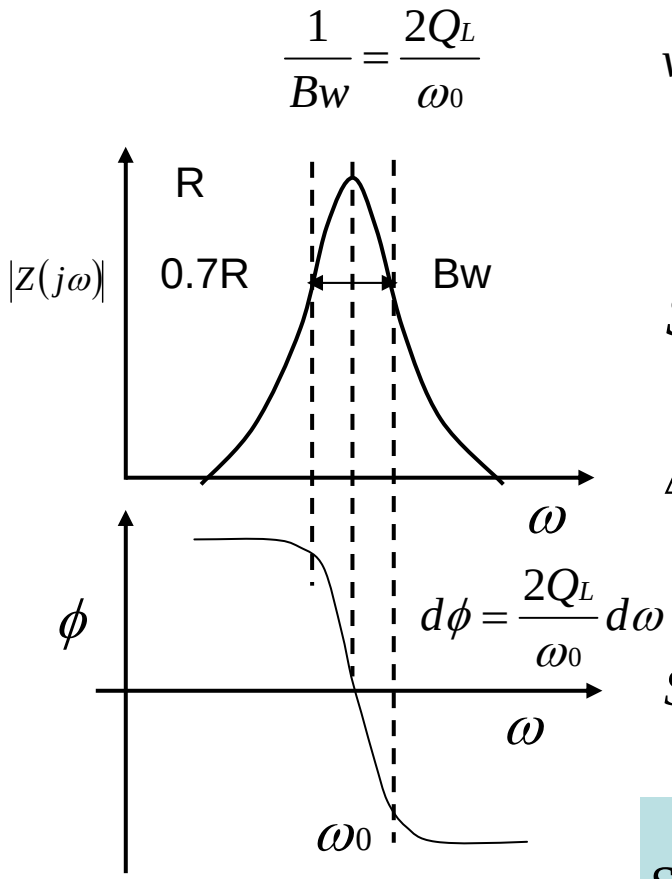
$$I_{opt} = \frac{\pi V_{dd}}{2r_o} = \frac{\pi V_{dd}\omega_o C}{Q}$$

2) Oscillation condition

$$gm_{2,3} > \frac{2}{r_o}, \qquad I > \frac{\omega_o C V_{eff,2,3}}{Q}$$

Phase noise of oscillator

Phase-frequency relation and resonator characteristics determine phase noise.



$$v(t) = A\cos\left[\omega_0 t + \phi(t)\right]$$

$$\omega_m = \frac{d\phi}{dt} = j\omega\phi$$

$$S_\omega(\omega_m) = \omega_m^2 S_\phi(\omega_m)$$

$$\Delta\theta = \frac{\omega_m}{Bw} = \frac{2Q_L}{\omega_0}\omega_m$$

$$S_\omega(\omega_m) = \left(\frac{\omega_0}{2Q_L}\right)^2 S_{\Delta\theta}(\omega_m) \qquad \omega_m < Bw$$

$$S_\phi(\omega_m) = \left(\frac{\omega_0}{2Q_L}\right)^2 \frac{1}{\omega_m^2} S_{\Delta\theta}(\omega_m) = \left(\frac{\omega_0}{2Q_L\omega_m}\right)^2 S_{\Delta\theta}(\omega_m)$$

ω_m : Offset angular frequency

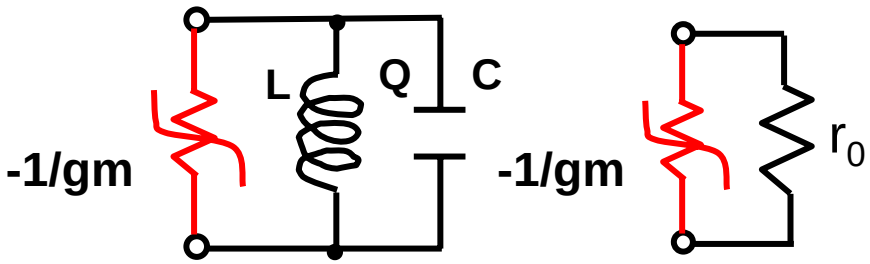
$S_\omega(\omega_m)$:Noise spectrum density on offset angular frequency

$S_\phi(\omega_m)$:Noise spectrum density on phase

$\Delta\theta$ Phase error between in and out

$S_{\Delta\theta}(\omega_m)$:Noise spectrum density on phase error

Phase noise of oscillator



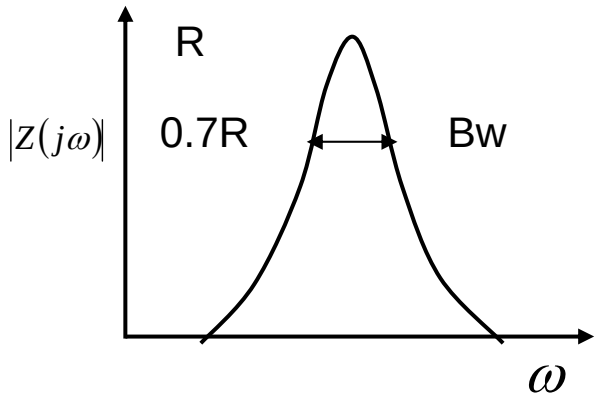
$$Z(\omega_0+\omega_m)\approx j\frac{\omega_0 L}{2\frac{\omega_m}{\omega_0}} \qquad \omega_m << \omega_0$$

(Filter action)

$$Q=\frac{r_0}{\omega_0 L}$$

$$\left|Z(\omega_0+\omega_m)\right|\approx\frac{r_0\omega_0}{2Q\omega_m}$$

$$\frac{1}{Bw}=\frac{2Q}{\omega_0}$$



$$\frac{\overline{v_n^2}}{\Delta f}=\frac{\overline{i_n^2}}{\Delta f}\cdot|Z|^2=4kTr_o\left(\frac{\omega_0}{2Q\omega_m}\right)^2$$

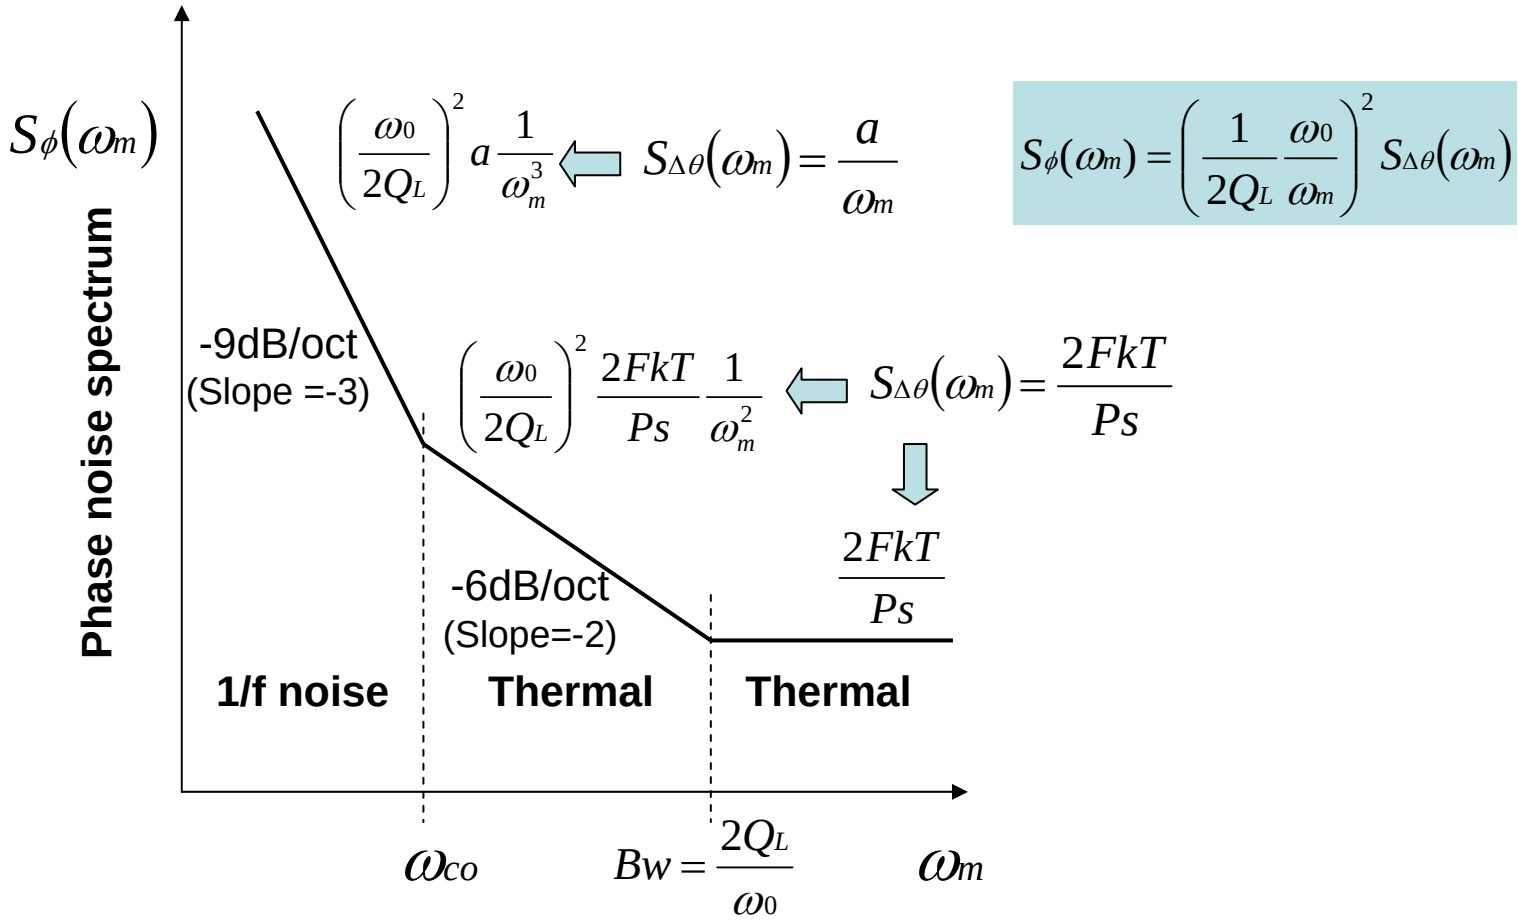
Noise spectrum density

$$L\{\omega_m\}=10\log\left[\frac{2kT}{P_{sig}}\cdot\left(\frac{\omega_0}{2Q\omega_m}\right)^2\right]$$

Phase noise

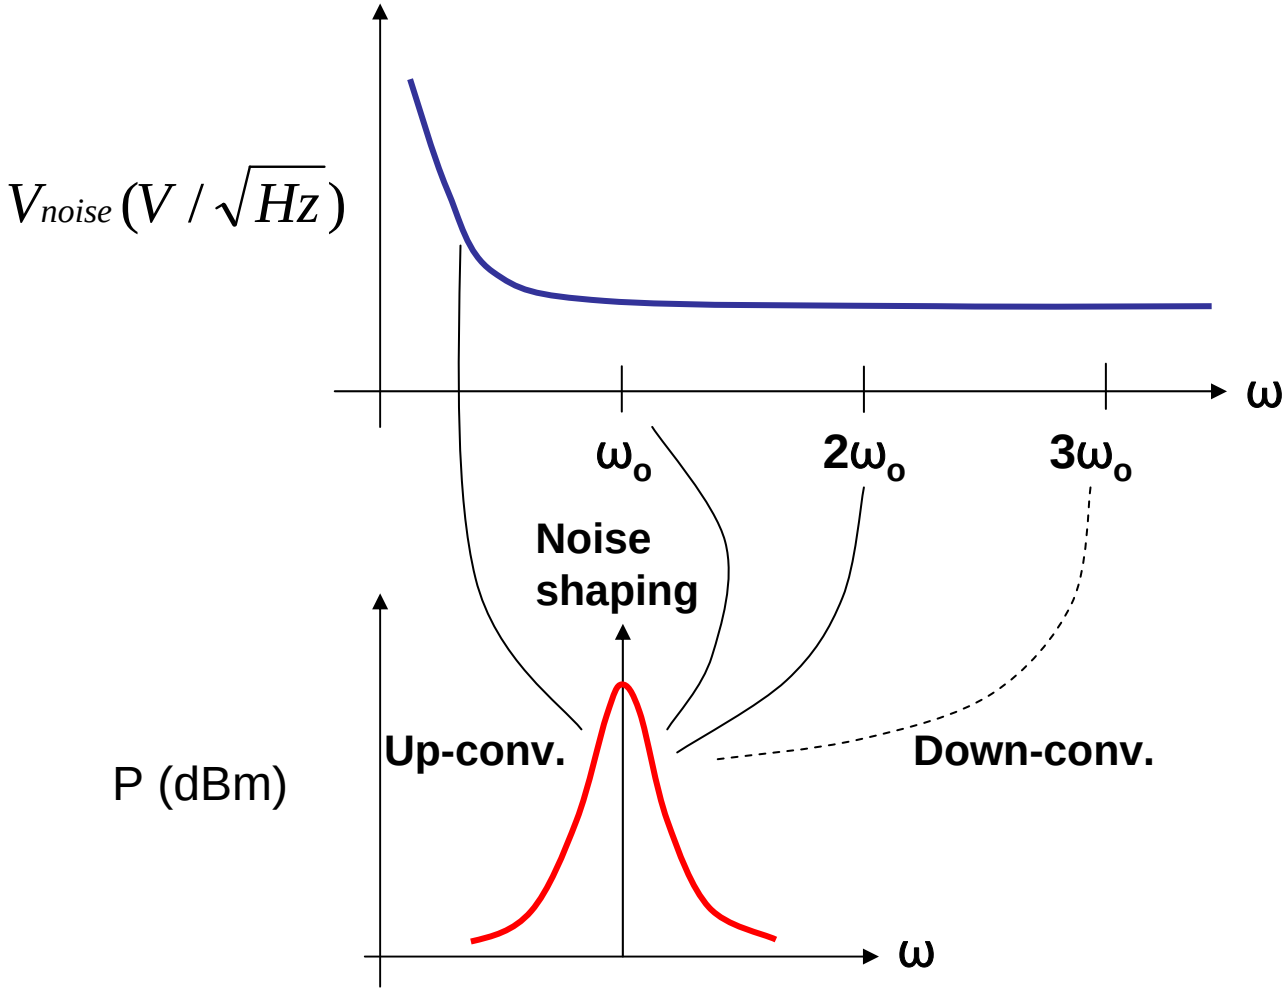
Frequency characteristics of Phase noise in oscillator

1/f noise and thermal noise is converted to $1/f^3$ and$1/f^2$, respectively.



Up and down converted noise

Noises around N*fo are up and down converted to fo.



FoM and minimum phase noise

FoM is basically proportional to Q².

$$FoM = \left(\frac{f_0}{f_m}\right)^2 \frac{1}{L(f_m)V_{dd}I}$$

Fm: Offset frequency
L(fm): Phase noise at offset freq.

$$L(f_m) = \frac{1}{2}\cdot\frac{1}{Q^2}\cdot\left(\frac{f_o}{f_m}\right)^2\cdot\frac{FkT}{P_{RF}} = \frac{1}{2}\cdot\frac{1}{Q^2}\cdot\left(\frac{f_o}{f_m}\right)^2\cdot\frac{FkT}{\left(\frac{V_o^2}{2ro}\right)}$$

F: Noise factor

$$F = 2 + \frac{8\gamma r_o I}{\pi V_o} + \gamma\frac{8}{9}r_o\cdot g_{m1} \qquad I_{opt} = \frac{\pi V_{dd}}{2r_o} = \frac{\pi V_{dd}\omega_o C}{Q} = \frac{\pi V_{dd}}{2Q\omega_o L_{ind}}$$

$$FoM = \frac{4}{\pi}\frac{Q^2}{kT}\frac{1}{2+4\gamma+\frac{32}{9}\gamma\pi\frac{V_{dd}}{V_{eff,1}}} \propto Q^2$$

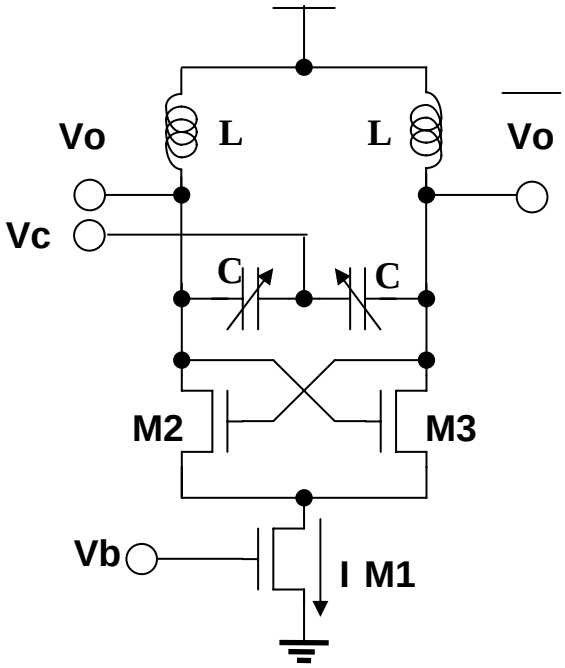
at I_{opt}

Oscillator design

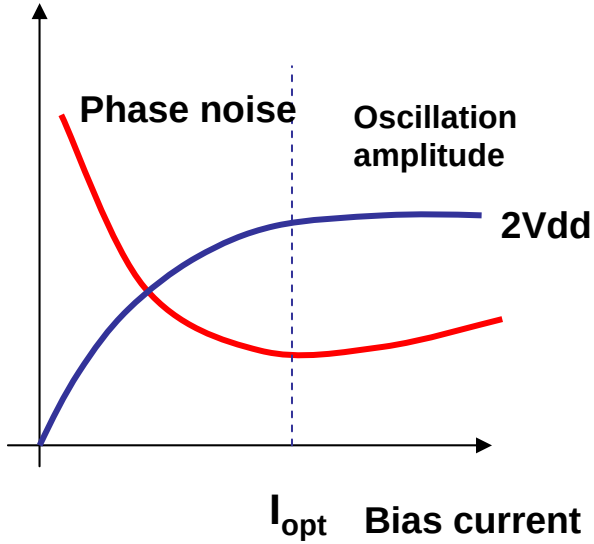
Careful optimization reduces the oscillator phase noise.

$$L_{\min}(f_m) = kT \cdot \frac{\gamma}{V_{dd}} \cdot \frac{\omega_o L_{ind}}{2Q} \cdot \left(\frac{1}{V_{dd}} + \frac{2}{V_{eff,1}} \right) \left(\frac{f_o}{f_m} \right)^2$$

$$L_{\min}(f_m) = kT \cdot \frac{\gamma}{2I_{opt}} \cdot \frac{1}{2Q^2} \cdot \left(\frac{1}{V_{dd}} + \frac{2}{V_{eff,1}} \right) \left(\frac{f_o}{f_m} \right)^2$$



$$I_{opt} = \frac{\pi V_{dd}}{2r_o} = \frac{\pi V_{dd} \omega_o C}{Q} = \frac{\pi V_{dd}}{2Q\omega_o L_{ind}}$$



Larger V_{dd}
Large V_{eff1}, but take care of V_o reduction
Large L_1, W_1 to reduce 1/f noise
Enough W/L for M2, M3
Higher Q
Larger QL_{ind} for Lower I_{opt}

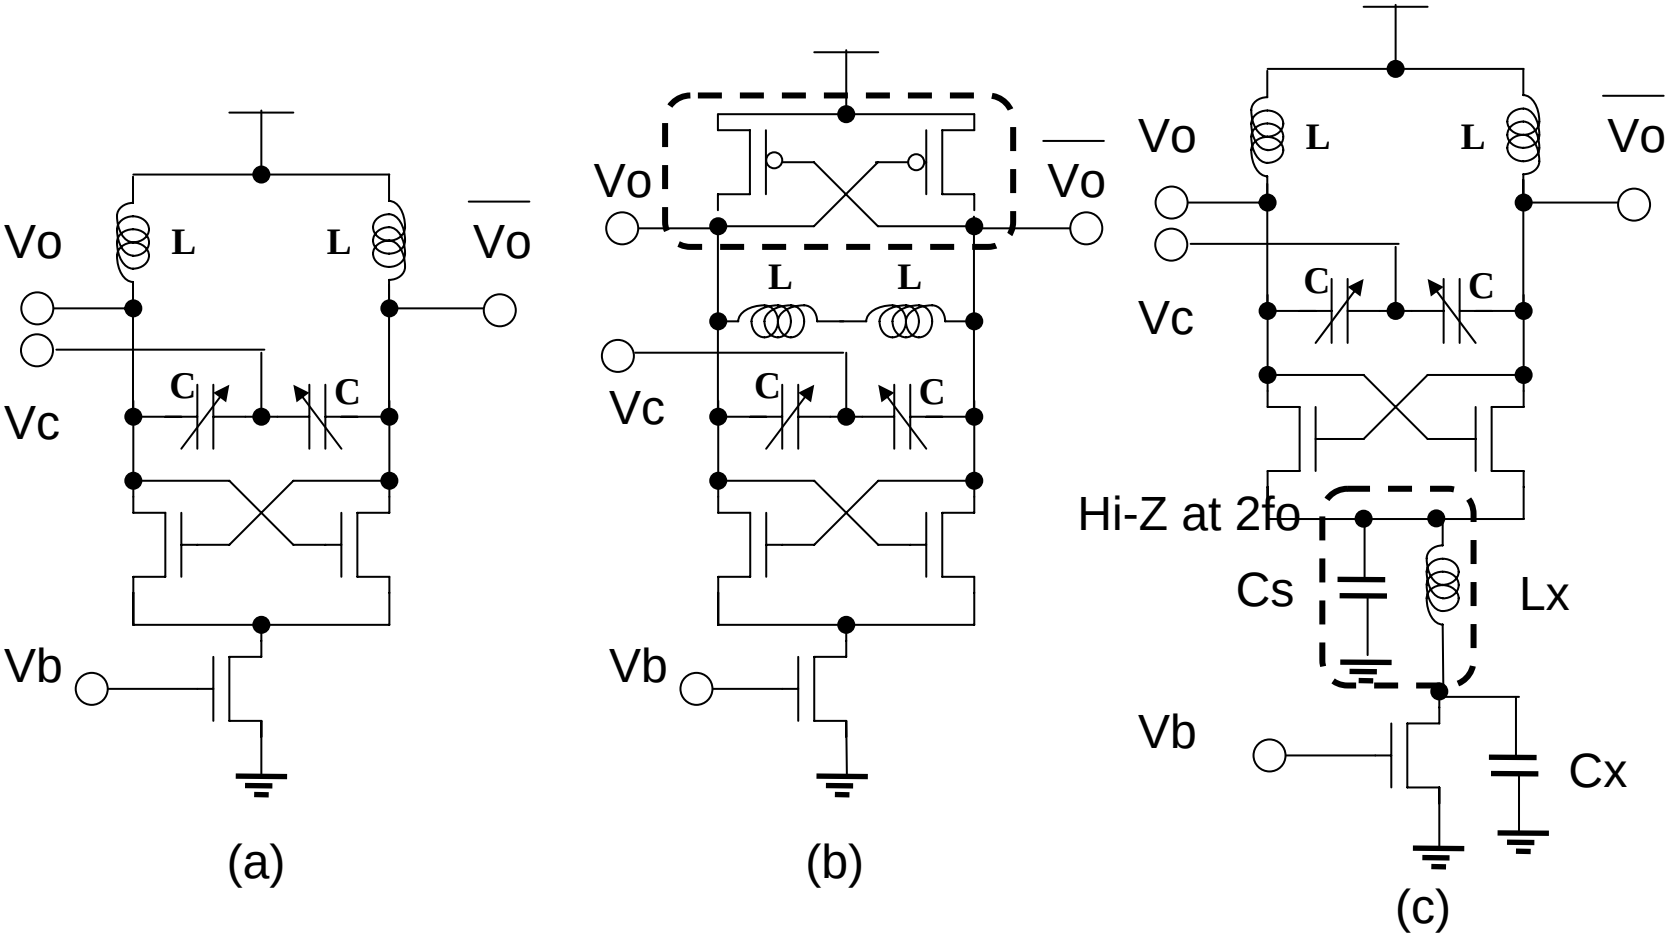
CMOS oscillator circuits

E. Hegazi, ISSCC 2001

Basic

Low power (gm is higher)

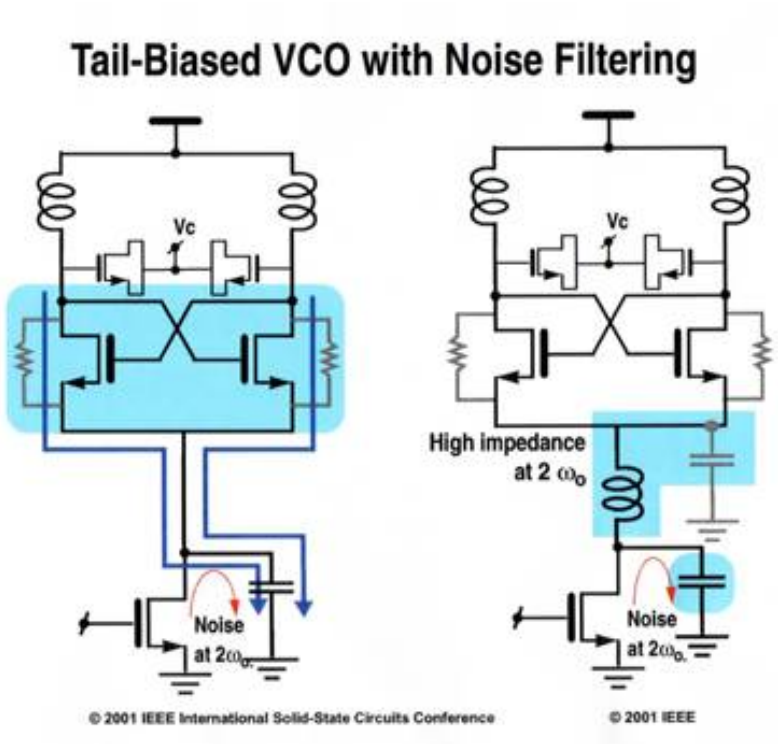
Low noise by filtering

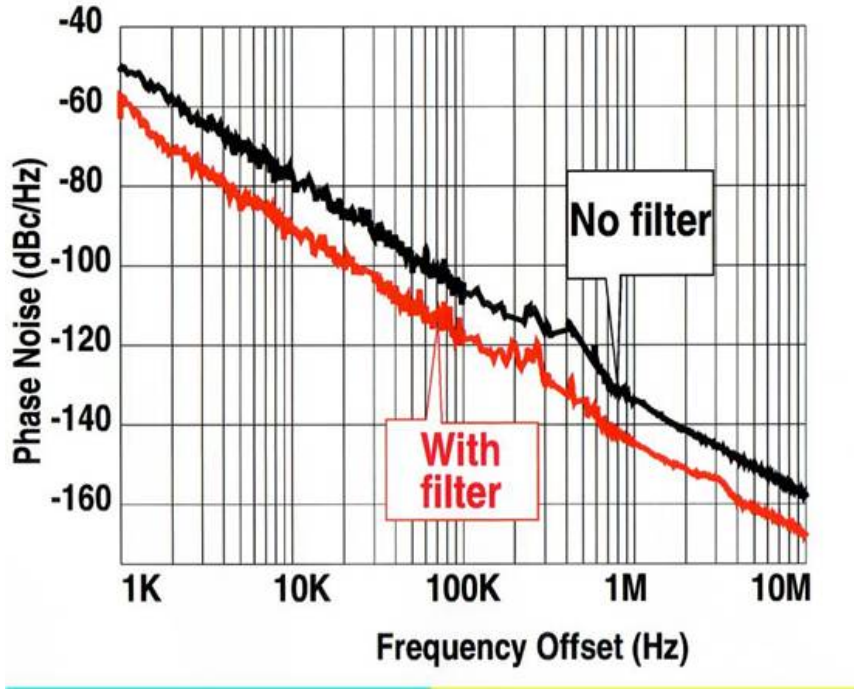


Filtering of $2f_o$ component in OSC.

Noise filtering of $2f_o$ component reduces the OSC phase noise to -10dB.

E. Hegazi, ISSCC 2001





Oscillator phase noise progress

Phase noise in CMOS oscillator becomes lower than that of bipolar.

An In-Line RF Wattmeter

Considerable attention was devoted to the resistance-type SWR bridge in the preceding section because it is the simplest type that is capable of adequate accuracy in measuring standing-wave ratio. Its disadvantage is that it must be operated at a very low power level, and thus is not suitable for continuous monitoring of the SWR in actual transmission. To do this the instrument must be capable of carrying the entire power output of the transmitter, and should do it with negligible loss. An RF wattmeter meets this requirement.

It is neither costly nor difficult to build an RF wattmeter. And, if the instrument is equipped with a few additional components, it can be switched to read reflected power as well as forward power. With this feature the instrument can be used as an SWR meter for antenna matching and Transmatch adjustments. The wattmeter shown in Figs 9 through 12 meets these requirements. The instrument uses a directional type of coupler for sampling the energy on the transmission line. The indicator sensitivity of this instrument is not related to frequency, as is the case with some types of directional couplers. This unit may be calibrated for power levels as low as 1 watt, full scale, in any part of the HF spectrum. With suitable calibration, it has good accuracy over the 3-30 MHz range. It is built in two parts, an RF head for inserting in the coaxial transmission line, and a control-meter box which can be placed in any location where it can be operated conveniently. Only direct current flows in the cable connecting the two pieces.

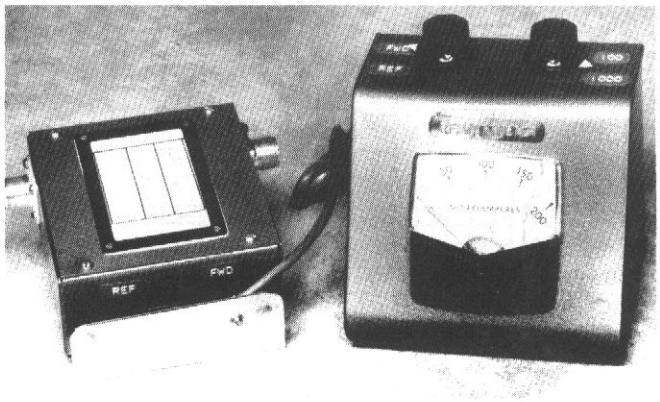

Fig 9—The RF wattmeter consists of two parts, the RF head (left), and the control-meter box (right). The paper scale affixed to the RF head contains the calibration information which appears in Fig 10.

Design Philosophy

See the circuit of Fig 10. The transmission line center conductor, W1, passes through the center of a toroid core and becomes the primary of T1. The multiturn winding on the core functions as the transformer secondary. Current flowing on W1 induces a voltage in the secondary which causes a current to flow through resistors R1 and R2. The voltage drops across these resistors are equal in amplitude, but 180° out of phase with respect to common or ground. They are thus, for practical purposes, respectively in and out of phase with the line current. Capacitive voltage dividers, C1-C3 and C2-C4, are connected across the line to obtain equal-amplitude voltages *in phase* with the line voltage, the division ratio being adjusted so that these voltages match the voltage drops across R1 and R2 in amplitude. (As the current/voltage ratio in the line depends on the load, this can be done only for a particular value of load impedance. Load values chosen for this standardization are pure resistances that match the characteristic impedance of the transmission line with which the bridge is to be used, 52 or 75 ohms usually.) Under these conditions, the voltages rectified by D1 and D2 represent, in the one case, the vector *sum* of the voltages caused by the line current and voltage, and in the other, the vector *difference*. With respect to the resistance for which the circuit has been set up, the sum is proportional to the forward component of a traveling wave such as occurs on a transmission line, and the difference is proportional to the reflected component.

Component Selection

R1 and R2 should be selected for the best null reading when adjusting the bridge into a resistive 52- or 75-ohm load. Normally, the value will be somewhere between 10 and 47 ohms. The 10-ohm value worked well with the instruments shown here. Half-watt composition resistors are suitable to 30 MHz. R1 and R2 should be as closely matched in resistance as possible. Their exact value is not critical, so an ohmmeter may be used to match them.

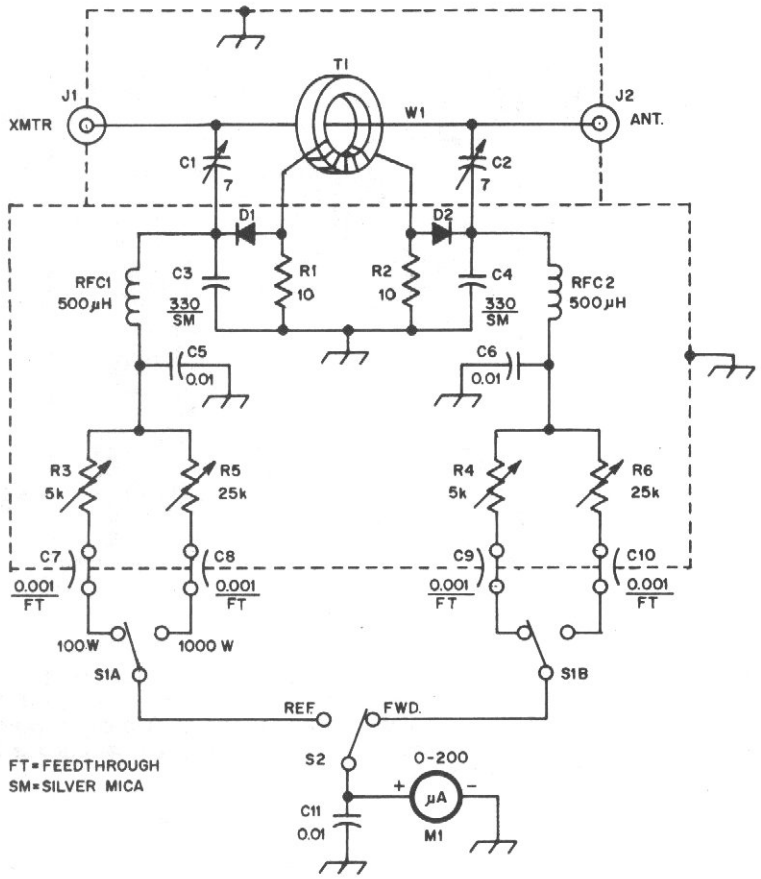
Ideally, C3 and C4 should be matched in value. Silver-mica capacitors are usually close enough in tolerance that special selection is not required, providing there is enough leeway in the ranges of C1 and C2 to compensate for any difference in the values of C3 and C4.

Diodes D1 and D2 should also be matched for best results. An ohmmeter can be used to select a pair of diodes having forward dc resistances within a few ohms of being the same. Similarly, the back resistances of the diodes can be matched. The matched diodes will help to assure equal meter readings when the bridge is reversed. (The bridge should be perfectly bilateral in its performance characteristics.) Germanium diodes should be used to avoid misleading results when low values of reflected power are present during antenna adjustments. The SWR can appear to be perfect when actually it isn't. The germanium diodes conduct at approximately 0.3 volt, making them more suitable for low-power readings than silicon diodes (conduction at 0.7 V).

Any meter having a full-scale reading between 50 μA and 1 mA can be used at M1. The more sensitive the meter, the more difficult it will be to get an absolute reflected-power reading of zero. Some residual current will flow in the bridge circuit no matter how carefully the circuit is balanced, and a sensitive instrument will indicate this current flow. Also, the more sensitive the meter, the larger will have to be the calibrating resistances, R3 through R6, to provide high-power readings. A 0-200 μA meter represents a good compromise for power ranges between 100 and 2000 watts.

Construction

It is important that the layout of any RF bridge be as symmetrical as possible if good balance is to be had. The circuit-board layout of Fig 12 meets the requirement for this instrument. The input and output ports of the equipment should be isolated from the remainder of the circuit so that only the sampling circuits feed voltage to the bridge. A shield across the end of the box which contains the input and output jacks and W1 is necessary. If stray RF gets into the bridge



WATTS	M1	WATTS
100	200	1000
90	180	900
80	170	800
70	155	700
60	145	600
50	125	500
40	105	400
30	85	300
20	65	200
10	40	100
5	20	50

Fig 10—Schematic diagram of the RF wattmeter. A calibration scale for M1 is shown also. Fixed-value resistors are ½-watt composition. Fixed-value capacitors are disc ceramic unless otherwise noted. Decimal-value capacitances are in microfarads. Others are picofarads. Resistance is in ohms; k = 1000.

C1, C2—1.3- to 6.7-pF miniature trimmer (E. F. Johnson 189-502-4, available from Newark Electronics, Chicago, Illinois)

C3-C11, incl—Numbered for circuit-board identification.

D1, D2—Matched small-signal germanium diodes, 1N34A, etc (see text).

J1, J2—Chassis-mount coax connector of builder's choice. Type SO-239 used here.

M1—0-200 μA meter (Triplett type 330-M used here).

R1, R2—Matched 10-Ω resistors (see text).

R3, R4—5-kΩ printed-circuit carbon control (IRC R502-B).

R5, R6—25-kΩ printed-circuit carbon control (IRC R242-B).

RFC1, RFC2—500-μH RF choke (Millen 34300-500 or similar).

S1—DPDT single-section phenolic wafer switch (Mallory 3222J).

S2—SPDT phenolic wafer switch (Centralab 1460).

T1—Toroidal transformer; 35 turns of no. 26 enam wire to cover entire core of Amidon T-68-2 toroid (available from Amidon Assoc or Radiokit).

W1—Numbered for text discussion.

circuit, it will be impossible to obtain a complete zero reflected-power reading on M1 even though a 1:1 SWR exists.

All of the RF head components except J1, J2 and the feedthrough capacitors are assembled on the board. The board is held in place by means of a homemade aluminum L bracket at the end nearest T1. The circuit board end nearest the feedthrough capacitors is secured with a single no. 6 spade bolt. Its hex nut is outside the box, and is used to secure a solder lug which serves as a connection point for the ground braid in the cable which joins the control box to the RF head.

T1 fits into a cutout area of the circuit board. A 1-inch long piece of RG-8 coax is stripped of its vinyl jacket and shield braid, and is snug-fit into the center hole of T1. The inner conductor is soldered to the circuit board to complete the W1 connection between J1 and J2.

The upper dashed lines of Fig 10 represent the shield partition mentioned above. It can be made from flashing copper or thin brass.

The control box, a sloping-panel utility cabinet measuring 4 × 5 inches, houses S1, S2 and the meter, M1. Four-conductor shielded cable—the shield serving as the common lead—is used to join the two pieces. There is no reason the entire instrument cannot be housed in one container, but it is sometimes awkward to have coaxial cables attached to a unit that occupies a prominent place in the operating position. When built as shown, the two-piece instrument permits the RF pickup head to be concealed behind the transmitter, while the control head can be mounted where it is accessible to the operator.

Adjustment

Perhaps the most difficult task faced by the constructor

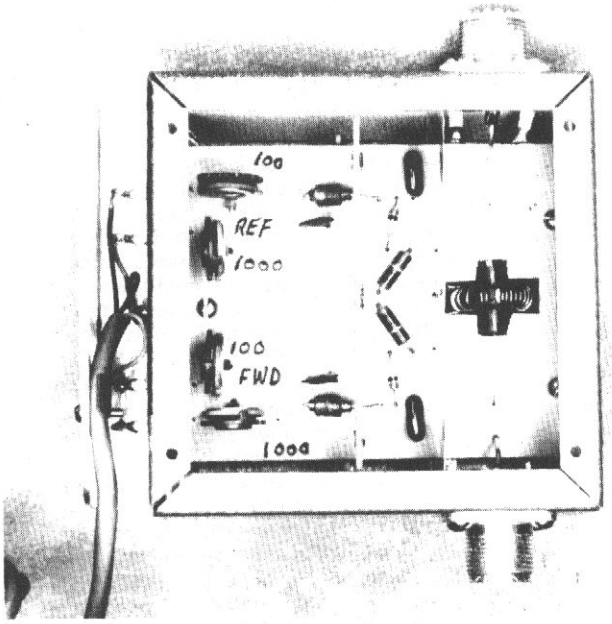


Fig 11—Top view of the RF head for the circuit of Fig 10. A flashing-copper shield isolates the primary RF line and T1 from the rest of the circuit. The second shield (thicker) is not required and can be eliminated from the circuit. If a 2000-watt scale is desired, fixed-value resistors of approximately 22 kΩ can be connected in series with high-range printed-circuit controls. Instead, the 25-kΩ controls shown here can be replaced by 50-kΩ units.

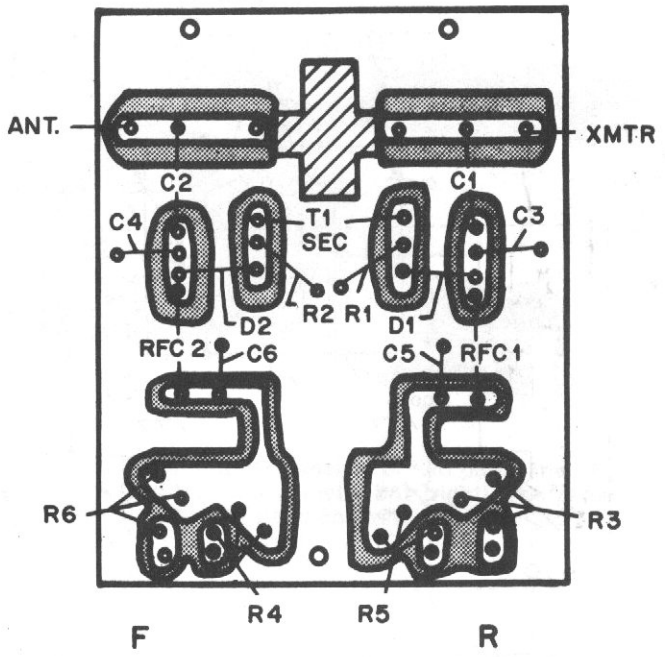

Fig 12—Etching pattern and parts layout for the RF wattmeter, as viewed from the foil side of the board. The etched-away portions of the foil are shown as darkened areas in this drawing. The area with diagonal lines is to be cut out for the mounting of T1.

is that of calibrating the power meter for a desired wattage range. The least involved method is to use a commercial wattmeter as a standard. If one is not available, the power output of the test transmitter can be computed by means of an RF ammeter in series with a 52-ohm dummy load, using the standard formula, $P = I^2R$. The calibration chart of Fig 10 is representative, but the actual calibration of a particular instrument will depend on the diodes used at D1 and D2. Frequently, individual scales are required for the two power ranges.

Connect a noninductive 52-ohm dummy load to J2. A Heath Cantenna or similar load will serve nicely for adjustment purposes. Place S2 in the FORWARD position, and set S1 for the 100-watt range. An RF ammeter or calibrated power meter should be connected between J2 and the dummy load during the tests, to provide power calibration points against which to plot the scale of M1. Apply transmitter output power to J1, gradually, until M1 begins to deflect upward. Increase the transmitter power and adjust R4 so that a full-scale meter reading occurs when 100 watts is indicated on the RF ammeter or other standard in use. Next, switch S2 to REFLECTED and turn the transmitter off. Temporarily short across R3, turn the transmitter on, and gradually increase power until a meter reading is noted. With an insulated screwdriver, adjust C2 for a null in the meter reading.

The next step is to reverse the coax-connections to J1 and J2. Place S2 in the REFLECTED position and apply transmitter power until the meter reads full scale at 100 watts output. In this mode the REFLECTED position actually reads forward power because the bridge is reversed. Calibrating resistance R3 is set to obtain 100 watts full scale during this adjustment. Now, switch S2 to FORWARD and temporarily place a short across R4. Adjust C1 for a null reading on M1. Repeat the foregoing steps until no further improvement can be obtained. It will not be necessary to repeat the nulling adjustments on the 1000-watt range, but R5 and R6 will have to be adjusted to provide a full-scale meter reading at 1000 watts. If insufficient meter deflection is available for nulling adjustments on the 100-watt range, it may be necessary to adjust C1 and C2 at some power level higher than 100 watts. If the capacitors tune through a null, but the meter will not drop all the way to zero, chances are that some RF is leaking into the bridge circuit through stray coupling. If this is the case, it may be necessary to experiment with the shielding of the through-line section of the RF head. If only a small residual reading is noted it will be of minor importance and can be ignored.

With the component values given in Fig 10, the meter readings track for both power ranges. That is, the 10-watt level on the 100-watt range and the 100-watt point on the 1000-watt range fall at the same place on the meter scale, and so on. This no doubt results from the fact that the diodes are conducting in the most linear portion of their curve. Ordinarily, this desirable condition does not exist, making it necessary to plot separate scales for the different power ranges.

Tests indicate that the SWR caused by insertion of the

power meter in the transmission line is negligible. It was checked at 28 MHz and no reflected power could be noted on a commercially built RF wattmeter. Similarly, the insertion loss was so low that it could not be measured with ordinary instruments.

Operation

It should be remembered that when the bridge is used in a mismatched feed line that has not been properly matched at the antenna, a reflected-power reading will result. The reflected power must be subtracted from the forward power to obtain the actual power output. If the instrument is calibrated for, say, a 52-ohm line, the calibration will not hold for other values of line Z_0.

If the instrument is to be used for determining SWR, the reflected-to-forward power ratio can easily be converted into the corresponding voltage ratio for use in Eq 2 given earlier. Since power is proportional to voltage squared, the normalized formula becomes

$$SWR = \frac{1 + \sqrt{k}}{1 - \sqrt{k}}$$

where k is the ratio of reflected power to forward power. The *power* curve of Fig 8 is based on the above relationship, and may be used in place of the equation to determine the SWR.

An Inexpensive VHF Directional Coupler

Precision in-line metering devices capable of reading forward and reflected power over a wide range of frequencies are very useful in amateur VHF and UHF work, but their rather high cost puts them out of the reach of many VHF enthusiasts. The device shown in Figs 14 through 16 is an inexpensive adaptation of their basic principles. It can be made for the cost of a meter, a few small parts, and bits of copper pipe and fittings that can be found in the plumbing stocks at many hardware stores.

Construction

The sampler consists of a short section of handmade coaxial line, in this instance, of 52-ohms impedance, with a reversible probe coupled to it. A small pickup loop built into the probe is terminated with a resistor at one end and a diode at the other. The resistor matches the impedance of the loop, not the impedance of the line section. Energy picked up by the loop is rectified by the diode, and the resultant current is fed to a meter equipped with a calibration control.

The principal metal parts of the device are a brass plumbing T, a pipe cap, short pieces of 3/4-inch-ID and

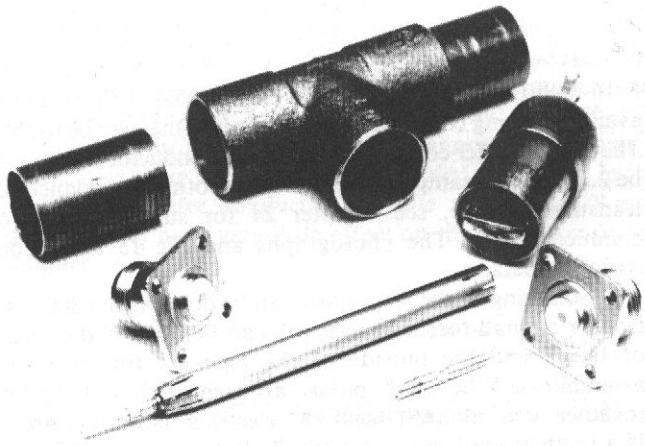

Fig 14—Major components of the line sampler. The brass T and two end sections are at the upper left in this picture. A completed probe assembly is at the right. The N connectors have their center pins removed. The pins are shown with one inserted in the left end of the inner conductor and the other lying in the right foreground.

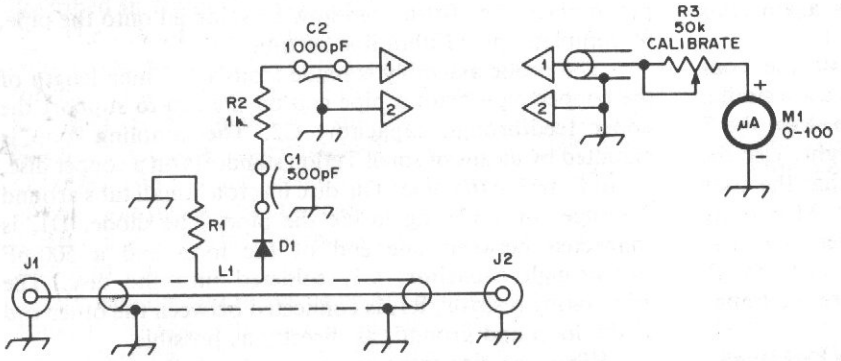

Fig 13—Circuit diagram for the line sampler.
C1—500-pF feedthrough capacitor, solder-in type.
C2—1000-pF feedthrough capacitor, threaded type.
D1—Germanium diode 1N34, 1N60, 1N270, 1N295, or similar.
J1, J2—Coaxial connector, type N (UG-58A).
L1—Pickup loop, copper strap 1 in. long × 3/16 in. wide. Bend into "C" shape with flat portion 5/8 in. long.
M1—0-100 μA meter.
R1—Composition resistor, 82 to 100 ohms. See text.
R3—50-kΩ composition control, linear taper.

CRYSTAL SETS 2: SOME PRACTICAL DESIGNS

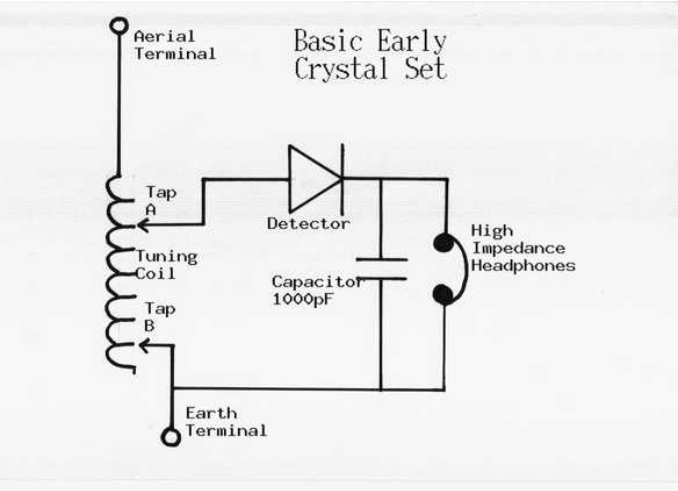
I hope that you attempt building one or two of these crystal set designs and I really do recommend that the components are carefully connected up using soldered joints onto a piece of tag-strip for reliability. However if you are new to constructing such electronic circuits then some simple solder-less techniques could be employed and these are suggested at the bottom of the page. Also see Crystal Sets Part 5 for more ideas on experimenting with crystal sets.

An early and very basic crystal set would have been nothing more than a coil of wire, perhaps 50 -100 turns, wound around a cardboard tube about 3 inches (7cm) in diameter, a detector (or cats whisker) and a pair of special High Impedance headphones (as discussed in part 1).

There would be a very large aerial strung up around the garden and the all important connection to earth.

The coil would have tapping points (connection points) at intervals of around 5 or 10 turns. See the circuit diagram on the right for details of who the set is wired together.

The tapping points on the coil allow the set to be tuned to different frequencies by adjusting the position of tap B. Tap B would be connected to the coil at differently positions by way of a crocodile clip. The fewer turns between the top (aerial end) of the coil and tap B, the shorter the wavelength received (ie the higher the frequency). Tap A would allow the detector to be connected at different positions to vary performance. There is an additional component drawn in the above diagram, the *capacitor* (value 1000pF), this is included in crystal sets that used the *High Impedance* magnetic headphones, and bypassed any remaining radio frequencies (RF) to earth.

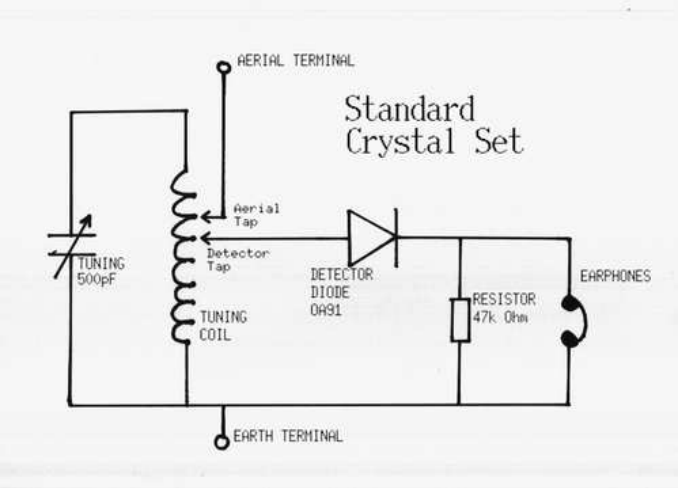


A very basic crystal set circuit.

I have not built the set described above as it is so basic. Such a crystal set above would probably have been adequate in 1920 - 1923 when there would have been only one local transmitter receivable.

When the BBC expanded transmissions and it became possible to hear more than a single station it would have became necessary to include a more convenient means of tuning the set.

This was achieved by including a Variable Tuning Capacitor, of about 500pF (0.0005uF) connected in parallel with the tuning



The Standard Crystal Set

coil forming a *tuned circuit*. The tuning capacitor would have a Bakelite knob on the spindle to aid tuning.

Because of the simplicity of crystal sets, it is often difficult to separate stations. When tuned into one station it is often possible to hear another close by station in the background, this is due to lack of *selectivity*. This can be reduced somewhat by adjusting the positions of the Aerial Tap and Detector Tap. Moving them closer to the bottom of the coil, the earthy end, reduces the load on the tuned circuit and this improves selectivity, however it does also reduce *sensitivity* which can make the station quieter. Headphones will often swamp a tuned circuit and reduce its selectivity (Q factor), so moving the tapping point lower down improves this situation. Every circumstance is bound to be different though so the best balance has to be found by experimentation. My crystal set has both the diode and the aerial connected to the same tapping point on the coil, about a quarter of the way down.

The modern 'standard crystal set' shown above uses a Crystal Earphone, since suitable high impedance magnetic headphones (of 2000 to 4000 ohms) are no longer widely available. When using a crystal earpiece the 1000pF capacitor shown in the first diagram can usually be omitted an in its place a 47k ohm resistor is connected, this ensures that the Crystal Earphone will work at its most efficient i.e. the sounds will be as loud as possible. The resistor allows DC current to flow through the circuit efficiently - this would otherwise be blocked when using a crystal earphone. In a modern crystal set the detector used is a *Diode.* Suitable diodes include OA80, OA81, OA90 OA91 and IN94 which are usually available from component stockists.

A Better Diode For Increased Efficiency

The OA47 will be of particular interest since it has the lowest forward bias voltage of any of these diodes which will make the crystal set somewhat more sensitive and therefore louder. The US equivalent of the British OA47 is the IN34.

On the right you will see my real working example of a crystal set

The large plastic knob on the front turns the variable tuning capacitor. This set receives the three UK national stations and also three local radio stations very well at my location.

There is a small 3.5mm jack socket mounted on the front of the plastic case (MB5 from Maplin Electronics) that the crystal earphone plugs into.

The coil can be seen inside the case, it is 70 turns of 30 gauge enamelled copper wire wound around the centre of a toilet roll and tapped every 10 turns, by scraping off the enamel insulation and making a small twist. The croc' clips can be seen clipped on to these twists to connect to the aerial and detector tap points.

A real working crystal set. Radio as if by magic with no battery or mains power.

THE MEDIUM WAVE COIL - MORE DETAILS

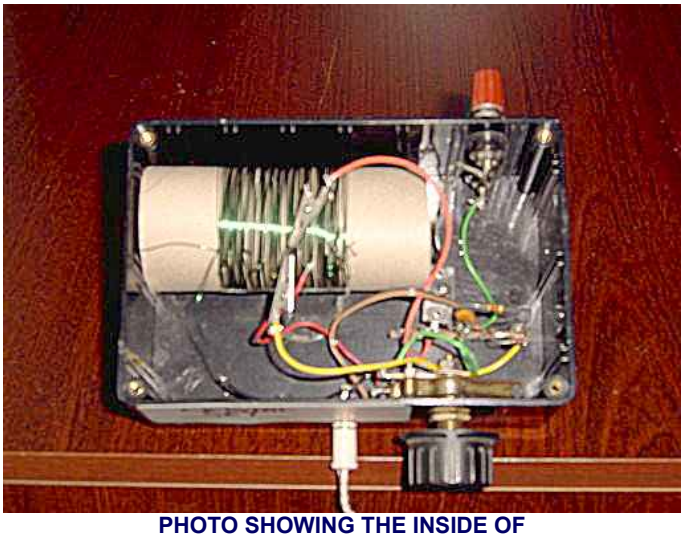


PHOTO SHOWING THE INSIDE OF THE COMPLETED CRYSTAL SET

Medium Wave Coil

The number of turns of wire required on the coil will vary depending on the size of the former (in this case the inside toilet roll) and the thickness of the wire. So to obtain the correct coverage of the medium wave band may need a little experimentation.

I usually find that between 50 to 90 turns is right and I generally use enamelled copper wire that is between 30 s.w.g. and 26 s.w.g (i.e. 0.315mm and 0.45mm diameter), so it's best to start with too many turns and then work down.

The more turns that you use the lower the frequency range will be, i.e. too many and the coverage of the top end of medium wave around 1500 - 1600 kHz will be lost, while too few and the coverage down to 500 kHz will be lost.

It is also important that the coil former is non conducting, i.e. not metallic. It could be wood or cardboard or a short piece of PVC piping and with a diameter of between 1½ and 4 inches (4 to 15 cm) are common sizes. You could try using a ferrite rod too, see below.

This particular set has a coil wound onto a toilet roll tube which consists of 70 turns of 30 s.w.g. (0.315mm dia) enamelled copper wire tapped at every 10 turns. It also has the additional small trimmer capacitor that helps match the aerial to the tuned circuit thereby improving selectivity, see below.

USING A FERRITE ROD AS THE COIL FORMER

The aerial coil could be wound onto a ferrite rod.

A piece of 10mm diameter ferrite rod of between 3 and 6 inches long (80 to 150mm) will be most suitable and will require between 50 and 90 turns of enamelled copper wire to provide coverage of the medium wave band: First make a paper tube that is held together with sticky tape that will easily slide up and down the ferrite rod. Then wind the coil over this with the windings neatly side by side. Make tapping points every 10 or 15 turns so that the aerial and diode tapping points can be adjusted.

Adjustments to the tuning range can be made by removing some wire from the coil so it is best to start off with too many turns and then work down. Fine adjustments can be made to the completed coil by sliding it up and down the ferrite rod.

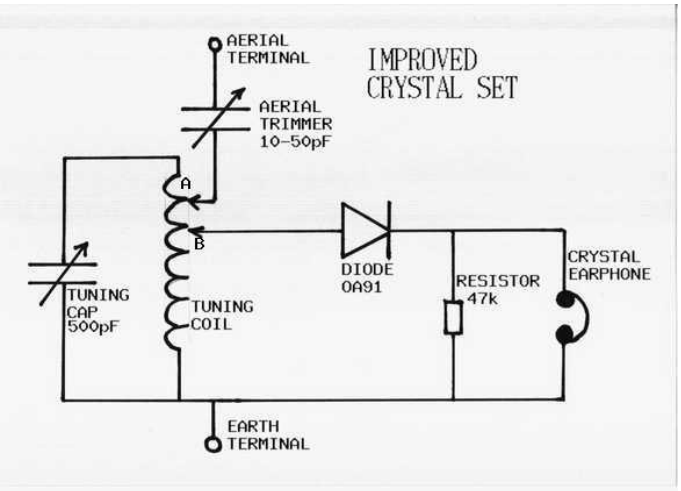
AN IMPROVEMENT TO THE DESIGN

The crystal set above also has one small, but significant, improvement over the standard crystal set and that is an Aerial Trimmer. A trimmer is a variable capacitor, very similar to the tuning capacitor, except smaller and adjusted with a screwdriver.

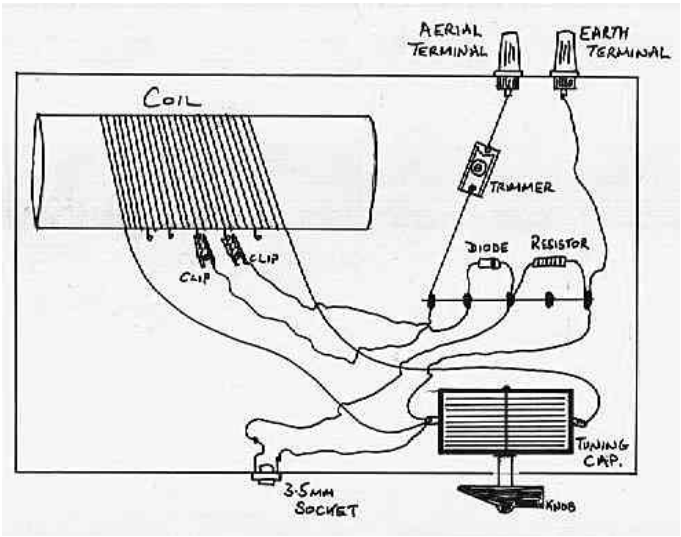
The value of the trimmer is usually around 10 - 50pF, but if a small tuning capacitor is available that will probably be just as effective. In the absence of such a variable capacitor, individual fixed ceramic capacitors of e.g. 10pF, 50pF and 100pF can be tried in this position to judge which gives the best results with the particular aerial being used.

The trimmer capacitor adjusts the coupling to the tuned circuit, reducing the load of the aerial on the tuned circuit will improve

the selectivity (Q), and it will be easier to separate stations. Again tapping points are used and I find this to be an excellent arrangement.



Improved Crystal Set design, with good selectivity



Layout Of The Crystal Set - Although this is soldered together an alternative to tagstrip would be a 5amp mains connector block so that components can be trapped in place with screws. See article below.

The picture on the right shows the general layout of the crystal set above. The coil is of approximately 70 turns is wound on the centre of a toilet roll, and has tapping points at 10 turn intervals.

The trimmer is soldered between the Aerial terminal and the piece of 5-way tag strip, and a wire goes from there to a croc' clip which is clipped onto a tap on the coil. The Diode is also soldered onto the tag strip, one end connected to a piece of wire going to a second croc' clip & connected to a tapping point on the coil, the other end of the diode is connected to the 3.5mm jack socket that the Crystal Earphone plugs into.

The 47k resistor is also connected to the earphone end of the diode and goes to earth, the earth terminal wire is soldered to the tag strip at this point too. The tuning capacitor has two terminals, one connected to each end of the coil, and one of them is also connected to earth as shown. [Where the wires cross over in the diagram, they do not touch and are not connected together].

LONG WAVES

In most areas around Europe and certainly around much of the UK you will be able to hear a Long Wave station. To receive Long Wave on a crystal set will require an aerial coil with a greater number of turns to increase its inductance.

As a good general guide a coil wound on a piece of 10mm diameter ferrite rod will require about 250 turns of enamelled copper wire: First make a paper tube that is held together with sticky tape that will slide up and down the ferrite rod. Then wind the 250 turn coil over this, the windings will have to be made over the top of each other. Make tapping points at, say, 50, 75 and 100 turns to tap the aerial and diode to.

As with the medium wave ferrite rod aerial, adjustments to the tuning range can be made by adding or removing some wire from the coil, and fine adjustments can be made to the completed coil by sliding it up and down the ferrite rod. The longer the ferrite rod the better and anything between 3 and 6 inches long (80 to 150mm) will be very good.

SHORT WAVES

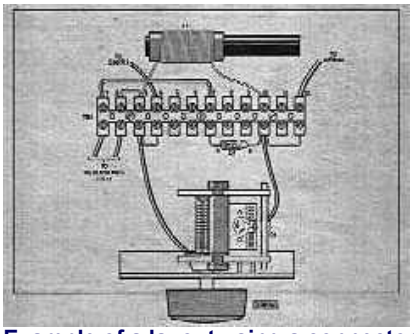
If you like experimenting, then reducing the number of turns on the coil to say 10 to 30 will allow reception of the higher frequencies, the Short Waves. I have found

that winding the coil around a 'ferrite rod' often works even better with short wave reception.

Obtain a ferrite rod about 7 to 15 cm long and about 1cm in diameter. Make a couple of small tubes of card, about 4cm long, that will fit tightly over the rod.

On one tube wind two coils using 0.5mm diameter enamelled copper wire - one coil of about 30 turns and a second one of 2 or 3 turns wound over the top of the first. Secure the windings in place with Sellotape.

On the other card tube wind a similar coil, but use about 15 turns for the first coil and for the second coil wind about 3 to 4 turns over the top, and secure with Sellotape tape.



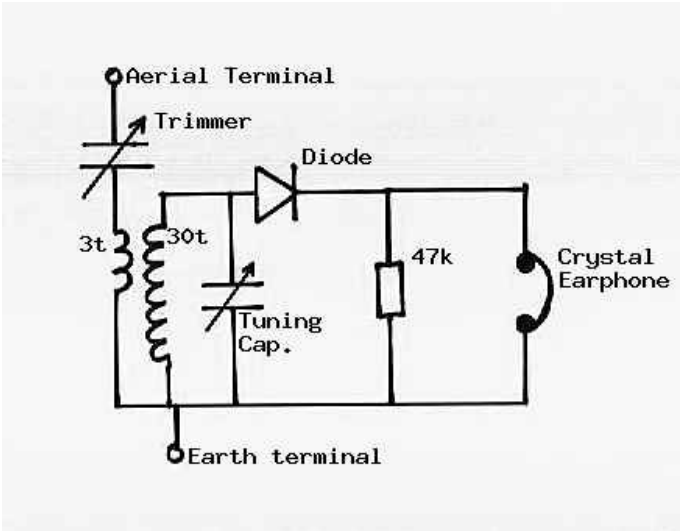
Example of a layout using a connector block to wire up a crystal set

These coils will provide coverage of short wave in two bands using the first coil for the longer wavelengths, typically 60 to 31 metre bands and the second coil for the shorter wavelengths typically 25 to 19 metre band. Wire up the circuit as shown in the circuit diagram below.

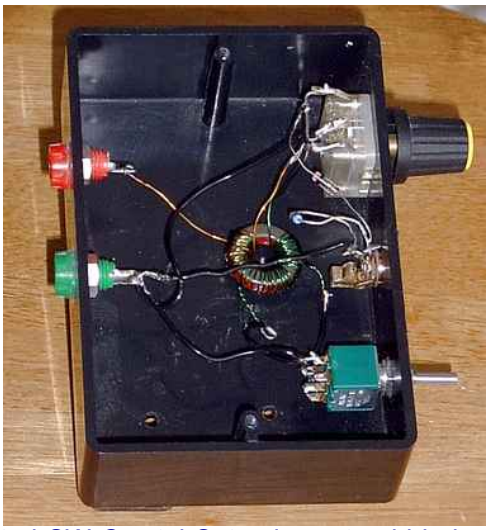
USING A TOROID INDUCTOR FOR SHORT WAVES

Even better selectivity performance can be achieved by winding the inductors (coils) on a ferrite toroids (T50-2 yellow, or green will do). The aerial trimmer need not be used if selectivity and sensitivity is found to be adequate. It's all about experimenting, and I find it best to use a trimmer or small coupling capacitor to obtain the best selectivity.

Up to 30 turns of 0.5mm enamelled copper wire can be used for the longer short waves below 10 MHz, while a winding of around 15 turns will provide coverage of the shorter short waves above 10MHz.



The circuit diagram of the Short Wave Crystal Set



A completed SW Crystal Set using a toroid inductor. Note: the main winding has a tap to allow the switch to short part of the winding and thereby give two ranges.

AUSTRALIAN DESIGN

Moving back to the Medium Waves, here is a circuit for a very interesting Australian design that promises extremely good station separation (selectivity), and having built it I can vouch for that claim, it's really excellent.

I receive three national stations and three local stations at my location with excellent clarity using a modest antenna and standard crystal earphone.

The coil is different to the other crystal sets described above, it is

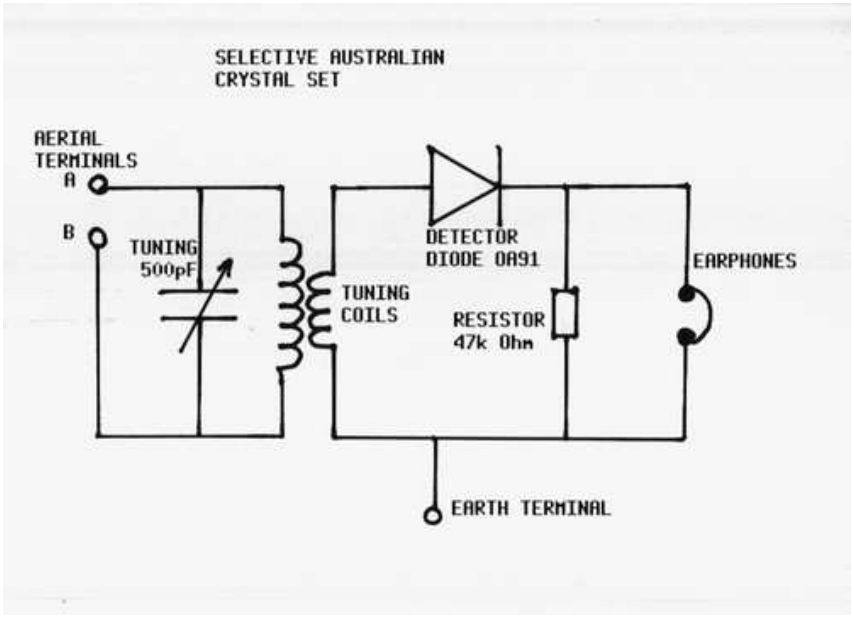
The front panel of the Australian Crystal Set

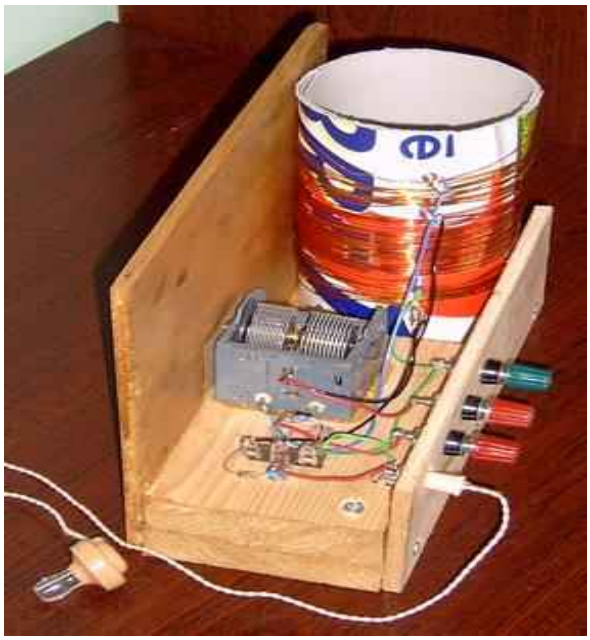
much bigger at 3¼ inches (8cm) diameter and 5inches (12cm) long. I made my coil former out of the cardboard from a breakfast cereal box - just like Blue Peter!

The design is often referred to as The Mystery Crystal Set, by Proton.

Two distinct coils are wound on it, the first one consists of about 50 turns of 24 s.w.g (approx) enamelled copper wire. The second coil is 25 turns, very close wound right over the top of the first coil using 30 s.w.g. (approx) wire, try to get this second coil wound in between the windings of the first, for better inductive coupling.

Then carefully wire up the set according to the diagram. Notice that the tuned circuit is not connected to earth and has no *direct* connection to the detector circuit. The detector circuit *is* connected to earth however. The two aerial terminals offer alternative selectivity performance, terminal A gives very good selectivity while B is very wide. I never bother with B.





Make the coil carefully and wire up this crystal set according to the circuit diagram opposite and you will be rewarded with a really high performance crystal set of a type that was used in the very early days of broadcasting in 1930's in Australia.

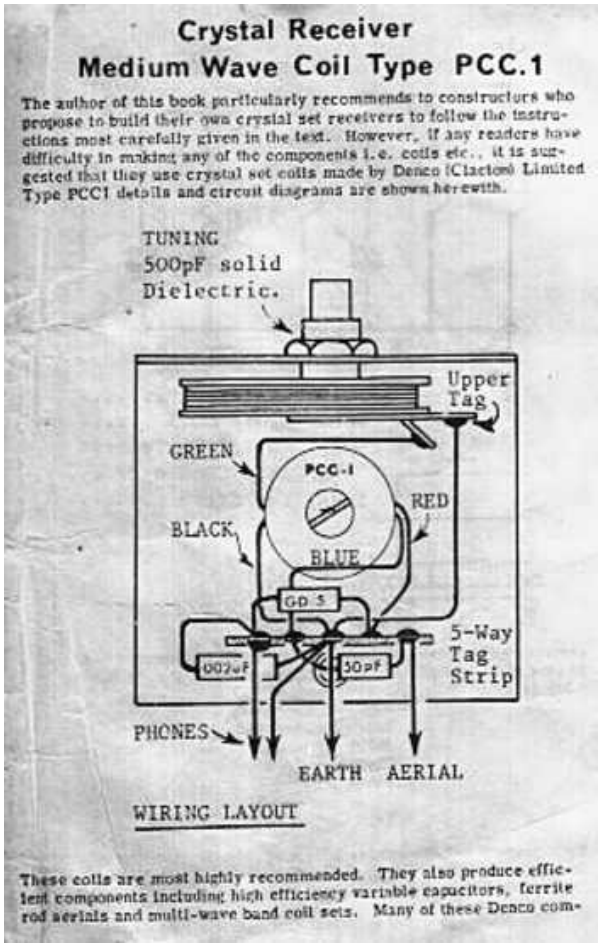
This is probably my favourite crystal set!

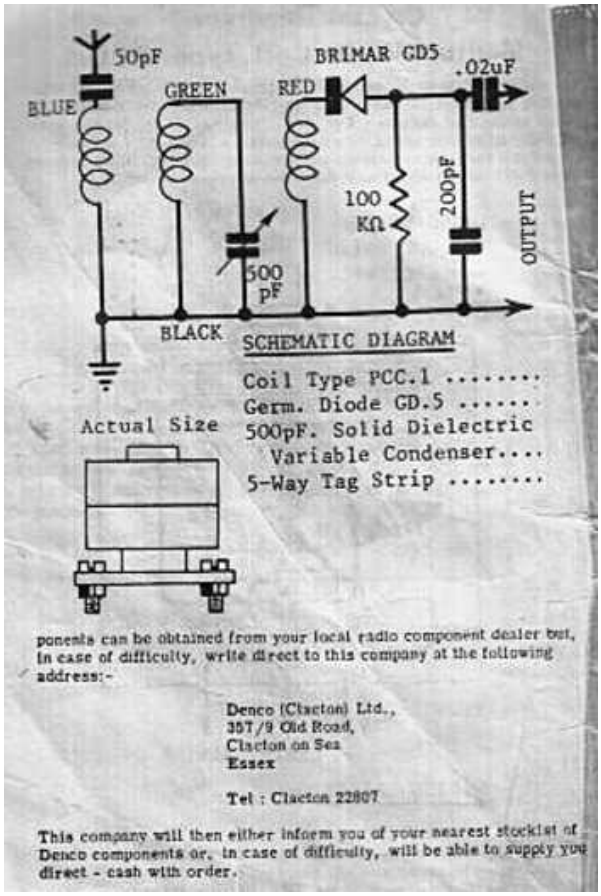
THE DENCO PCC1 COIL

The PPC1 coil was a commercially manufactured by Denco Clacton Ltd and was popular among hobbyists not keen on going to the bother of winding their own fiddly little coils. As a child I wanted try one of these coils and sent away for one by mail order. It arrived a few days later in a little cloth bag, like a miniature pump bag, with protective wrapping inside.

The coil windings are entirely enclosed in what I can only describe as a cylindrical ferrite 'shell', the four very thin connecting wires exiting, two either side, from small apertures in the 'shell'. The performance of the circuit shown below I seem to remember was quite pleasing. Unfortunately I cannot find the set or the PPC1 coil at the moment, but here is

a reproduction of the circuit diagram and data:



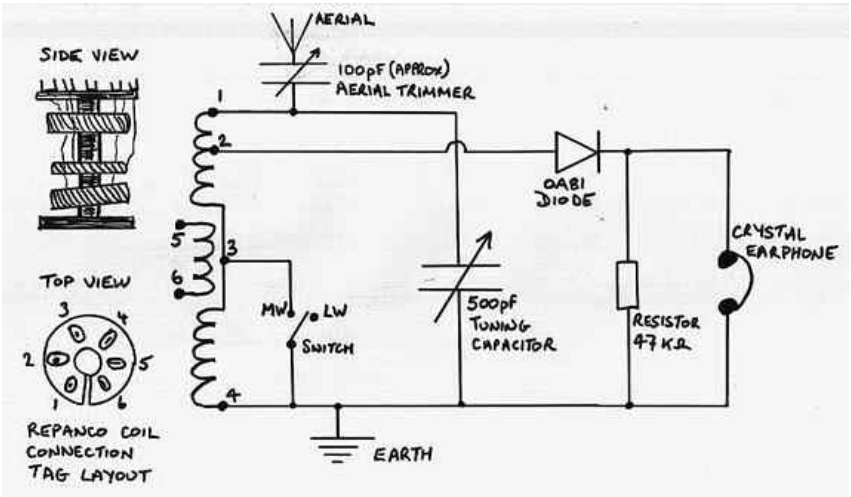


THE REPANCO DRR2 COIL

I recently rediscovered an old Repanco DRR2 Longwave / Mediumwave coil that must have been kicking around in my junk box since the 1970's.

The DRR2 coil was made by Repanco in Coventry. It came with a page of suggested circuit diagrams which I thought had been lost to the mists of time, but it recently came to light again, so I have now copied it below.

Once again I included an aerial trimmer which can be adjusted to improve selectivity.



The circuit diagram of the crystal set using the Repanco DRR2 coil

Repanco Ltd was formed by two ex-army signals engineers and from the earliest days of radio supplied crystal set kits and coils to radio construction enthusiasts.

The Repanco DRR2 coil was for medium wave and long wave intended for use in when building simple crystal set and valve radio

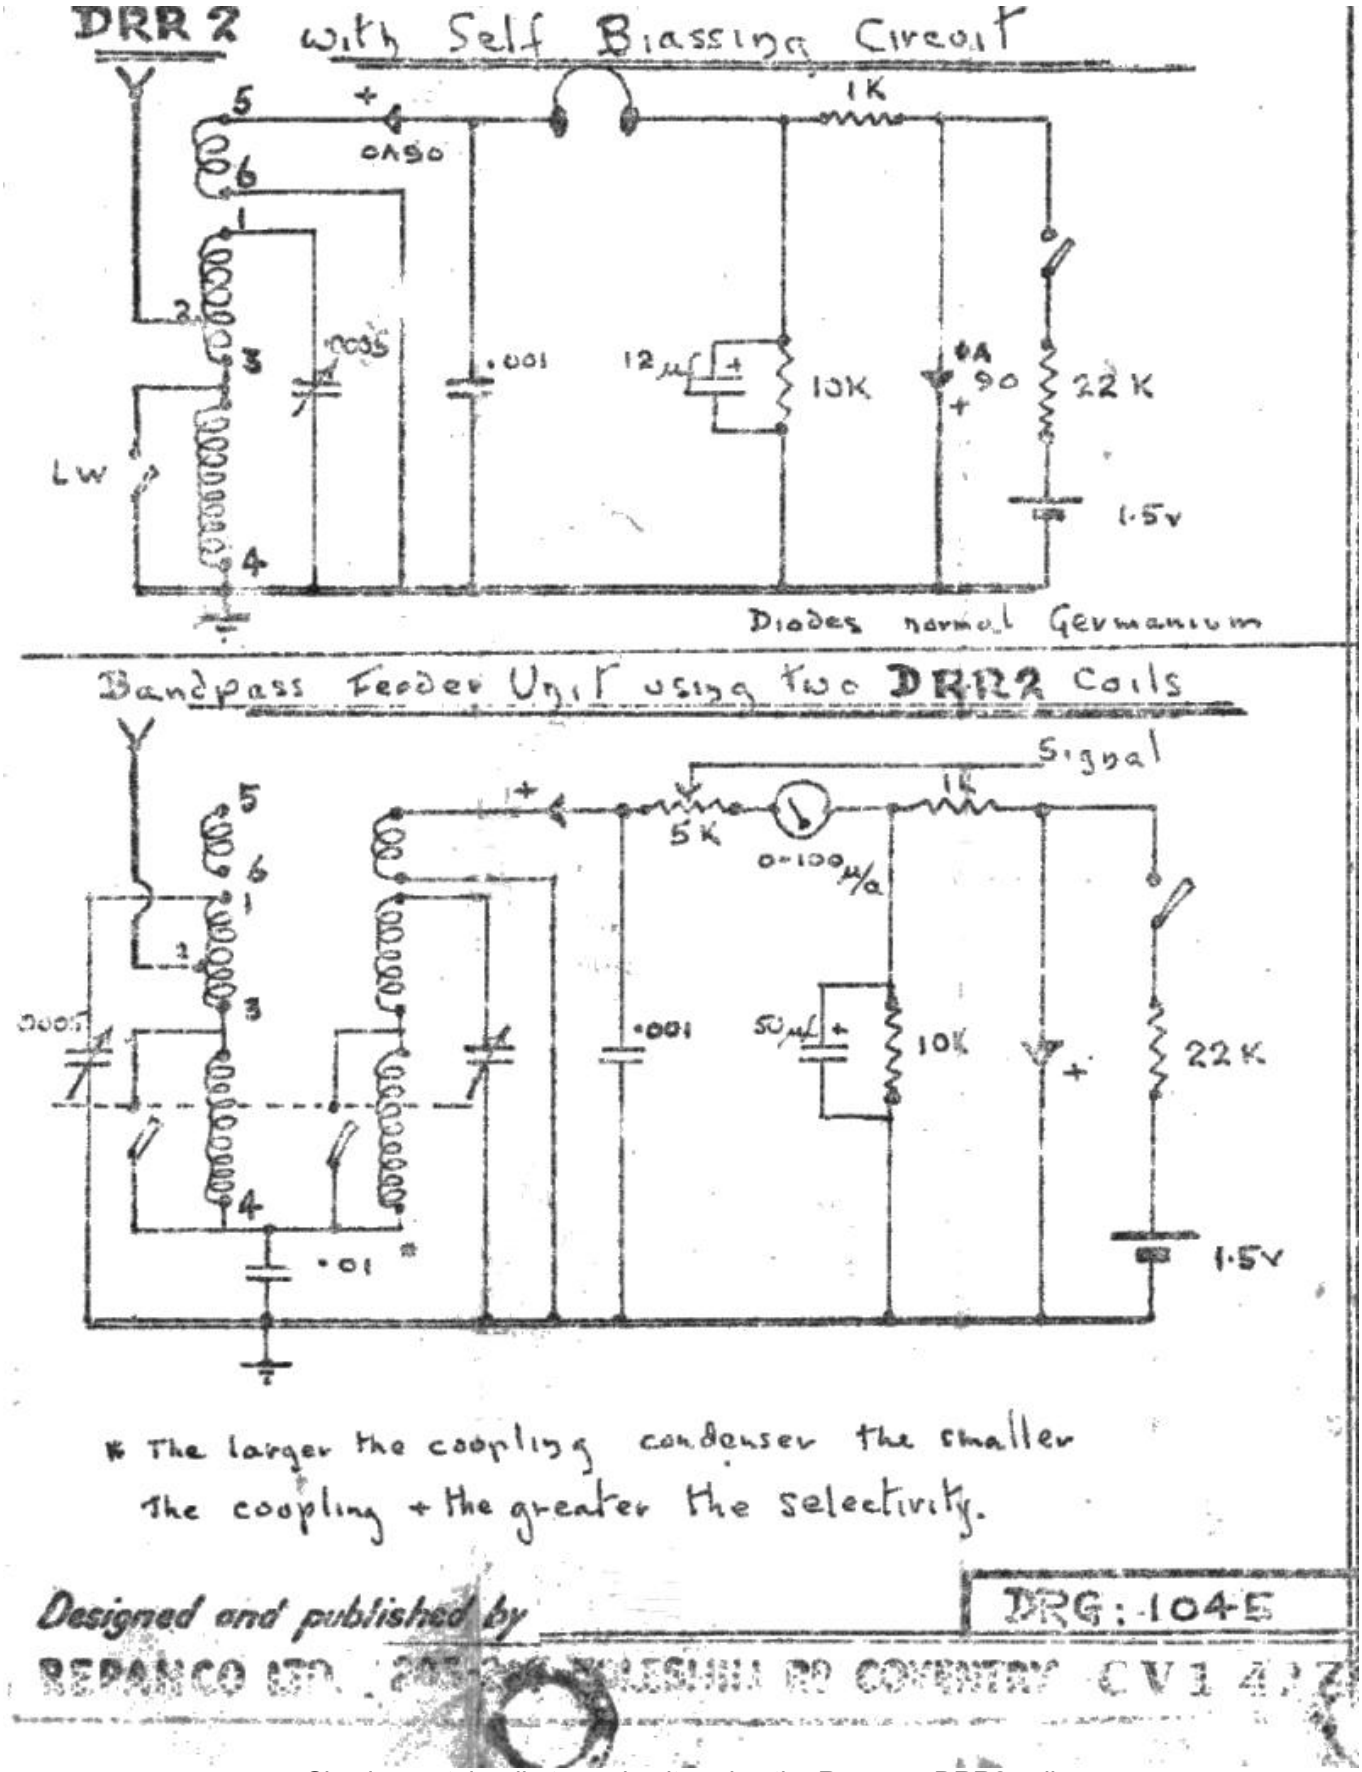
A 'lash-up' of the Repanco crystal set

circuits.

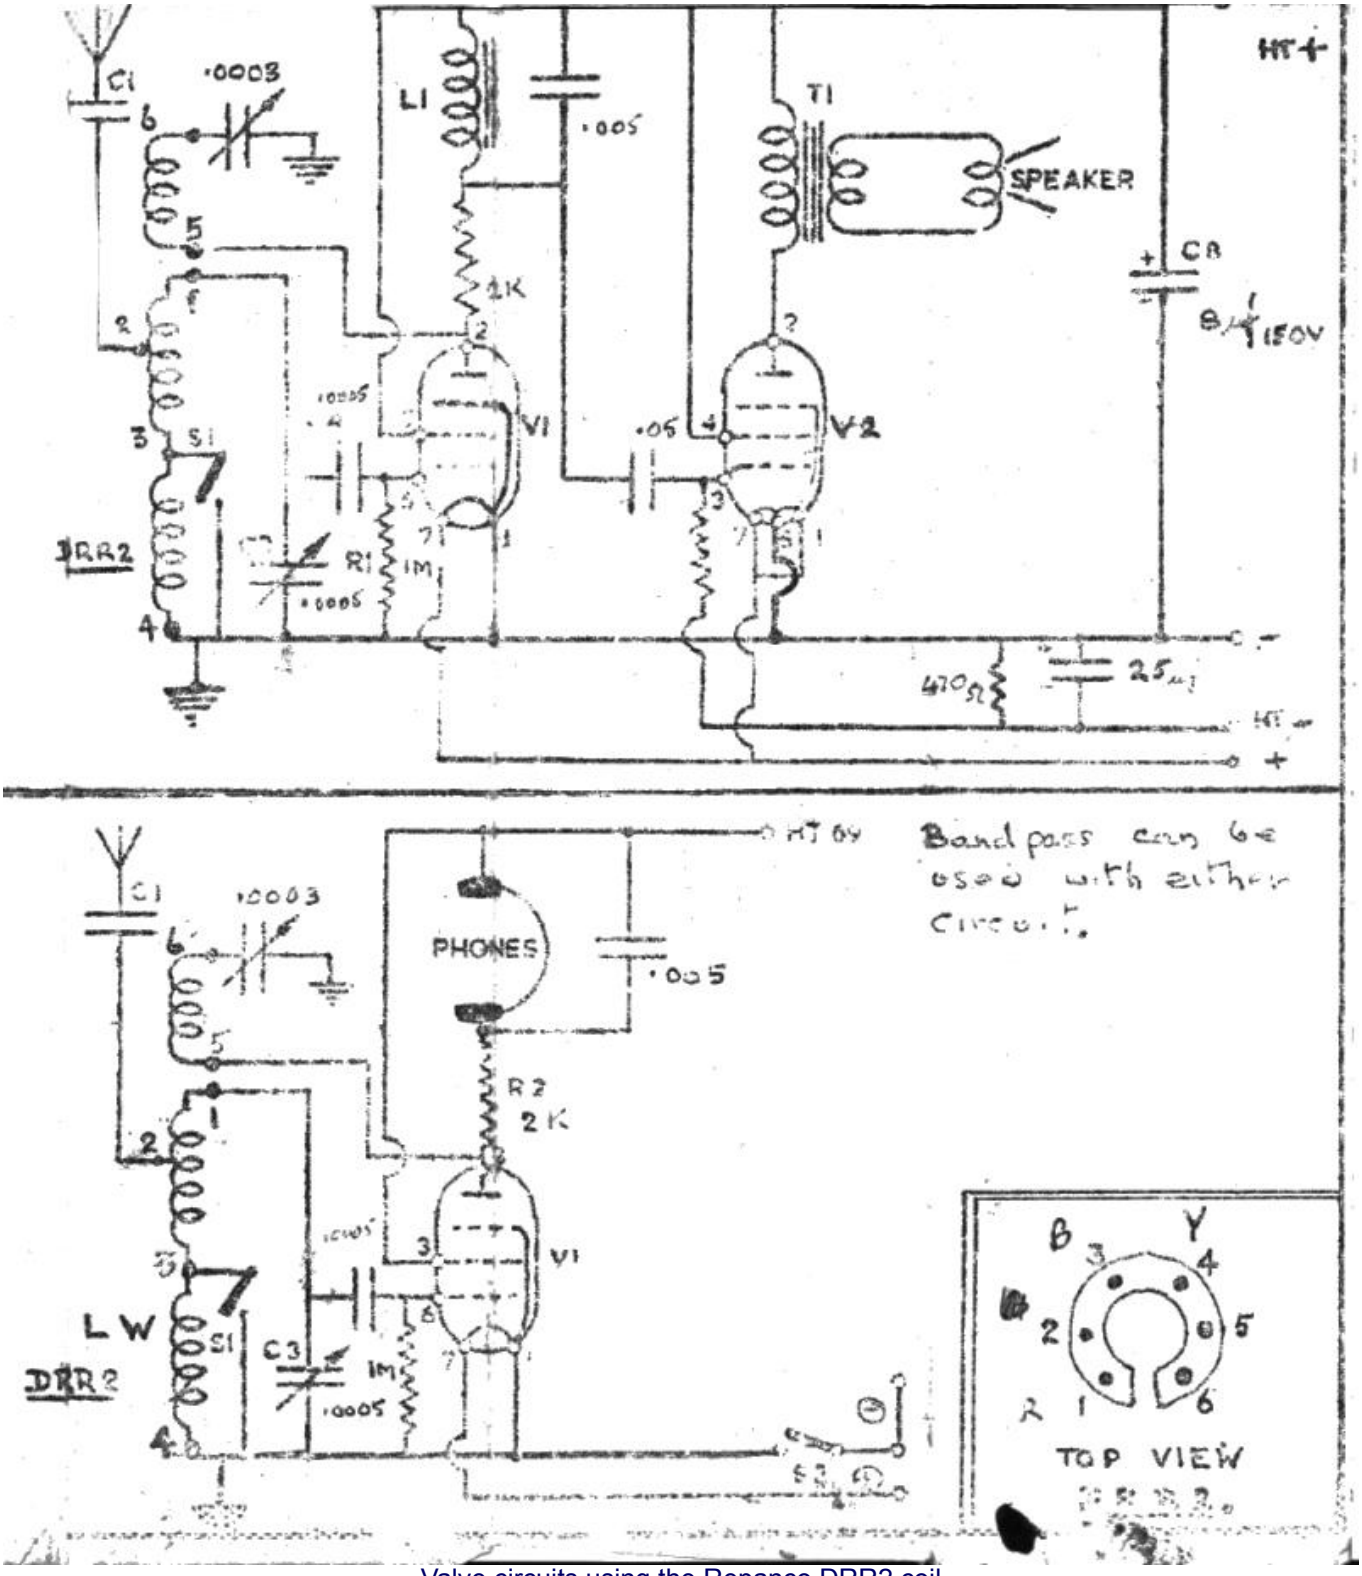
It consists of three coils; a Medium Wave coil at the top that includes a tapping point (for the aerial); a coupling coil or tickler in the middle; a lower coil which can be connected in series with to top coil to provide Long Wave reception.

I have built a quick crystal set with the coil and it provides good reception with excellent selectivity, so it must have a very good Q factor.

The Repanco DDR2 coil was provided with a simple Foolscap size information sheet that showed four different radio circuits. Sadly the sheet does not give a huge amount of information and my copy is now rather tatty and faded - it is copied below:



Simple crystal radio type circuits using the Repanco DRR2 coil



Valve circuits using the Repanco DRR2 coil

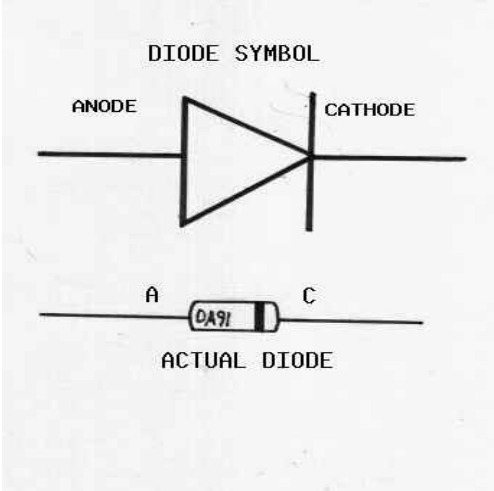
Repanco Ltd no longer produces radio coils and crystal set kits for the radio construction enthusiast, as it did in the early days of radio. In 1986 it was renamed Repanco Bartlett Ltd when it merged with Bartlett Electronics. The company moved from the Foleshill Road to Unit 24, Albion Industrial Estate, Endemere Road, Coventry CV6 5NT and now specialises in transformers and wound components and can design and manufacture to commercial customer requirements, their website is: http://www.repancobartlett.co.uk/

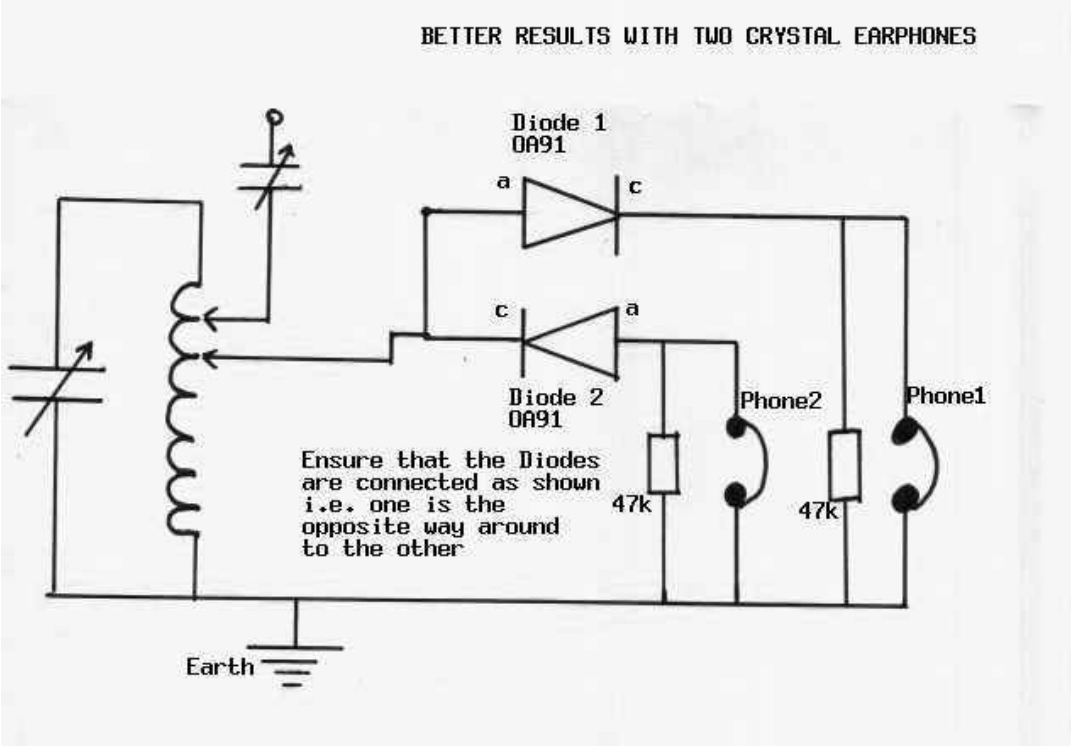
CRYSTAL EARPHONES

Here is a good idea and well worth trying, to maximise the use of sound output from your crystal set why not use dual crystal earphones? Having an earphone in each ear helps to block out extraneous noises helping the listener to better concentrate on any weaker stations received.

Using the circuit below, one earphone makes use of one half cycle of the radio wave while the second earphone uses the other half cycle of the wave that would have previously gone to waste when using just one diode. Ensure that the diodes are connected up according to the diagram i.e. one diode is connected the opposite way round to the other.

Also try to make sure that the diodes and crystal earphones are similar to obtain the best results. (You could simply connect two crystal earphones to the same terminals of the single diode, but this would not be as efficient and the sounds would be much quieter.)





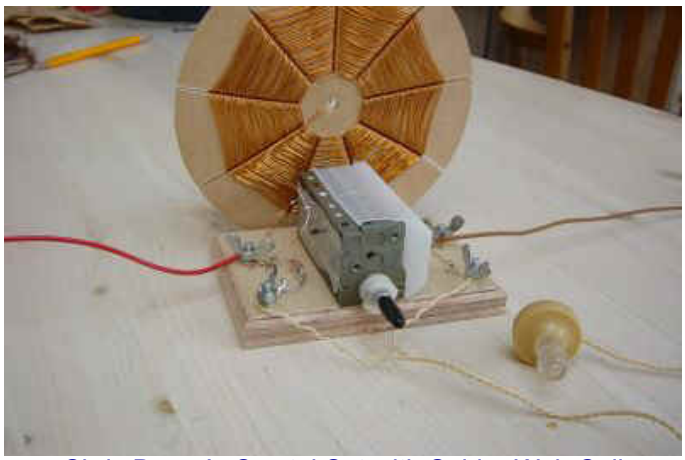
A note about Crystal Earphones: It will be worthwhile buying several different ones from different sources as performance varies between manufacturers quite markedly. I have found the ones marked 'Japan' on the back are the most sensitive and therefore loudest, whereas ones marked 'Receiver' 'Taiwan' are often a little less sensitive and therefore quieter and sometimes more 'tinny' sounding.

As mentioned previously it has been noted that the OA47 diode will be of particular interest since it has the lowest forward bias voltage of any of the common diodes available. This will make the crystal set somewhat more sensitive and therefore louder. The US equivalent of the British OA47 is the IN34.

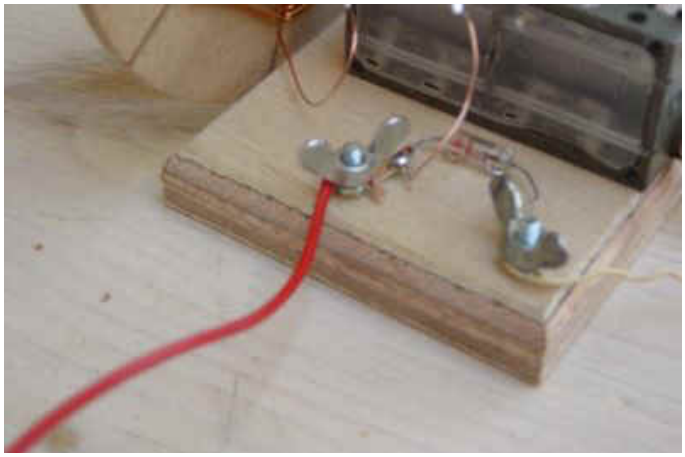
SPIDERS WEB' COIL

Here is an interesting concept sent in by Chris Dorna of the Vught North Scouts in the Netherlands. It is a crystal set made out of a coil wound in the form of a spiders web:

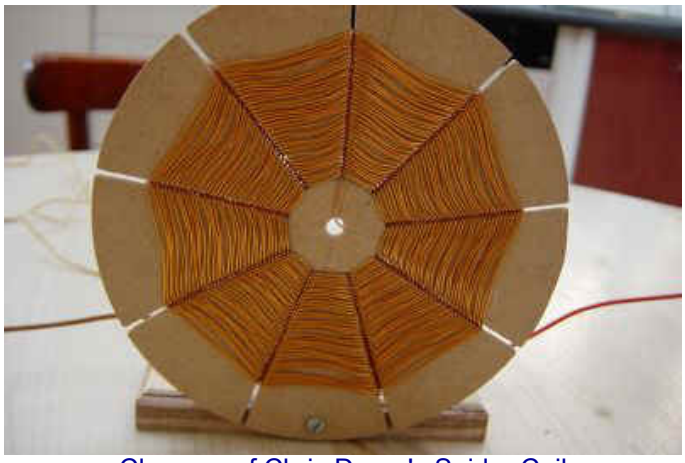
See more HERE.



Chris Dorna's Crystal Set with Spider Web Coil



Detail of the germanium diode



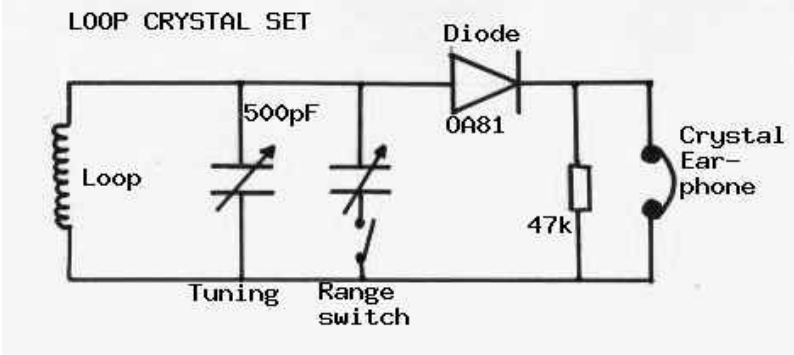
Close up of Chris Dorna's Spider Coil

LOOP THE LOOP!

A crystal set can also be made that does not need a large long wire aerial. If you have ever made a loop aerial for medium wave or long wave DX-ing, then it is a simple matter to add a diode, resistor and a socket to connect a crystal earphone that will allow reception of nearby stations.

See my section on Loop Aerials and ATU's for more constructional details.

A portable loop aerial, that incorporates a crystal set



The circuit diagram of the Loop Crystal Set. The loop is 10 turns of 7/0.2mm 'hook-up' wire wound on a 40cm (17") former made of attractive plastic edging strip available from many DIY stores. The loop is very directional in its pick up pattern, which can help eliminate interference from some stations by rotating the loop. The switch and additional capacitor allow tuning of the lower medium wave band from about 650 to 520 kHz. Having a loop with 50 to 60 turns of wire will tune into the Long Wave band.

DIODES - For Crystal Set Use - some notes by Felix Scerri

Germanium diodes for crystal set use.

Although I'm a fan of these new silicon schottky BAT 46 diodes, good germanium diodes still have a lot to offer, especially in terms of 'weak signal' sensitivity. Last night I did an experiment.

I sorted through quite a few of my hundreds of acquired random germanium diodes looking for particularly 'sensitive' ones. I tested this by tuning in a weak AM station and comparing the detected DC output level and also the apparent 'loudness' of the audio signal.

Even amongst germanium diodes of the same type, there was enormous variation all the way from excellent to poor! For very weak signals, germanium diodes 'detect' in the 'square law' region below the diode conduction 'knee', in a rather different part of the curve than with much stronger signals (way beyond the diode knee).

When testing germanium diodes for weak signal sensitivity, the inherent capacitance of the diodes is also a factor, and the 'tuning' may change somewhat and will need to be readjusted with every diode tested!

In the end, out of a large number of germanium diodes tested, I found three or four germanium diodes with excellent weak signal sensitivity and the rest were poor. One other interesting thing, good germanium diodes 'sound' different, rather more 'rounded and smoother' than the schottky's which tend to sound mercilessly clean, almost clinical. I also found almost no variation in weak signal sensitivity with my BAT 46 schottky diodes. Take your pick!

Regards, Felix Scerri VK4FUQ 14/03/2012

SOLDERLESS CONSTRUCTION IDEAS

For a novice the use of a soldering iron may seem a bit daunting at first and while the most reliable results will be obtained with a good soldered joint using a tag strip as shown below, the circuits can still be made without the use of a soldering iron.

5 WAY TAG STRIP

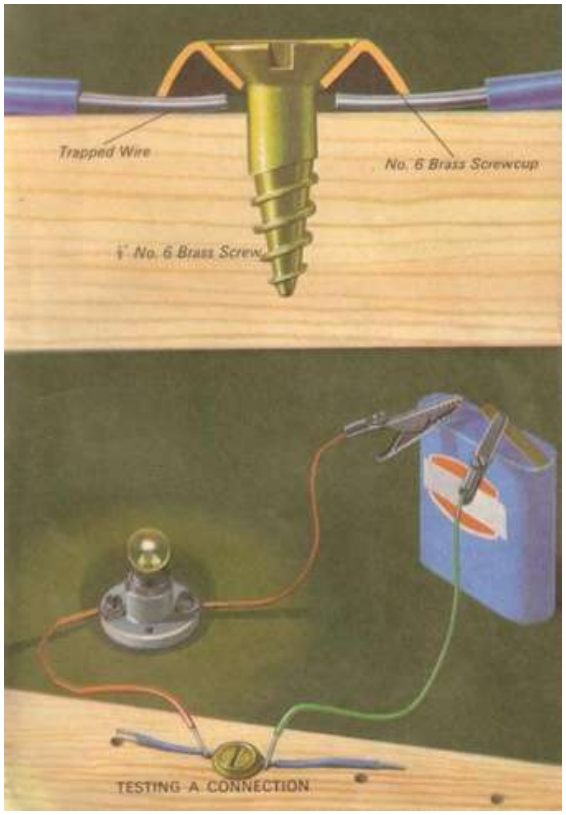
36 WAY TAG STRIP - TWO ROWS

The very simplest circuits could be wired together ,with a little ingenuity, with the component wires being held together in the grip of solderless crocodile clips, whereby the connecting hook-up wire is fixed to the croc' clip by a screw rather than solder.

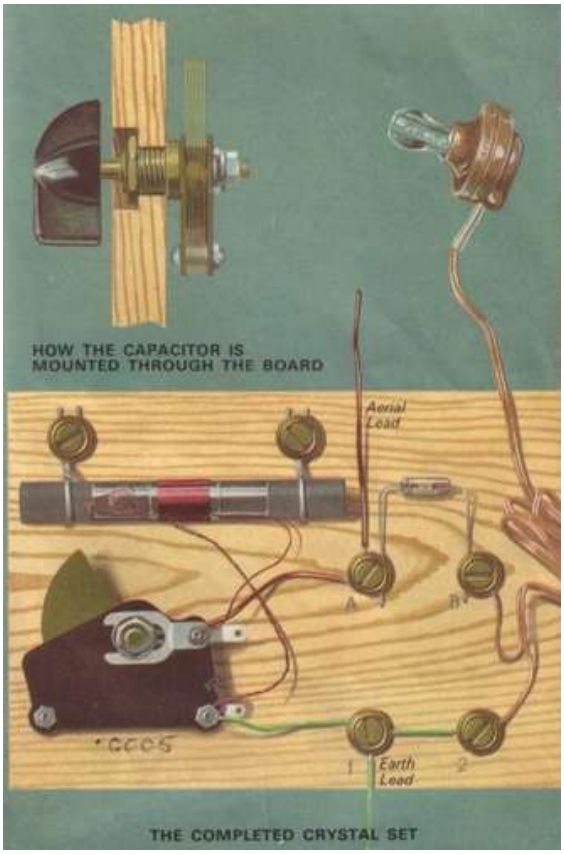
For more the slightly more complex circuits a plastic Terminal Block (sometimes referred to as a choc' or chocolate block) can be utilised very effectively indeed. These are used in mains wiring and are available in various sizes; 2 Amp, 5 Amp, 15 Amp and 30 Amp. The 5 and 15 Amp Terminal Blocks I have found to be the most suitable. The various component wires can be trapped securely with the screw at each junction point. This method also makes it easy to change the components around when experiment with different circuits. See The EXPERMENTAL CRYSTAL SET for more details in Part 5.

'CHOCOLATE' TERMINAL BLOCK

The Ladybird book called 'Making A Transistor Radio' (also shown on the TRF Radio pages) detailed a very novel approach using brass screws with screw-cups to trap the component wires at each junction point:



THE BRASS SCREW AND SCREW-CUP METHOD OF CONSTRUCTION



A VERY SIMPLE CRYSTAL SET USING THE BRASS SCREW AND CUP METHOD

Crystal Sets Part Part 3 >

No AM radio stations or transmitters in your locality or country?

Has your local medium wave broadcast station closed or been moved to VHF/FM or Digital? Don't worry. You can still build and experiment with crystal sets and TRF radios by also buying or even building a simple low power AM transmitter. So, not only can you use your crystal sets but you can also run your own radio station that can be heard in and around your home - playing the music or programmes that you want to hear!

SSTRAN AMT3000: Superb high fidelity medium wave AM transmitter kits from SSTRAN. Versions available for 10kHz spacing in the Americas (AMT3000 or AMT3000-SM) and 9kHz spacing in Europe and other areas (AMT3000-9 and AMT3000-9SM). Superb audio quality and a great and well designed little kit to build:

Building an AM radio

Objectives

By the end of this lab, the students should be able to:

- describe the function of the variable resistor, variable capacitor in the radio circuit
- describe how variable capacitors are connected in circuits
- describe how variable resistors are connected in circuits
- describe the "hidden workings" of a electronics prototyping board
- construct a AM radio (or any circuit) using a project board, components, jumper wires and a diagram

Introduction

Amplitude Modulated (AM) radio signals carry an audio signal (electrical information that can be converted to sound). The audio information is encoded on the radio wave by changing the amplitude of a high frequency radio wave. The base frequency of the electromagnetic radio wave (called the carrier wave) is much higher than the frequency of the audio information it carries (550kHz to 1600kHz versus 20Hz to 20kHz). The diagram at right shows how the encoding works. The amplitude of the carrier wave is not constant. The fast variation is the carrier wave. The relatively slow variations in the amplitude create an envelope that shows the frequencies in the audio signal. The diagram is somewhat distorted to show the principle. The amplitude of a typical radio signal varies much more slowly than the picture suggests. (How many periods of a 600kHz carrier would have to be shown in order to show half of a period of a 100 Hz sound?)

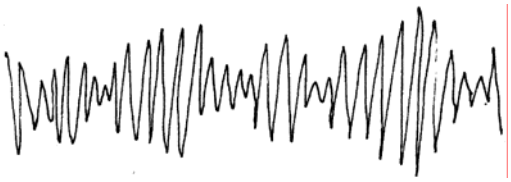

Figure 1: Amplitude modulated carrier signal

An extremely basic AM radio, consisting of a detector (a diode in the circuit at the right) and an antenna, is shown at right. The diode only allows current to flow in the direction indicated by its symbol. This circuit detects AM signals and converts them to audio signals.

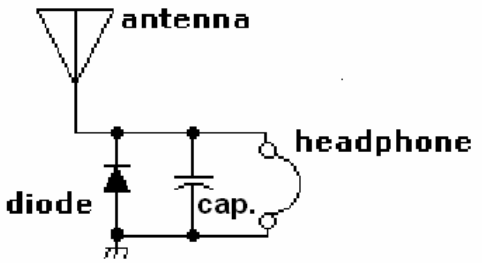

Figure 2: Simple AM detector circuit

The second circuit at the right is a (slightly) more sophisticated version. The design includes a tuning section. By setting the resonant frequency of the circuit to the frequency of the desired carrier wave, the user selects one carrier frequency for conversion.

The radio you will build (see the diagrams on the last page of the handout) includes an AM detector (a transistor in this case), a low pass filter (to remove the carrier wave from the audio signal) and an amplifier.

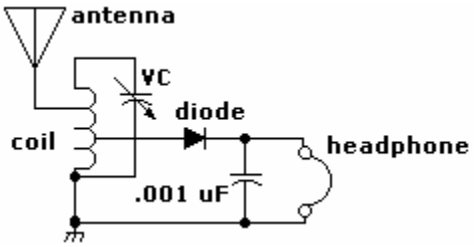

Figure 3: AM detector circuit with tuner block

Web Resources

The web has some good resources on AM radios. Googling "crystal radio" yields quite a bit of info on how to build a radio. One such site is http://sci-toys.com/scitoys/scitoys/radio/radio.html. The web also has some good explanations of how the AM detector works. Google "AM detector" or "envelope detector". One such resource is http://www.st-andrews.ac.uk/~www_pa/Scots_Guide/RadCom/part9/page2.html.

Building an AM radio

Instructions

1. Some of the AM radio is already made. A battery holder, coil, variable capacitor, potentiometer (a.k.a. variable resistor), project board and earphone jack have been mounted to a small piece of plywood.
    - Identify which component is which.
    - Use a multimeter to figure out how the potentiometer works. (Hint: Use the ohm-meter setting on the multimeter).
2. Prototype board is used for making and testing temporary circuits. Prototype boards have internal connections. The internal connections allow you to build a circuit with relatively few wires needed and to avoid soldering). Obtain an un-mounted project board. Inspect it. Figure out the pattern of internal connections. You can do this by looking at the back of an un-mounted project board or by using an ohm-meter.
    - Which holes will be at the same potential (provided small currents are flowing)?
    - Which holes can be held at different potentials? In other words, which sets of holes are electrically isolated from each other?
3. Obtain a kit of components for your radio. Inspect them.
    - Identify the different kinds of components: resistors, capacitors, transistors, and integrated chip.
    - ***Hooking up asymmetric components incorrectly will lead to unintended operation*** (more often than not unintended operation means ***self-destruction***). Identify all non-symmetric components. Note: Some "two-legged" components, including many capacitors, are asymmetric.
4. Use the diagrams on the next page to construct the circuit. You may note slight discrepancies between the parts in your kit and the parts provided. In particular, the resistance values called for might not match the contents of your kit. In general, you can use resistance values that are within a factor of two or so and still get the circuit to work. ***Pay attention to the proper connection of asymmetric components*** (including capacitors)! ***Leave the battery out*** until you have visually double-checked the circuit against the diagram.
5. Put in the battery and test the radio. In order to get a signal, you may need to …
    - tune the radio. (Which circuit element does this?)
    - turn up the volume on the earphone (Which circuit element does this?)
    - rotate the entire radio. (Why might the orientation matter? Which element needs to be aligned? What does it need to be aligned with? Why?

CONSTRUCTION OF RADIO RECEIVING APPARATUS

By The Laboratory Staff

Editor's Note: The apparatus described in this article has been constructed and tested in the Everyday Mechanics Experimental Station. The models may be seen at the Publication Offices of the magazine.

IN presenting the two designs embodied in this article, we do not wish to pose as originators of new types of apparatus, and neither do we wish to give the impression that the apparatus we have constructed is superior to anything on the market. The loading inductance presents no startling improvements in design or construction and the receiving transformer is just a good, substantial piece of apparatus that an advanced amateur need not be ashamed to construct and operate.

What we have endeavored to do, however, is this: We have tried to eliminate the defects, principally mechanical, that seem inherent in amateur apparatus; we have attempted to produce a design pleasing to the eye, convenient and smooth in operation, simple and inexpensive in construction, and of correct proportions and specifications from the radio standpoint.

The old "loose coupler" type of receiving transformer has long been a favorite for the very simple reason that it gives such universal satisfaction. The writer well remembers the experience of one of the best known manufacturers of amateur apparatus of the better grade. For years this concern had manufactured and sold great quantities of a certain number—a comparatively simple receiving transformer with sliding contacts and telescoping primary and secondary. True, the workmanship was excellent—as it was on every number turned out by the company—but there was nothing startling about that "loose coupler" to give it such a reign of popularity. However, when the manufacturer tried to substitute a perfect wonder of a tuner, with variometer coupling and a myriad of instrument-switch contacts, offering the new and improved device at the same figure as that asked for the plebeian coupler, the trade appeared to receive the newcomer with indifference and doubt. After several years of pushing and advertising, the little tuner had to be discontinued, relinquishing the field to a revival of the old-fashioned coupler. It is an actual fact that the demand for the old favorite was greater, probably just because of its simple goodness, than that for the improved instrument which was really a much better buy, value considered, than its successful predecessor.

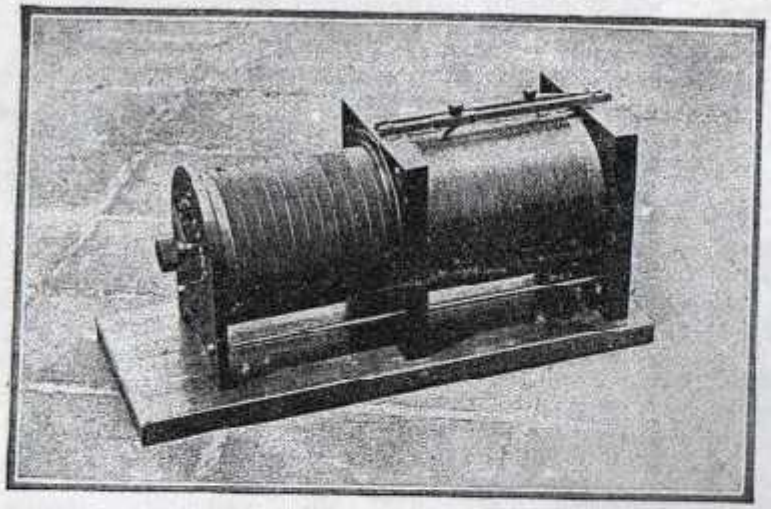

Fig. 1. Receiving transformer completed

Perhaps the reader will wonder at this digression. It is given merely to justify the publication of the design of a type that has been described many, many times in contemporary magazines. If our readers could but see our models, turn their contact knobs, and listen in to the gratifying results obtained, this justification would be unnecessary. Whatever adverse criticism this article may bring forth, the fact remains that there are probably more of these simple receiving transformers in use, and in *successful* use, too, than there are of any or all other types.

The Receiving Transformer

This transformer has instrument switch adjustment for secondary inductance and sliding contact adjustment for the primary. The construction is such that no metal (supporting rods) is used inside either primary or secondary windings. While the deleterious effect of metal in such cases is perhaps open to question, we have avoided its use as unnecessary in our design.

The transformer responds to wave-lengths as high as 2,500 meters without the loading inductance. This is believed to be the "happy medium" which reduces objectionable "dead ends" to a minimum and still affords a wave-

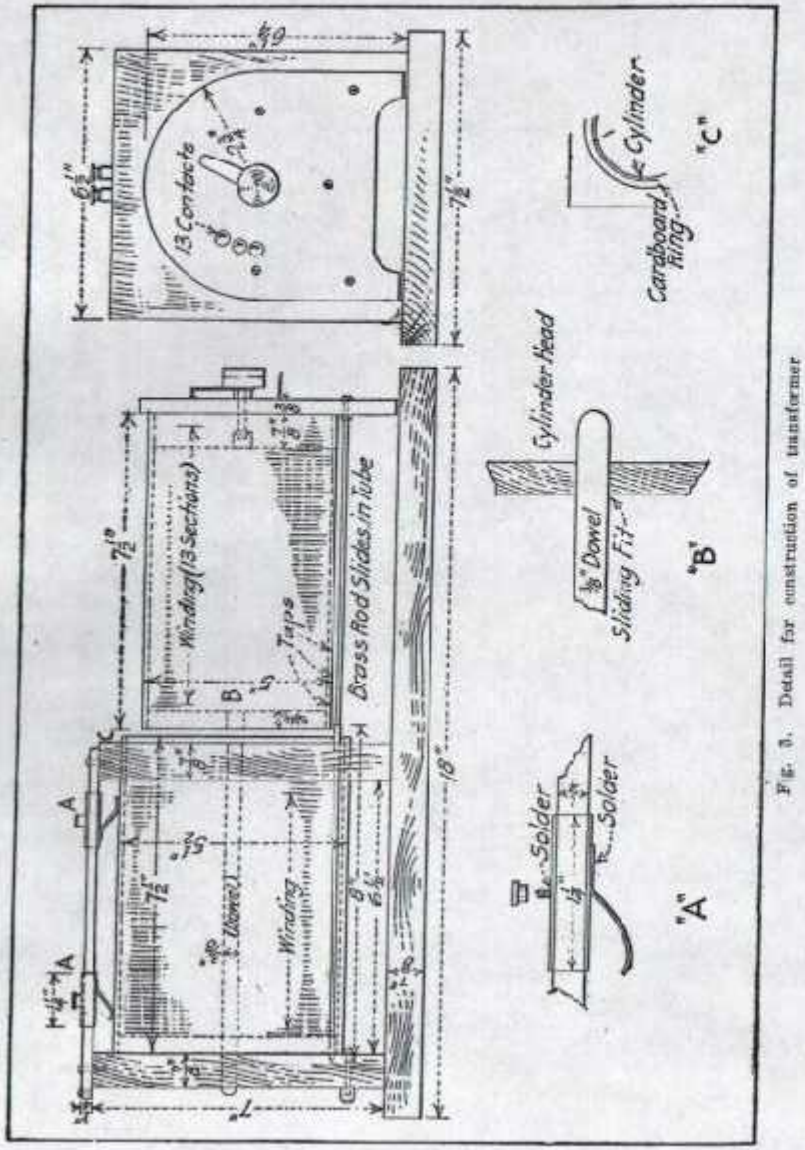

Fig. 3. Detail for construction of transformer

length of great utility. The figure quoted is based upon the use of the instrument with the average antenna of the advanced amateur.

The construction involves some careful but not necessarily difficult wood-working. A lathe is not at all necessary, although it is, as always, desirable. If a jig saw is available, most of the turning can be avoided. The only real, good excuse for a lathe is in turning the wooden heads that fit into the cardboard cylinders, and also in winding the cylinders. The latter operation may readily be done, however, by mounting the cylinders between centers on a base board. Another effective substitute for the lathe in both turning and winding operations is an ordinary polishing head that can be purchased for a couple of dollars. The discs may be mounted on the taper thread and a very presentable job of turning done with the broken end of a flat file held on a simple rest.

The jig saw, however, is an essential. If one of the foot-power variety is not available, the hand fret saw frame will answer, although in our experience there is no comparison between the two.

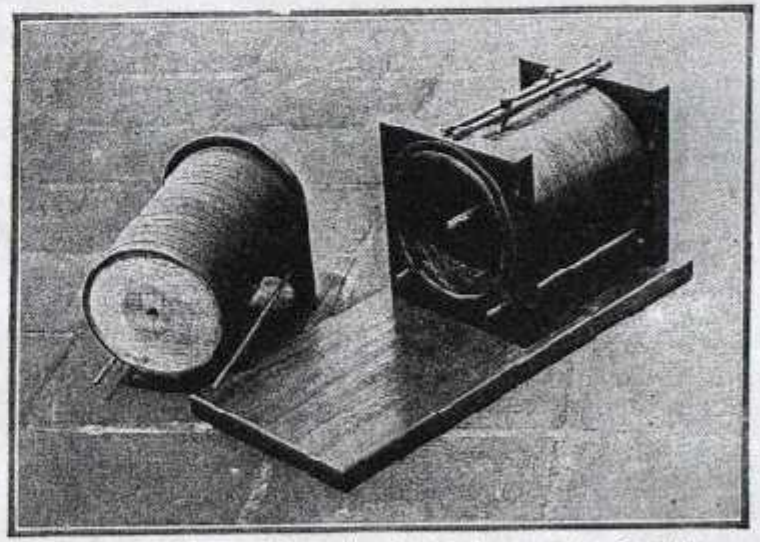

Fig. 2. Receiving transformer showing dowel arrangement for sliding

The woodwork had best be done first of all. Figs. 1, 2 and 3 will give a good idea of the appearance and construction of the in-

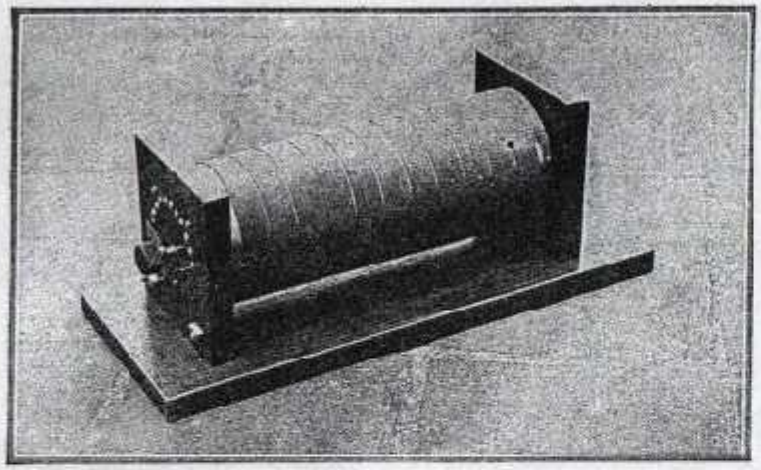

Fig. 4. Loading coil completed

cates, the secondary support is gripped between nuts and washers on the threaded ends of the rods.

We are now ready for the winding. The primary is wound directly upon a cardboard cylinder 5¼ in. diameter and 7⅛ in. long. The winding is No. 24 bare copper wire. The winding is done with two wires wound in parallel and then, after the ends are carefully secured by pushing through holes in the cylinder, and plugging with wooden pegs, one wire may be unwound. This will leave a firm, neat winding of bare copper wire with each turn separated from its neighbor by the thickness of the wire. The winding should be made about 5½ in. long, leaving ½ in. of space at either end of the cylinder when the latter is mounted in the wooden supports. After the winding is finished, it should be given two generous coats of shellac, taking care to see that the fluid runs down between turns in order that they may be sealed to the surface of the cylinder. The contact path for each slider is to be scraped in the winding after the shellac is quite hard and dry. This operation, however, need not be attempted until the cylinder is mounted and the sliders are in place on their rods.

The secondary winding consists of a single layer of No. 28 S. S. C. magnet wire wound in 13 sections upon a cardboard cylinder 5 in. diameter and 7½ in. long. The winding amounts to a single layer

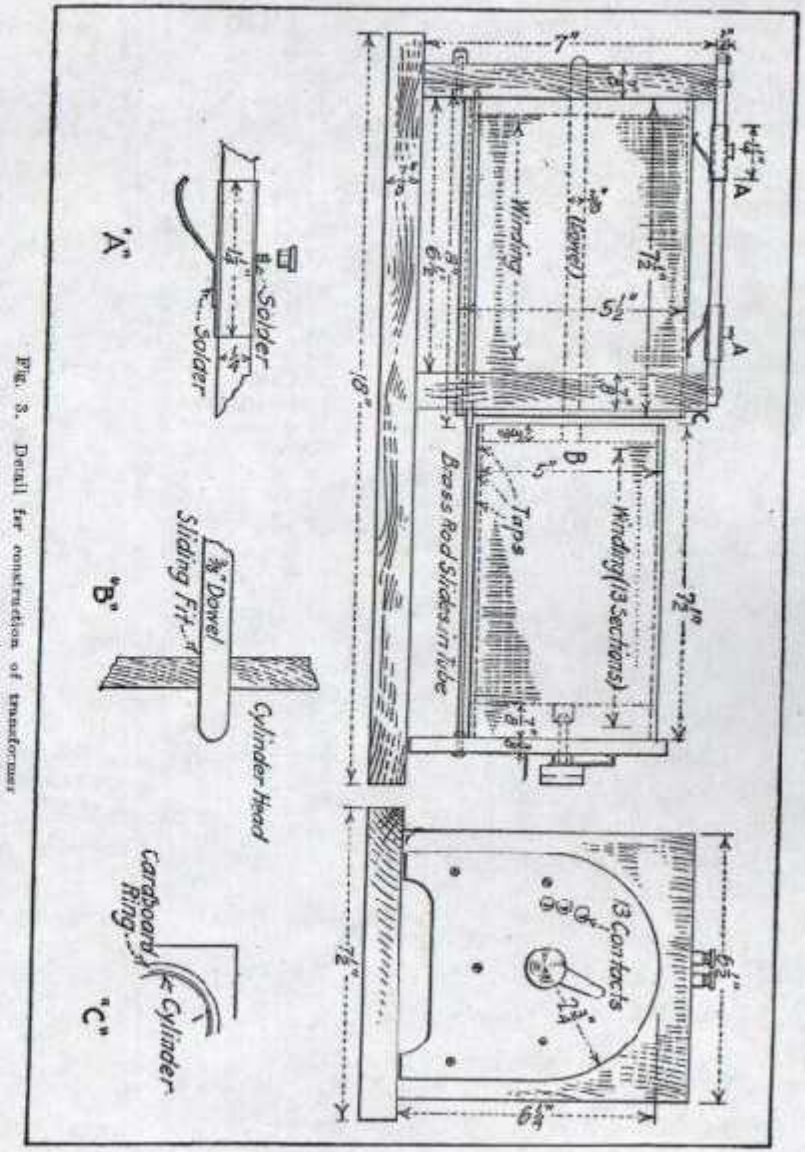

Fig. 3. Detail for construction of transformer

which is wound in the following manner: The winding is started from one end and continued for ½ in., at which point the hand guiding the wire is jumped to a distance which leaves a space of about 1-16 in. between the finished turn of the section just wound and the beginning of the next section. At the point where the "jump" is made a pin-hole is punched into the cardboard cylinder. Through this hole the tap which leads to the contact point will be made. This process is to be continued until 13 sections have been wound, at which point about 6½ in. of the surface of the cylinder will have been covered with the wire. Care must be taken to see that the holes through which the taps are taken are in a line, which will, of course, be at the bottom of the cylinder when it is mounted on the secondary support.

There are a number of ways of securing the silk-covered wire to the cardboard cylinder, but the best method in our experience is first to coat the cylinder with two or three applications of shellac, allowing the varnish to become "tacky" before placing the winding. This method will firmly secure each turn to the cylinder, and at the same time will obviate the necessity for shellacing the silk after the winding is complete.

The taps are made with lengths of slightly heavier bare copper wire pushed through the holes in the cylinder and soldered with a very fine copper, one to each of the "cross over" wires between sections. These taps should be long enough to extend through the ⅞ in. head to make contact with the points upon which the instrument switch bears. Each tap is to be covered with a sleeve of fine rubber tubing to prevent possible short circuits inside the cylinder.

The next operation, before going further with the taps, is to insert the secondary inside the primary after having wound heavy wrapping paper around the primary until it fits closely into the larger tubing. The secondary support with its brass rods firmly secured to it is then to be brought up to the wooden head of the secondary and holes drilled for the wood screws that secure the secondary to the support. The shrewd reader will at once see that this insures accuracy in assembling the component parts of the transformer and precludes the possibility of uneven space between primary and secondary cylinders. When the screws have been driven home, the secondary may be withdrawn and from this point on the secondary and its supporting piece should not be separated.

The next operation will be to lay out the arc of the circle for the contact points, of which there are 13. The radius of the arc on

strument. The details and dimensions are given in Fig. 3. The choice of wood rests with the individual, but we favor whitewood. The base, 7½ in. wide and 18 in. long, is of ⅞ in. stock and quite simple. The upright pieces that support the primary are each 6½ in. wide and 7 in. high, while the thickness may be ⅞ in. The piece to the right in Fig. 3 is cut out to receive the cardboard cylinder which is 5½ in. outside diameter. The left-hand piece is left solid and it has mounted upon it a disc of ⅜ in. whitewood turned to fit the inside of the cylinder. The latter should not be permanently secured in its supports until after the holes for the brass tubes indicated in the drawing have been drilled. This operation will be detailed later.

The next step will be to get out the two discs for the secondary cylinder. One of these is of ⅜ in. stock, while the other is of ⅞ in. wood. They are, of course, to fit the inside of the cylinder tightly. The latter, as the drawing indicates, is 5 in. in outside diameter. The internal diameters of both cylinders will vary a trifle with different makes of cardboard tubing, but it is of little consequence. The thicker disc may be permanently affixed by means of glue and wooden pegs, but the thinner disc must be left removable until after the winding is finished and connections to the contact points are made.

The front support that holds the secondary may now be worked out with the jig saw, and with this the woodwork proper is finished. This is the time to do the staining and varnishing. If these decorative operations are left until later, the results will be rather unsatisfactory and the task difficult to perform. After the varnish is good and hard, so that handling will not injure the finish, the worker may lay out the centers for drilling the two holes through which pass the supporting brass rods. These holes are 4⅜ in. apart on centers and 1¼ in. up from the base. When the centers have been marked and pricked, the front support may be placed on two pieces which hold the primary, and holes drilled through all three while they are clamped together. This will insure alignment of the holes, which is quite essential to prevent binding when the rods are telescoped into the tubes. The holes in the secondary support may be ¼ in., the same as those in the other pieces, for a trifle of leeway is not objectionable to permit of easing up on any bind that may develop when the apparatus is assembled.

The brass tubing and the rods that enter it may then be placed, and the whole arrangement assembled temporarily to determine whether the work has been successful. As the drawing indi

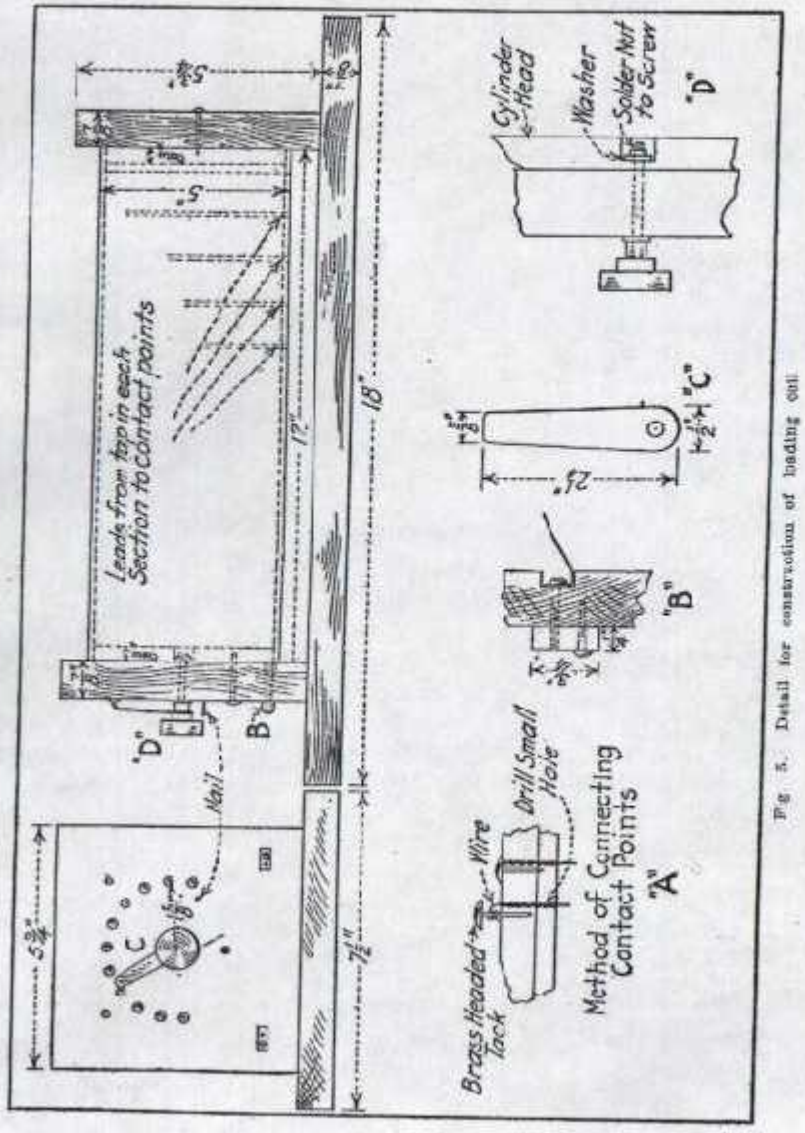

Fig 5. Detail for construction of loading coil

shape, and soldered to the bottom of the slider.

Binding posts are not specified, for connection may be made directly to machine screws in the ends of the slider rods in the case of the primary, and to small connection blocks electrically connected with the brass tubes that pass through the primary supports, for the secondary.

Loading Inductance

The loading inductance consists of a cardboard cylinder wound in a single layer with No. 24 S. S. C. copper magnet wire in 11 sections. Each section is tapped to a contact point in one of the heads as shown in the illustration. As the construction is identical with that of the receiving transformer just described, in so far as mounting the cardboard cylinder, etc., is concerned, we will not go into a lengthy explanation of the construction. All details are given very clearly in Fig. 5, and Fig. 4 shows well the appearance of the finished instrument.

A few hints relative to the standard products used in the construction of both of these coils may not be amiss. The instrument switch used on each coil is a standard product that may be bought in almost any large supply house. The builder is, however, advised to discard the usual brass contact piece and substitute for it a piece of phosphor bronze sheeting cut to the dimensions shown at *C*, Fig 5, and bent over at the tip so that the contact is made on the edge rather than on the flat surface.

The contact points may be ordinary brass-capped upholstery tacks or they may be oval-head copper rivets. The latter are much to be preferred, but they are more expensive and more difficult to install. If the rivets are used, however, the hole through which the tap wire passes may be made approximately the same size as the shank of the rivet in order that the latter may make contact as the stud is driven home.

If the upholstery tacks are used, the method of connecting shown at *A* should be employed. This insures contact between the wire and the brass head rather than with the steel shank of the tack.

The simple form of connection block that we favor is shown at *B*. This is merely a short length of ¼ in. square brass rod secured to the instrument at the desired point. Connection is made under the heads of brass machine screws in an obvious manner.

The cardboard cylinders for both receiving transformer and loading coil may be obtained from advertisers in this magazine, and the woodwork is best obtained from a local mill which will cut out the pieces to size at a very reasonable figure.

At *D* is shown the method we employ to secure the adjusting

knob which carries the switch making contact with the studs. In the standard product a threaded shank is permanently fastened to the composition knob. The obvious way of securing this switch to the instrument would be merely to place a lock-nut over the first nut that goes on the shank. This method, however, is unreliable and unsatisfactory. Constant use will frequently loosen the nuts after the instrument is entirely assembled, and needless annoyance results therefrom. We used the simple expedient of locking the first nut with a drop of solder after we had secured just the tension we desired to make the knob turn with freedom but without unpleasant looseness.

The *Technical Adviser* is at the disposal of readers who require additional advice or instructions, and the *Service Department* will aid those who have difficulty in obtaining needed materials.

Paint For One Cent Per Pound

To one gallon of hot, soft water add four pounds of crude sulphate of zinc. Let it stand until it dissolves perfectly, and a sediment will settle at the bottom. Turn the clear solution into another vessel. To one gallon of paint (lead and oil) mix one gallon of the compound. Stir into the paint slowly for 10 or 15 minutes and the paint and compound will combine perfectly. If too thick, thin the mixture with turpentine.

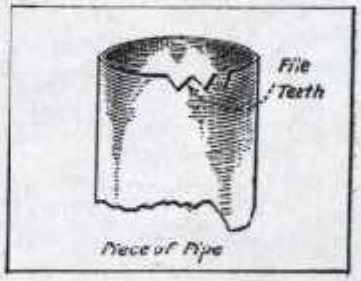
Boring a Hole in Brick

Any man who wishes to bore a hole in brick and has not a cold chisel on hand will find this home-made chisel very handy. All that it consists of is a piece of galvanized iron pipe about 7 in. long and the diameter de-



File teeth in one end of the pipe

pends upon the hole you want to bore. In one end of this pipe teeth must be filed about 1-16 in. apart. You will find that this will bore a clean-cut hole.

1. Introduction

Thank you for purchasing this high performance single-band 5W CW transceiver kit, the QCX (for **Q**RP Labs **C**W **X**cvr). This kit has a long list of features!

- Easy to build, single-board design, 10 x 8cm, all controls are board-mounted
- Professional quality double-sided, through-hole plated, silk-screen printed PCB
- Choice of single band, 80, 60, 40, 30, 20 or 17m
- Approximately 3-5W CW output (depending on supply voltage)
- 7-16V recommended supply voltage
- Class E power amplifier, transistors run cool… even with no heatsinks
- 7-element Low Pass Filter ensures regulatory compliance
- CW envelope shaping removes key clicks
- High performance receiver with at least 50dB of unwanted sideband cancellation
- 200Hz CW filter with no ringing
- Si5351A Synthesized VFO with rotary encoder tuning
- 16 x 2 blue backlight LCD screen
- Iambic keyer or straight key option included in the firmware
- Simple Digital Signal Processing assisted CW decoder, displayed real-time on-screen
- On-screen S-meter
- Full or semi QSK operation using fast solid-state transmit/receive switching
- Frequency presets, VFO A/B Split operation, RIT, configurable CW Offset
- Configurable sidetone frequency and volume
- Connectors: Power, 3.5mm keyer jack, 3.5mm stereo earphone jack, BNC RF output
- Onboard microswitch can be used as a simple straight Morse key
- Built-in test signal generator and alignment tools to complete simple set-up adjustments
- Built-in test equipment: voltmeter, RF power meter, frequency counter, signal generator
- Beacon mode, supporting automatic CW or WSPR operation
- GPS interface for reference frequency calibration and time-keeping (for WSPR beacon)

No test equipment is required to build, align and operate this CW transceiver. Its innovative self-alignment and self-test features will help and guide you in setting up the transceiver in a few easy steps. The kit also includes a voltmeter, RF power meter, frequency counter and signal generator which can aid in debugging and fault-finding.

We hope you enjoy building and operating this kit! Please read this assembly manual carefully, and follow the instructions step by step in the recommended order. Later in the manual the circuit design is described in detail and we recommend reading and understanding this section too, to get the maximum enjoyment and education from your new radio.

Typical performance measurements are shown in the measurements section. The operation section of the manual describes transceiver, alignment and test equipment operation in detail. **There is a single page reference "cheat sheet" near the end of the manual.**

2. Parts list

Resistors (all fixed resistors are ¼-Watt, 1% tolerance)

R5, R6, R8, R9	100-ohm (4 pcs), brown-black-black-black-brown
R48	270-ohm, red-purple-black-black-brown
R41	470-ohm, yellow-purple-black-black-brown
R3, 4, 19, 26, 37, 42, 45, 53-55, 62, 63	1K (12 pcs), brown-black-black-brown-brown
R12, 13, 15, 16, 20, 22, 23, 25, 44, 56, 59	3.3K (11 pcs), orange-orange-black-brown-brown
R61	3.9K, orange-white-black-brown-brown
R18	4.3K, yellow-orange-black-brown-brown
R11	5.1K, green-brown-black-brown-brown
R21	7.5K, purple-green-black-brown-brown
R1, 2, 7, 10, 14, 34, 39, 40, 46, 49-52, 57, 58	10K (15 pcs), brown-black-black-red-brown
R28, 29	33K (2 pcs), orange-orange-black-red-brown
R30, 31	47K (2 pcs), yellow-purple-black-red-brown
R32, 33	36K (2 pcs), orange-blue-black-red-brown
R38, 43, 60	120K (3 pcs), brown-red-black-orange-brown
R35	750K, purple-green-black-orange-brown
R27	500-ohm multi-turn trimmer potentiometer
R17, 24	50K multi-turn trimmer potentiometer (2 pcs)
R36	5K Logarithmic potentiometer
R47	100K trimmer potentiometer

Capacitors

C5	22pF, “220” (not used on every band version)
C30	30pF, “300” (not used on every band version)
C8	39pF, “390” (not used on every band version)
C14, 16, 18, 23, 33	1nF, “102”, (5 pcs)
C19, 20	2.2nF, “222” (2 pcs)
C53	3.3nF, “332’
C4, 7, 10, 42	10nF, “103” (4 pcs)
C15	33nF, “333”
C17	39nF, “393”
C9, 13	47nF, “473” (2 pcs)
C2, 3, 6, 12, 29, 32, 34-36, 39-41, 48-50, 52	0.1uF, “104” (16 pcs)
C11, 43-46	470nF, “474” (5 pcs)
C31	1uF, “105”
C21, 22, 24, 37, 38, 51	10uF electrolytic (6 pcs)
C47	470uF electrolytic
C25, C26	Value depends on band, in LPF kit bag (2 pcs)
C27, C28	Value depends on band, in LPF kit bag (2 pcs)
C1	30pF trimmer

Semiconductors

D1, 2, 4, 5	1N4148 (4 pcs)
D3	1N5819

IC1	SI5351A 10-pin MSOP (pre-soldered at factory)
IC2	ATmega328P 28-pin microcontroller
IC3	74ACT00N 14-pin quad NAND gate
IC4	FST3253 16-pin SOIC (pre-soldered at factory)
IC5-10	LM4562 8-pin dual op-amp (6 pcs)
IC11	7805, TO220 5V 1A voltage regulator
Q1-5, 7	BS170 TO92 MOSFET (6 pcs)
Q6	MPS751 TO92 transistor (MPS2907 in early kits)

Inductors

L1, 3	Value depends on band, in LPF kit bag (2 pcs)
L2	Value depends on band, in LPF kit bag
L4	T37-2 (red) toroid, value depends on band
L5, 6	100uH axial molded inductors (2 pcs)
T1	T50-2 (red) toroid, value depends on band

Miscellaneous

2 x 3-pin	Male header connector for in-circuit programming
4-pin	Male header connector, in LPF kit bag (2 pcs)
16-pin	Male header connector
16-pin	Female header connector
2-pin terminal block	2-pin screw terminal block
3.5mm stereo	3.5mm stereo connector (2pcs)
BNC	PCB-mounting BNC connector
S1	Microswitch
S2, 3	6 x 6mm push-to-make button (2 pcs)
SW1	Rotary encoder with shaft push-button
16 x 2 LCD	HD44780 LCD 1602 with blue backlight
XTAL1	20MHz HC49/4H quartz crystal
XTAL2	27MHz HC49/4H quartz crystal
PCB	4.0 x 3.2-inch PCB (101.6 x 81.3mm)
spacer	12mm M3 nylon hex spacers (8 pcs)
screw	6mm M3 nylon screws (12 pcs)
Knob	Knobs to fit rotary encoder and R36 (2 pcs)

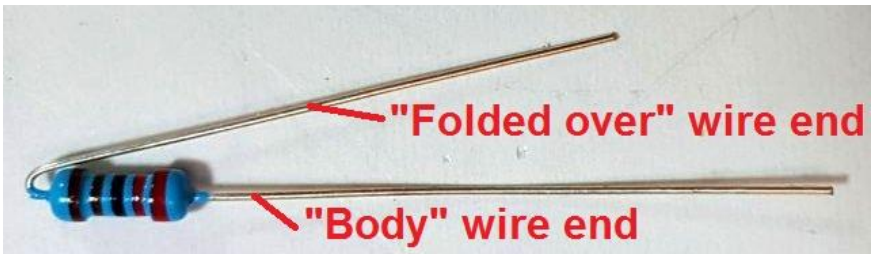
3. Assembly

Assembly of this kit is quite straightforward. But there are quite a lot of components. So please keep them methodically in trays or some convenient storage boxes, and be careful not to misplace any. The usual kit-building recommendations apply: work in a well-lit area, with peace and quiet to concentrate. **The IC (chips) and some of the other semiconductors in the kit are sensitive to static discharge. Therefore, observe Electrostatic discharge (ESD) precautions**. And I say it again: **FOLLOW THE INSTRUCTIONS!!** Don't try to be a hero and do it without instructions!

A jeweller's loupe is really useful for inspecting small components and soldered joints. You'll need a fine-tipped soldering iron too. It is good to get into the habit of inspecting every joint with the magnifying glass or jeweller's loupe (like this one I use), right after soldering. This way you can easily identify any dry joints or solder bridges, before they become a problem later on when you are trying to test the project.

Triple check every component value and location BEFORE soldering the component! It is easy to put component leads into the wrong holes, so check, check and check again! It is difficult to de-solder and replace components, so it is much better to get them correctly installed the first time. In the event of a mistake, it is always best to detect and correct any errors as early as possible (immediately after soldering the incorrect component). Again, a reminder: removing a component and re-installing it later is often very difficult!

All of the resistors in the kit are installed vertically, because PCB space is limited. You will need to bend the resistor wires as shown in the picture below. On the parts layout diagram, there is a small circle around the hole where the body end of the resistor should be installed. This is not critical (resistors don't care which way around they are) but it is recommended, just to try to ensure that the folded over wire-end of the resistor doesn't touch any other wire or metal part.



Please refer to the layout diagram and PCB tracks diagrams below, and follow the steps carefully.

Assembly steps will be in the order of smallest to largest components. I follow the order semiconductors, capacitors, resistors and finally all other (generally larger) components. It is probably unnecessarily thorough and complex to build the radio one stage at a time and test each stage one by one… I recommend just install everything then power up.

As per standard QRP Labs practice, the ATmega328P microcontroller has a 28-pin DIP socket in case you may wish to subsequently replace it for firmware upgrades etc. The Si5351A and FST3253 ICs are only available in surface mount packages so these are already soldered to the PCB for you, at the factory. All other components used are all leaded through-hole packages, and all are installed on the top side of the PCB.

Some people like using IC sockets, some don't. Undoubtedly there is a cost impact, of course. Personally, I believe that on average, the use of IC sockets causes more problems than it solves. They create the potential for bent pins that don't make contact properly, hidden shorts under the socket, issues with increased lead length, etc. Accordingly, the remaining ICs are soldered directly into the PCB without IC sockets. Please forgive me if you disagree.

You may find it convenient to inventory the resistors and capacitors and sort them by value, so that you can easily find the correct ones as you work through the assembly steps.

The PCB track and circuit (schematic) diagrams are shown on the previous pages. Tracks shown in BLUE are on the bottom layer. Tracks shown in RED are on the top layer. There are only two layers (nothing is hidden in the middle). Not shown in this diagram are the extensive ground-planes, on both sides of the board. Practically everything on both layers that isn't a RED or BLUE track, is ground-plane! The two ground-planes are connected at frequent intervals (not more than 0.1-inches) by vias. This is the kind of layout I have done previously for a quad-band GSM device operating at up to 1900MHz… it is probably overkill in an HF transceiver… but if you can, why not! I used to say often that you can never have too much supply line filtering and decoupling, and never have too much shielding. Both these statements don't apply so conveniently to kits as they do to homebrew projects. In a kit every decoupling capacitor has a cost in both money and PCB area (which also means more money). Shielding is even more difficult and expensive. So shielding and decoupling should be applied where needed only! But ground-plane – well that's another story. It's free, and without drawbacks – so why not, let's just put it everywhere.

The PCB silkscreen component numbers are necessarily quite small and may be overlapping pads or vias, or near to other components. It may be nice to have doubled the size of the PCB and have more space to print nice silkscreen labels of the component numbers. But the result wouldn't be such a cute and neat little radio and the price wouldn't be so friendly either! So check carefully, before soldering each component! Check the location and check again – with reference to the diagrams in each step.

All components are installed on the top (component side) of the PCB and soldered on the bottom (solder side) of the PCB.

Take care when installing integrated circuits. All through-hole integrated circuits are supplied by the manufacturers with their pins bent a little wide. You need to carefully bend the rows of pins together a little, in order to fit them in the PCB holes, or in the 28-pin IC socket in the case of the ATmega328P microcontroller.

The band-specific Low Pass Filter (LPF) parts are supplied in a separate LPF kit bag.

In the construction for some bands, not all of the capacitors supplied in the kit are used. Do not be alarmed if you have a few components left over at the end!

Wind the L1-3 inductors with the enamelled copper wire supplied in the LPF kit bag. Wind the other inductors (L4 and transformer T1) using the wire supplied in the main kit bag.

The component colour coding of the layout diagram at every step of the assembly instructions is as follows (kind of: components past, present and future):

- Components shaded grey have already been installed
- Components shaded red are the ones being installed in the current assembly step
- Components shaded white are the ones which have not yet been installed

The following photographs show the final assembly, with and without the LCD module plugged in. You can keep these photographs in mind when assembling the kit, they will give you some idea of how the kit fits together and help avoid assembly errors.

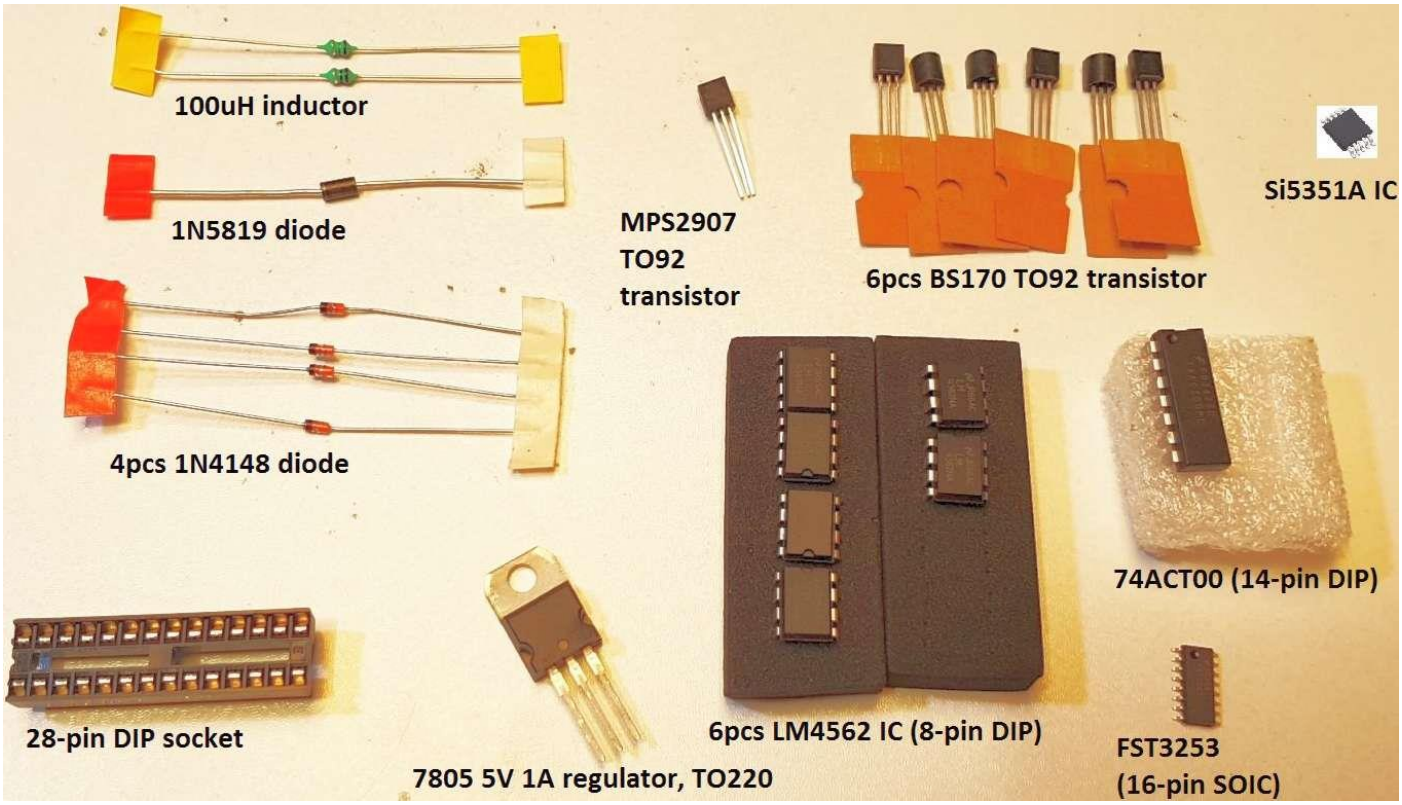
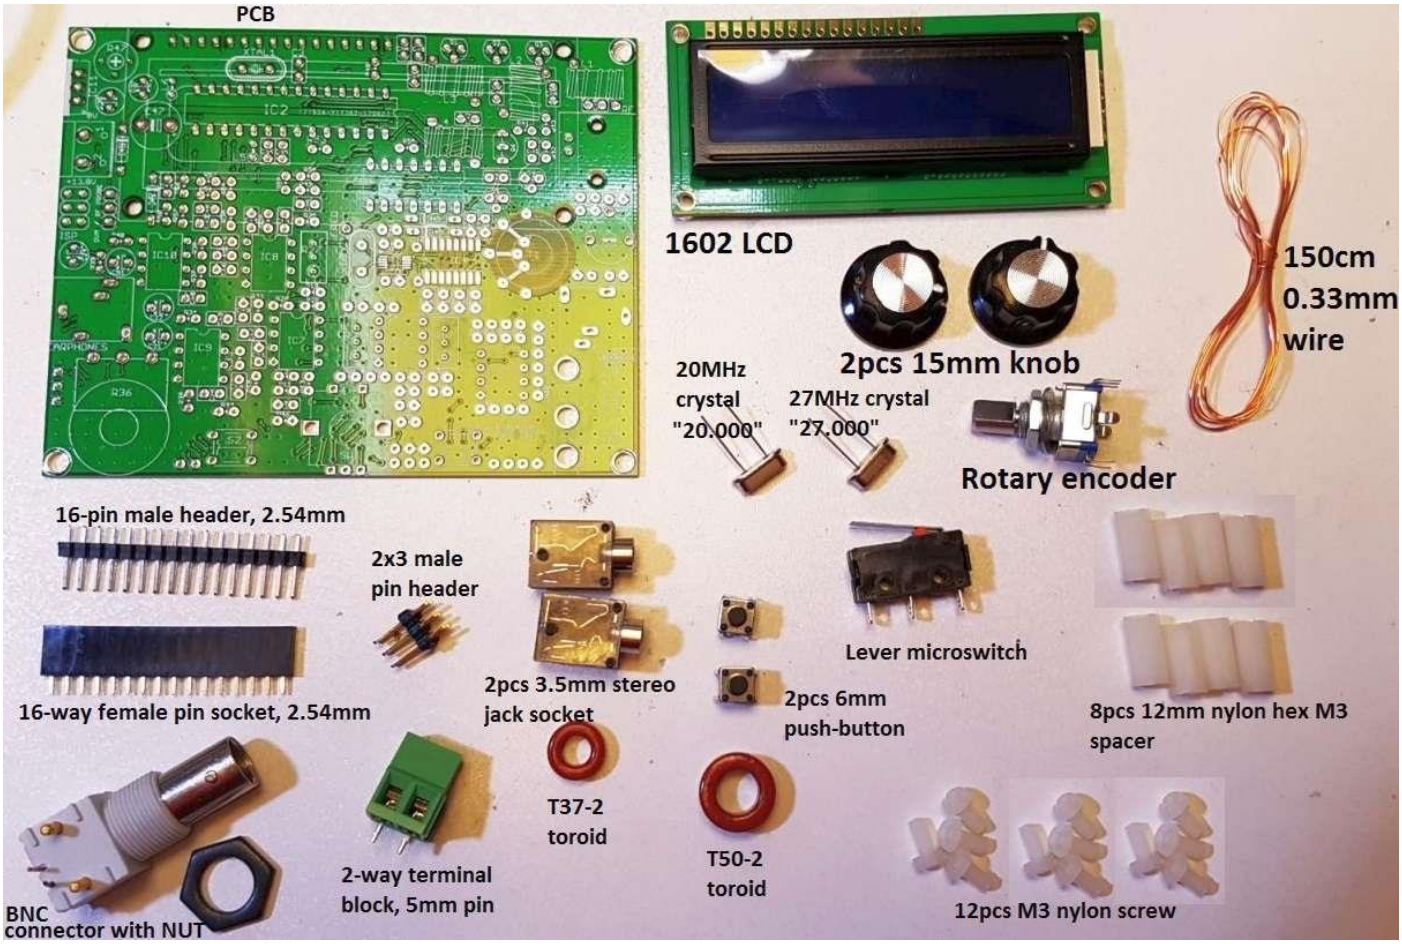
3.1 Inventory parts

Refer to parts list in section 2. The following photographs are to aid component identification. The resistors and capacitors are omitted.

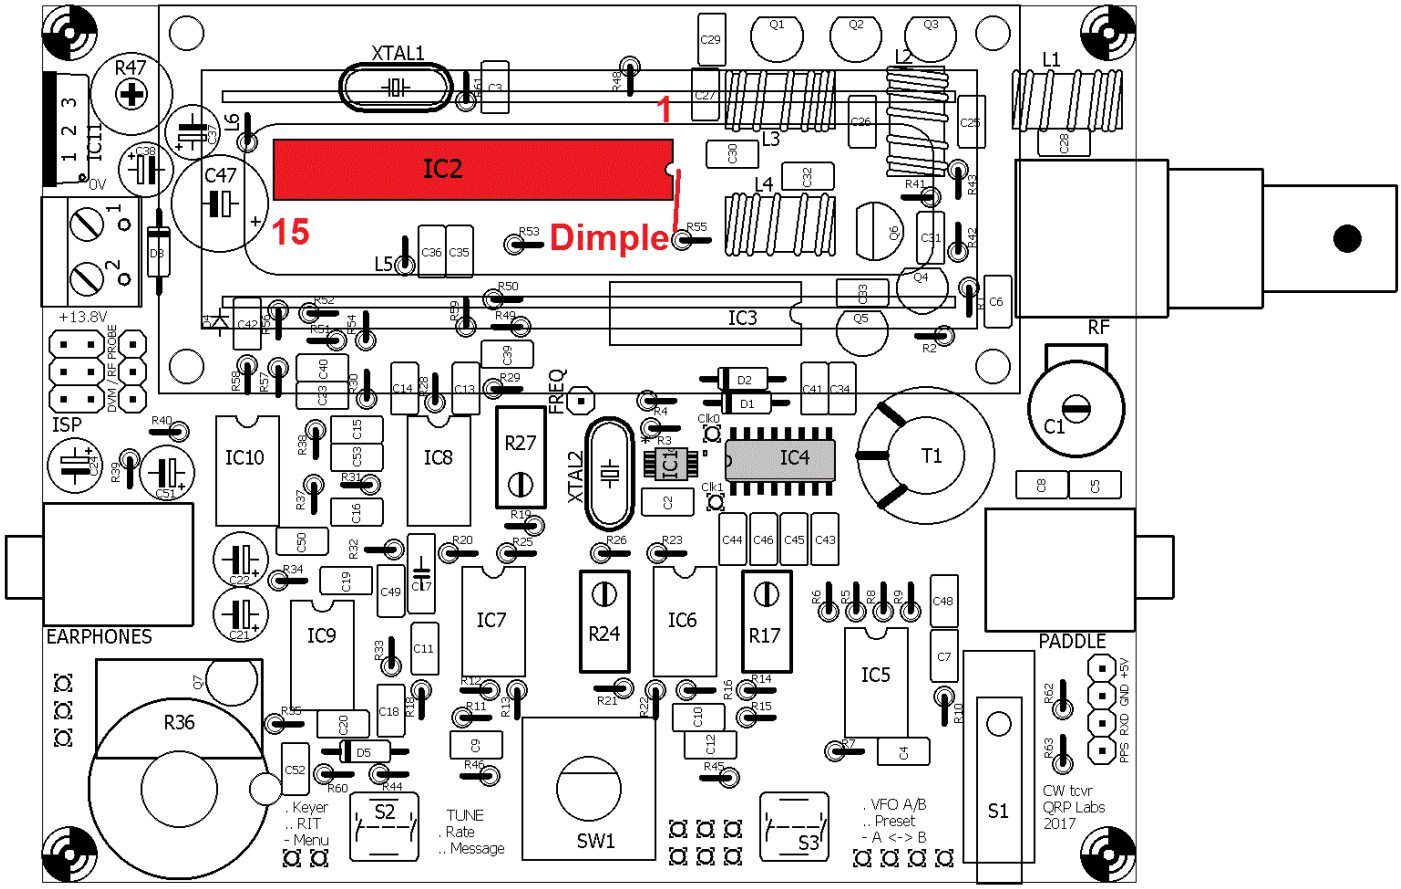




3.2 Install IC2 socket

Install the 28-pin IC socket for IC2. Take care to match the dimple on the socket, with the dimple on the PCB silkscreen. It is critical to insert the microcontroller with the correct orientation. Lining up the dimple on the PCB silkscreen, socket and actual IC is the best way to avoid confusion and potential error.

I recommend soldering one pin at each diagonal, for example pins 1 and 15. You can then check that the IC socket is seated firmly on the PCB, and correct any issues easily. Once all the pins are soldered it will be difficult, if not impossible, to change anything. When you are happy with the position of the socket, proceed with soldering the other 26 pins.



3.3 Install DIP integrated circuits IC3, IC5-10

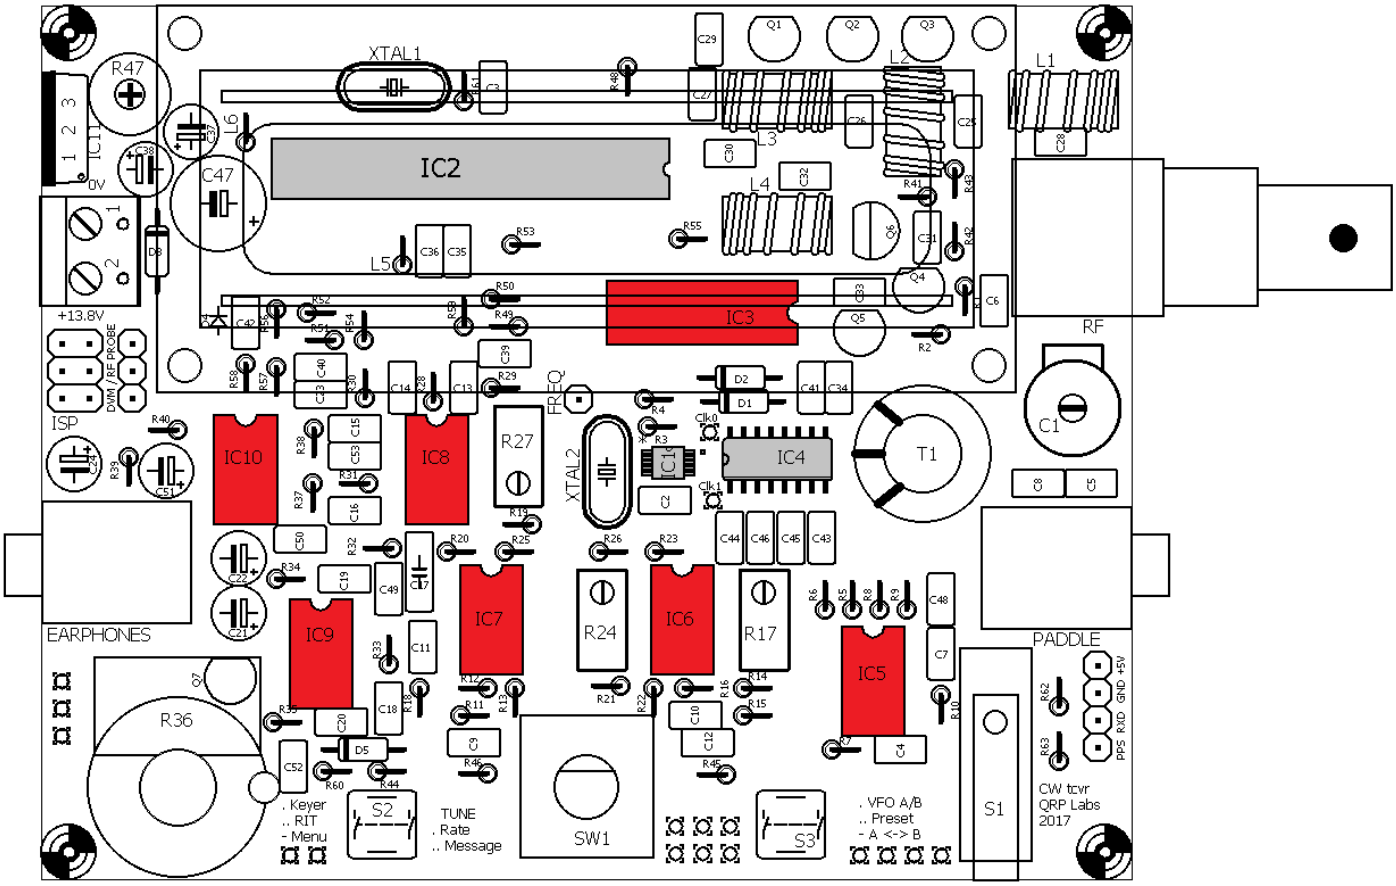
In the same way, install the Dual-Inline-Package integrated circuits IC3 and IC5-10. We install these now because they have more pins than all the passive components (resistors, capacitors etc) and it is easiest to reach and install the ICs properly when they are alone on the board. All of the operational amplifier ICs (IC5-IC10) are part number LM4562, so it is impossible to mix them up, they are the only 8-pin DIP chips in the kit. Similarly, IC3 is the only 14-pin DIP chip.

Electrostatic Discharge (ESD) precautions should be observed though personally I do not think it is necessary to get crazily paranoid about this. Don't wear 100% nylon clothing and dance around on a nylon carpet etc to build up static charge! But I don't go to the other extreme of earth mats, earthed wrist bands etc.

It IS absolutely critical to align the IC's properly! Be very careful to check and double-check and even triple-check that the dimple in each IC package is aligned with the dimple in the silkscreen print on the PCB (and the layout diagram).

It is normal to need to slightly squeeze the rows of pins inwards to fit in the holes on the PCB. IC manufacturers always supply leaded (through-hole) ICs with the pins a little too wide-spaced.

As before, I find it useful to solder initially two pins at diagonal opposites of the chip, then check that the chip is nicely seated evenly on the board, before soldering the other pins.

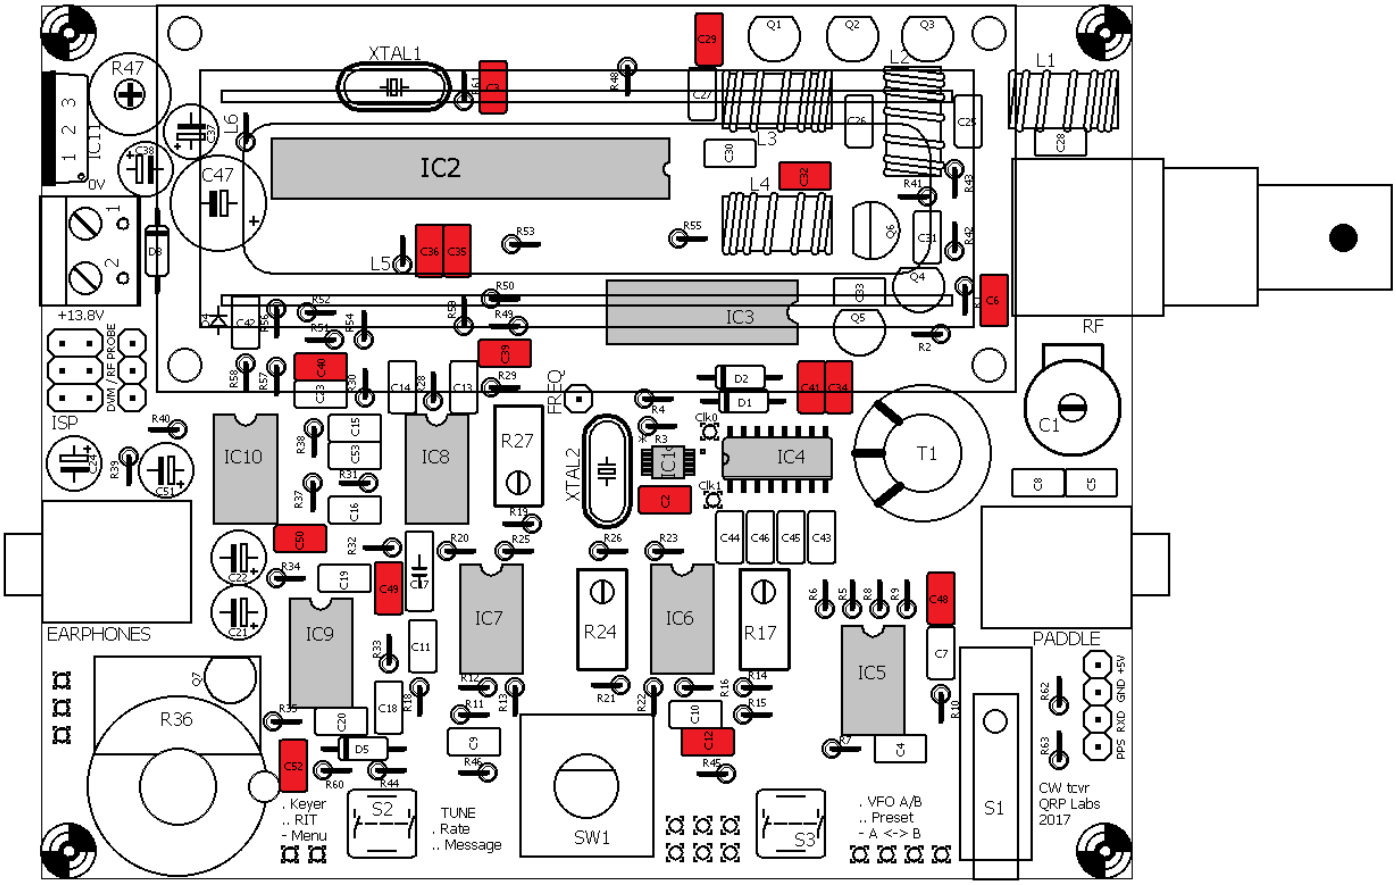


3.4 Install all 100nF (0.1uF, “104”) capacitors

There are 16 100nF (0.1uF) capacitors, these have the code “104” written on them. Be sure to identify the correct capacitors, using a magnifying glass or jeweller’s loupe. These capacitors are C2, C3, C6, C12, C29, C32, C34, C35, C36, C39, C40, C41, C48, C49, C50 and C52. Place each in the correct position on the board, and slightly bend the legs outwards at about 30-degrees angle so that they stay in place. Then solder the wires, and trim the excess wire length with wire cutters.

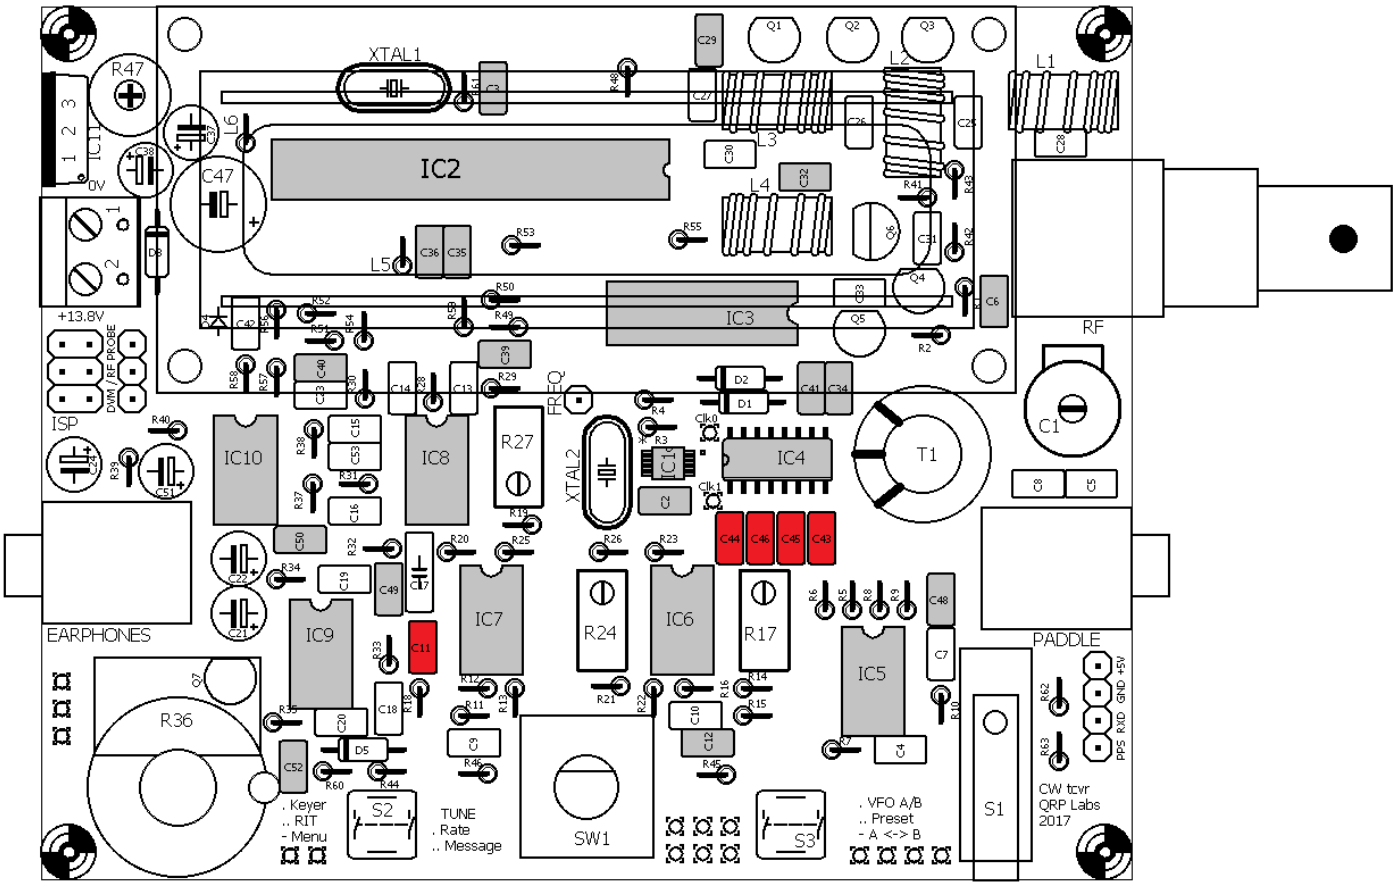
It does not matter which way round the capacitors are installed. However, it is very good practice to install them all with the capacitor label facing in the same direction. For example, ensure all the “104” labels face to the front, or to the right (depending which way the capacitor is orientated on the PCB). This makes it much easier to inspect the PCB assembly later.

Take particular care soldering wires which connect to the ground plane. Despite the “thermals” (a ground pad is connected to the ground plane by four thin traces, not a continuous ground plane, to make soldering easer), the heat dissipation is still more, and it can be harder to make a good joint.



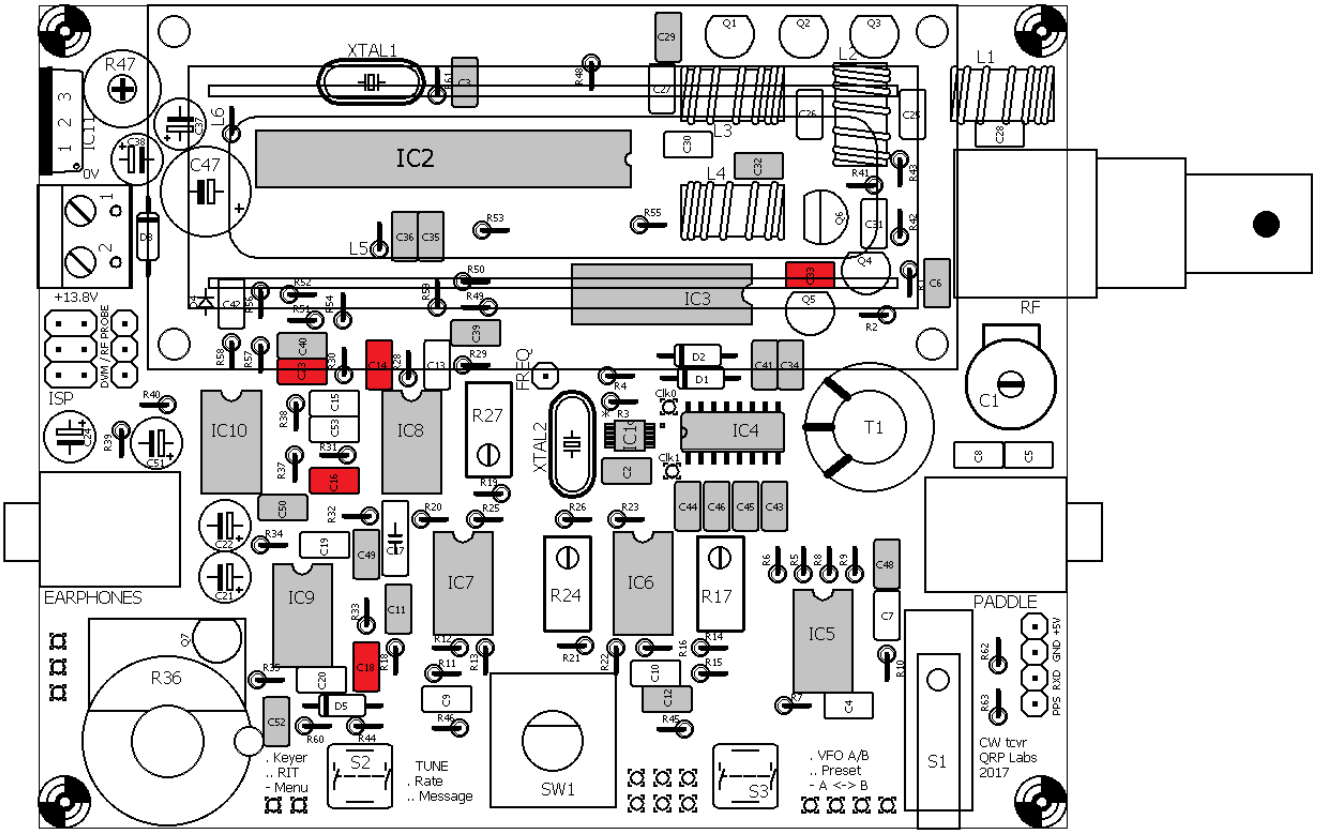
3.5 Install all 470nF, “474” capacitors

The 470nF capacitors are labelled “474”, and are capacitors C11, C43, C44, C45 and C46.



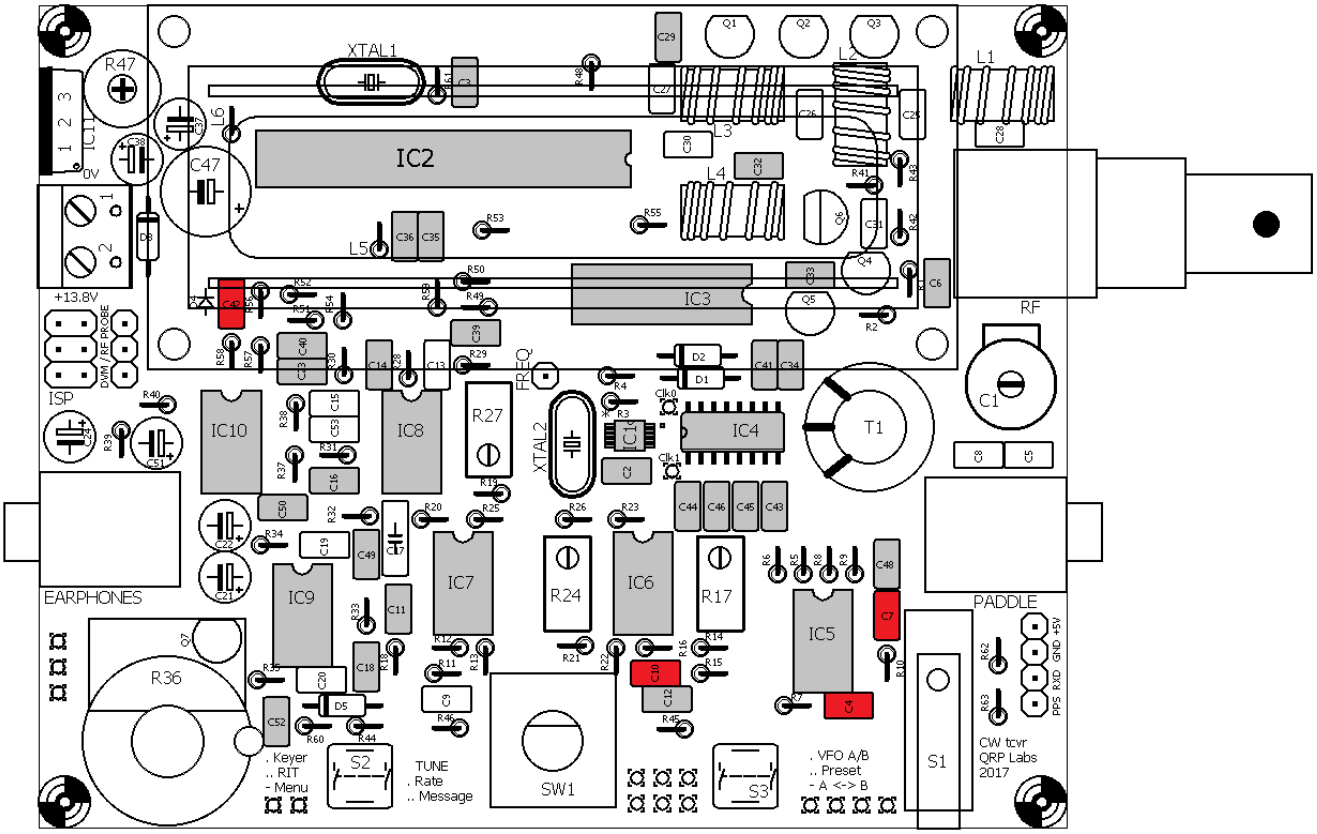
3.6 Install all 1nF, “102” capacitors

The 1nF capacitors are labelled “102” and are capacitors C14, C16, C18, C23 and C33.



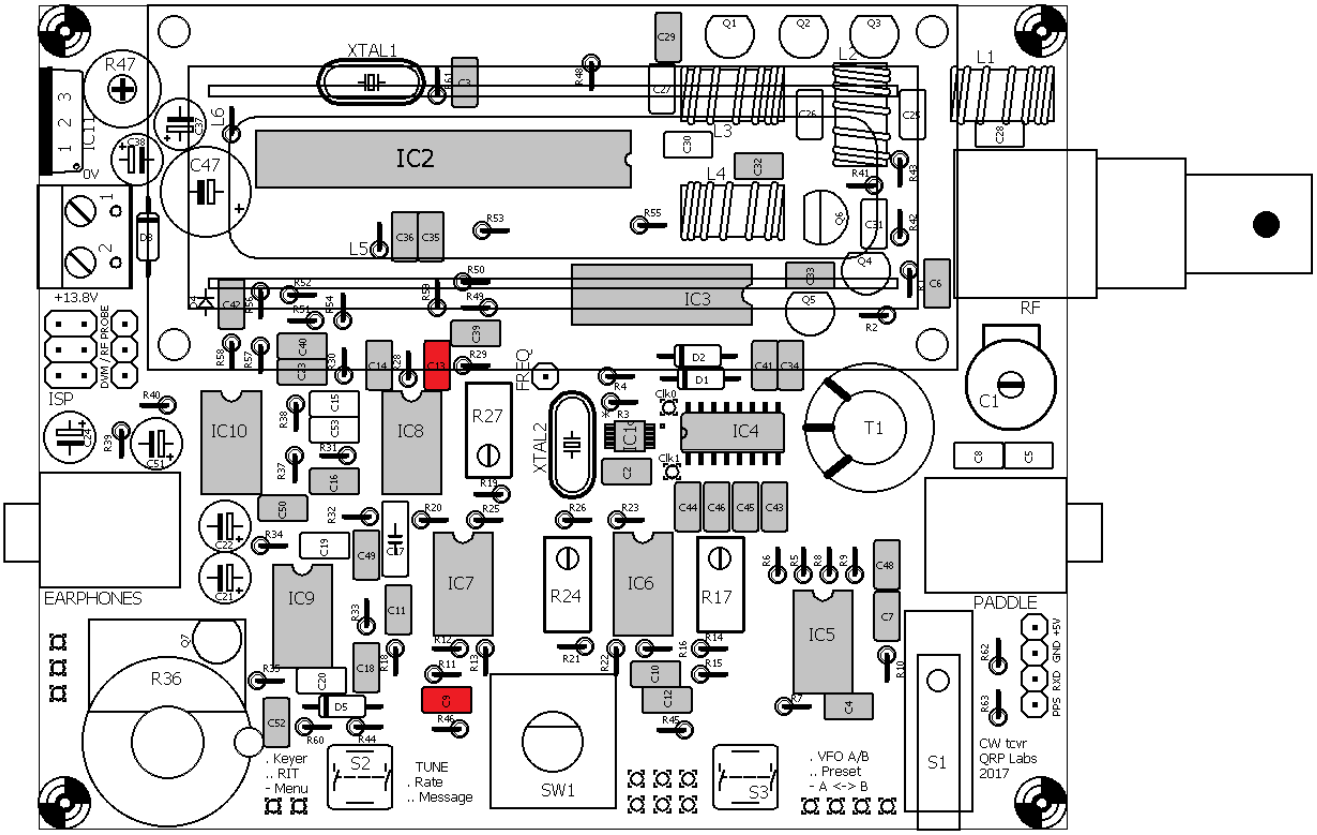
3.7 Install all 10nF, “103” capacitors

The 10nF capacitors are labelled “103” and are capacitors C4, C7, C10 and C42.



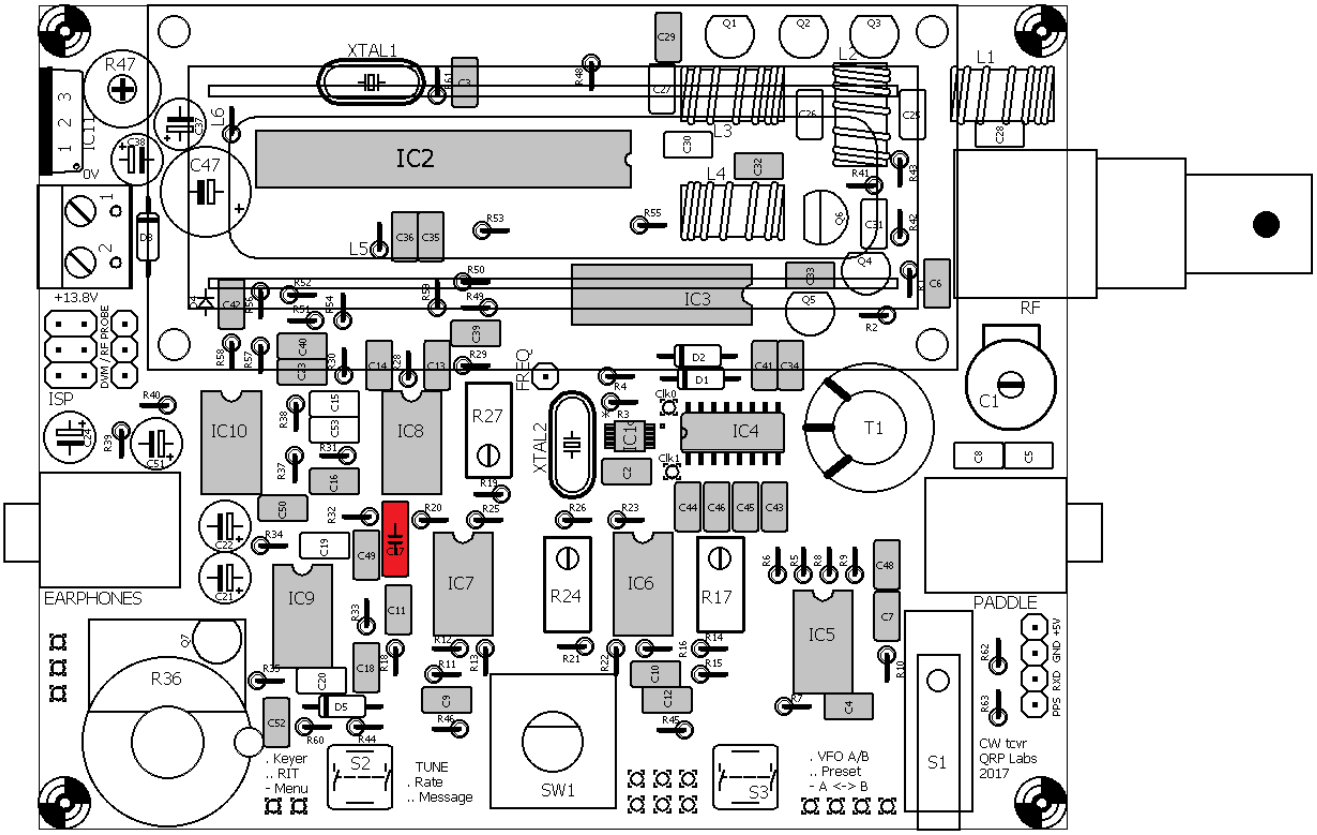
3.8 Install 47nF, “473” capacitors

The 47nF capacitors are labelled “473” and are capacitors C9 and C13.



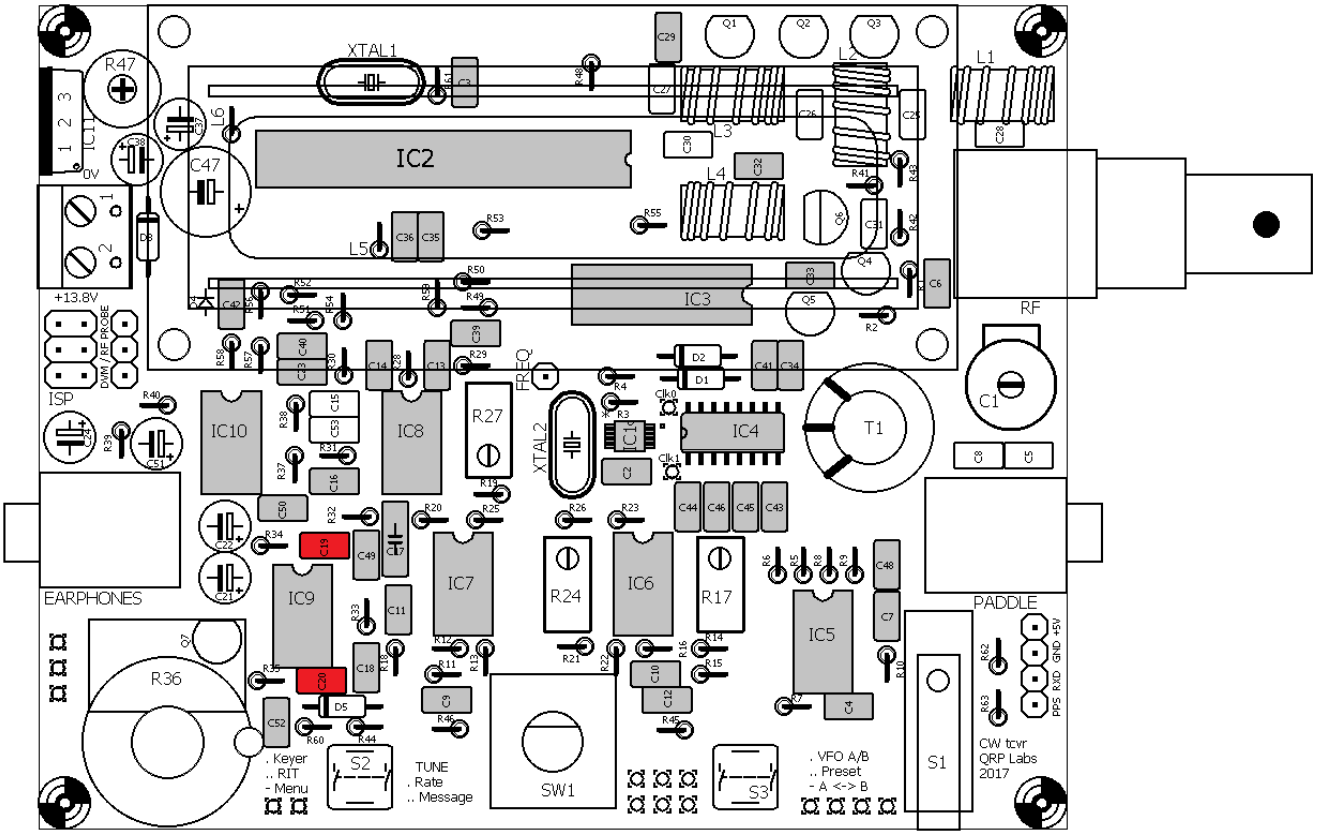
3.9 Install 39nF, “393” capacitor

The 39nF capacitor is labelled “393” and is C17. It has 5mm pin spacing, unlike the others.



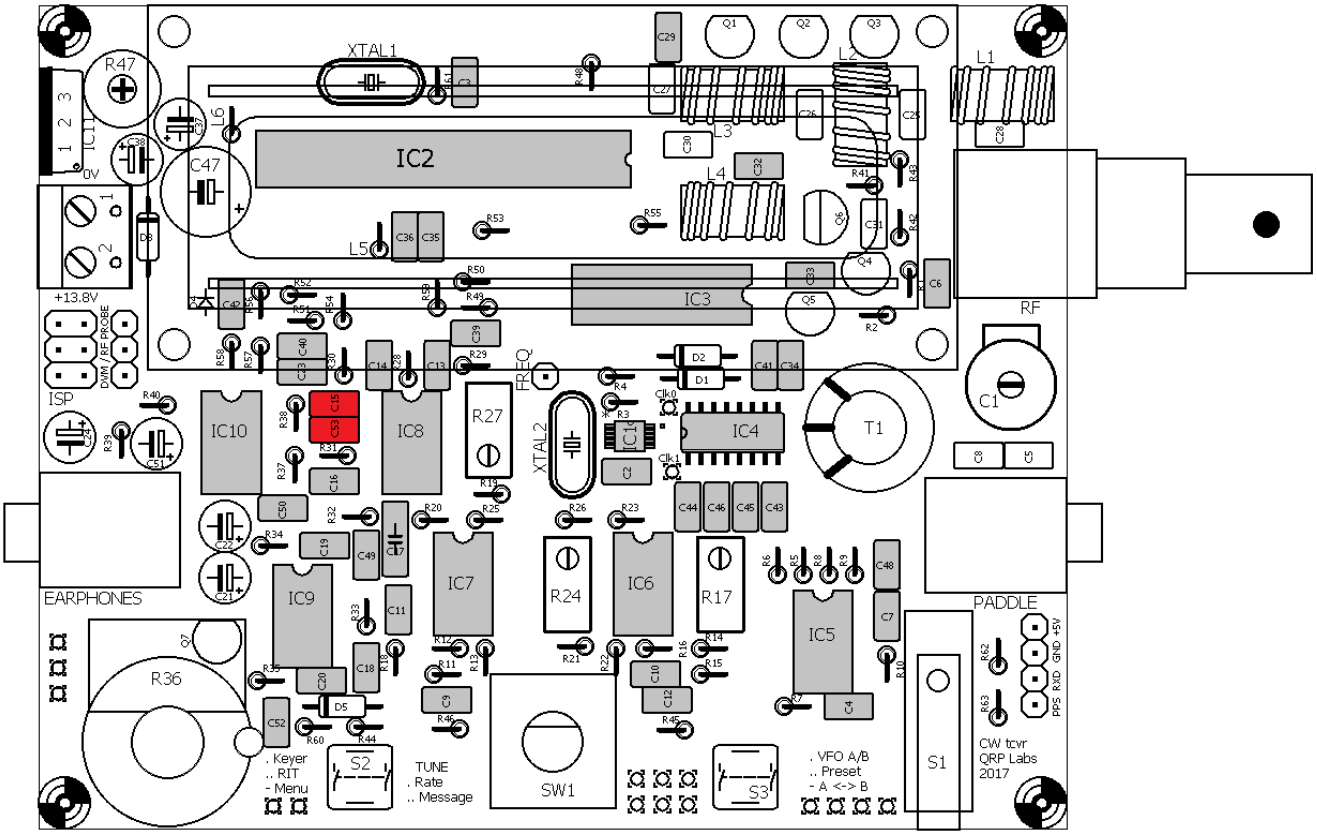
3.10 Install 2.2nF, “222” capacitors

The 2.2nF capacitors are labelled “222” and are C19 and C20.



3.11 Install 33nF, “333” and 3.3nF, “332” capacitors

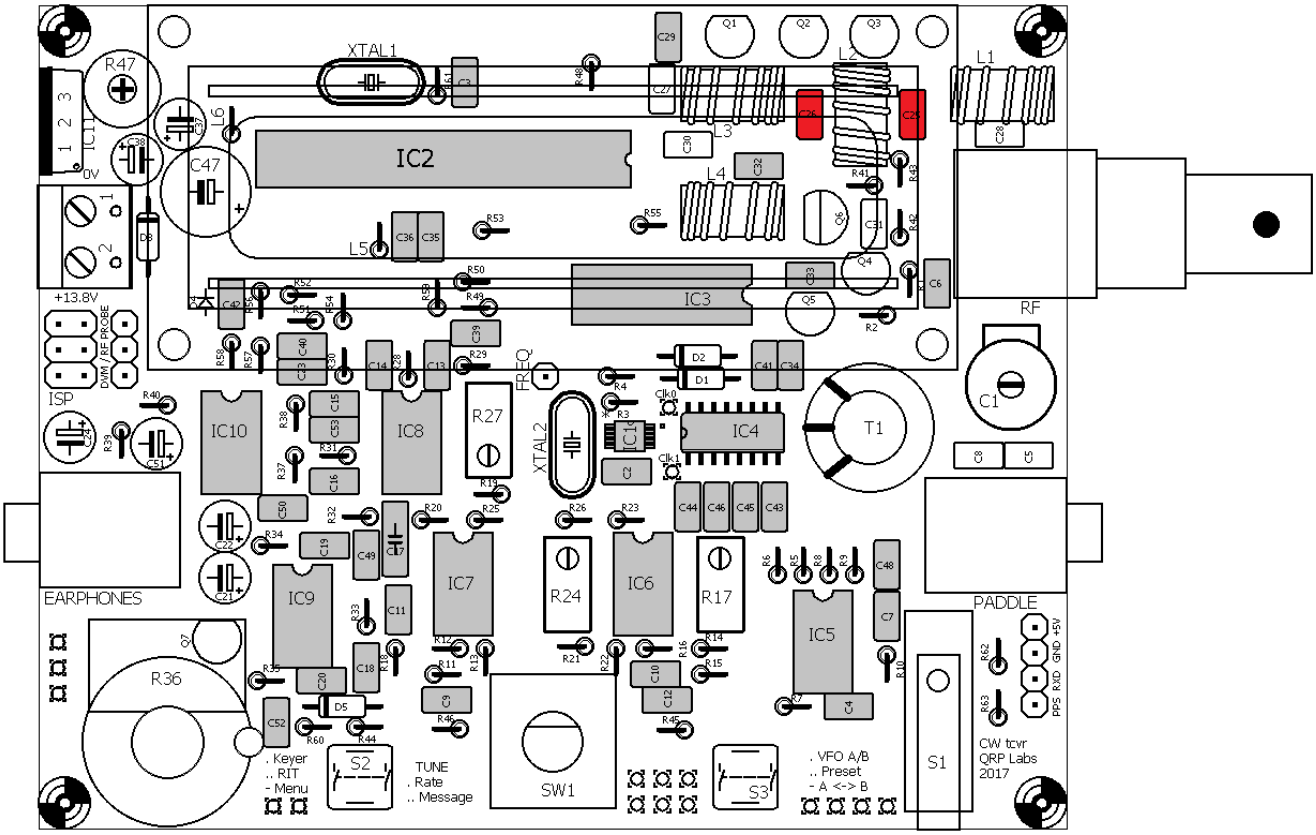
These are labelled “333” and “332”, and in parallel make up 36nF. They are C15 and C53.



3.12 Install capacitors C25 and C26 from the Low Pass Filter kit

The value of these capacitors depends on your chosen band. The capacitors are located inside the separate Low Pass Filter bag in your main kit bag. Refer to the following table to find the correct capacitor value for your band:

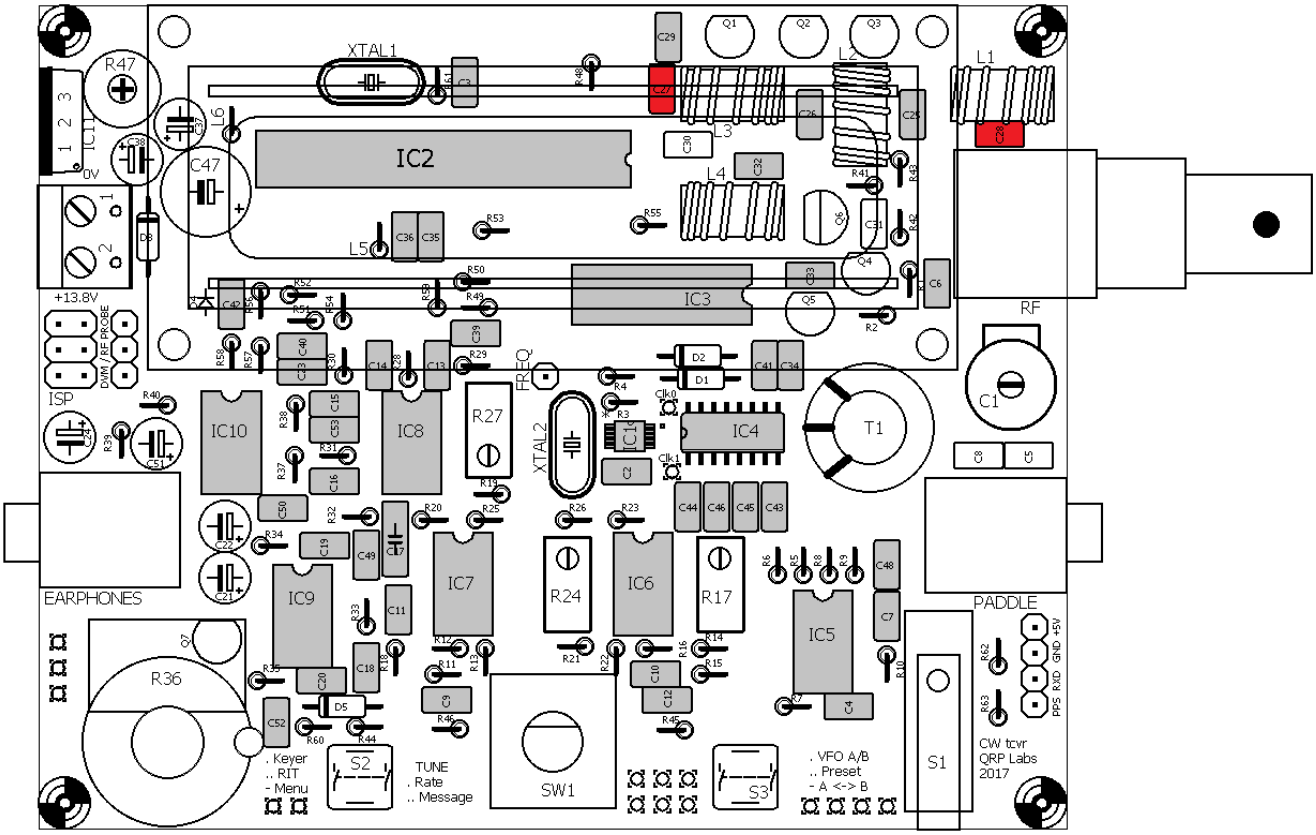
Band	Value	Label
80m	1200pF	“122”
60m	1200pF	“122”
40m	680pF	“681”
30m	560pF	“561”
20m	390pF	“391”
17m	270pF	“271”



3.13 Install capacitors C27 and C28 from the Low Pass Filter kit

The value of these capacitors depends on your chosen bandThe capacitors are located inside the separate Low Pass Filter bag in your main kit bag. Refer to the following table to find the correct capacitor value for your band:

Band	Value	Label
80m	470pF	“471”
60m	680pF	“681”
40m	270pF	“271”
30m	270pF	“271”
20m	180pF	“181”
17m	100pF	“101”



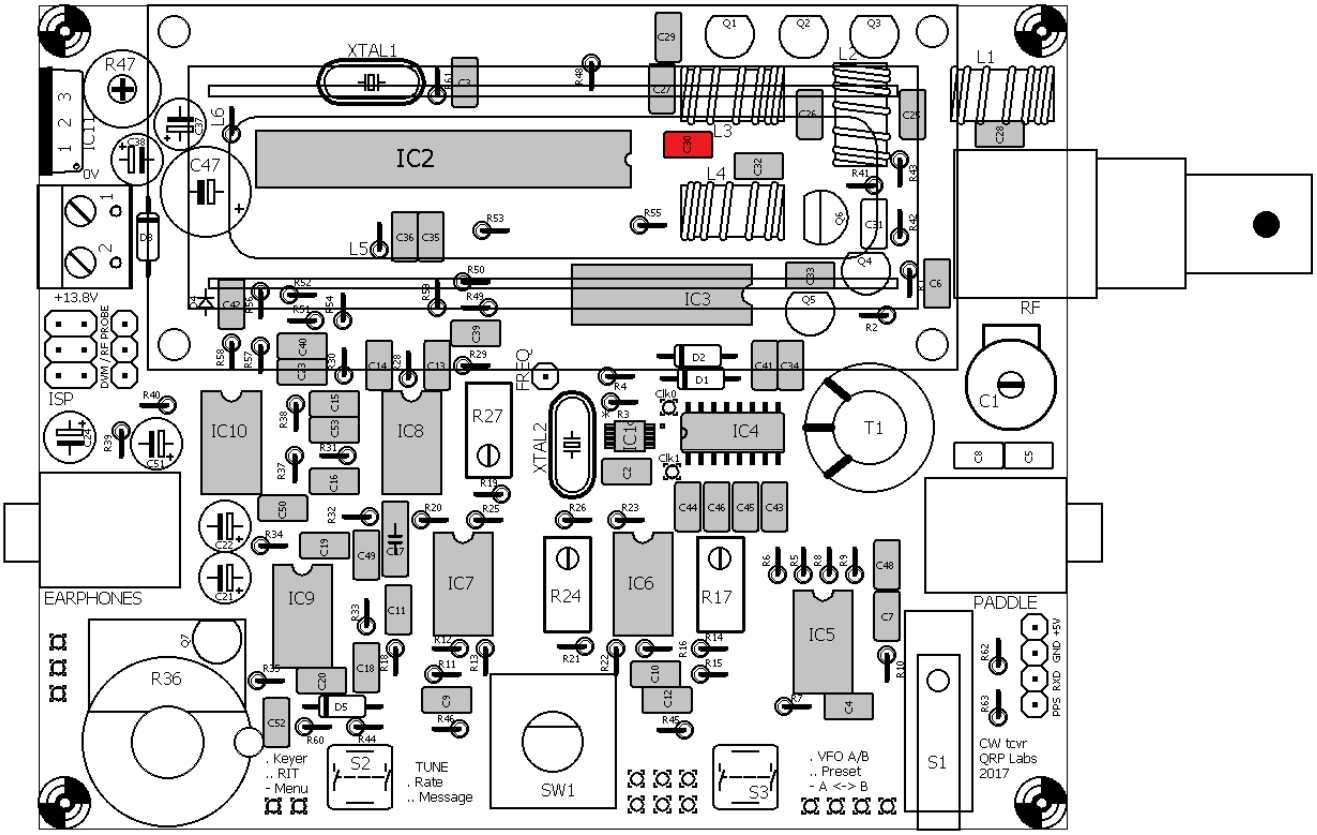
3.14 Install capacitor C30

This capacitor is band dependent. The kit contains all required capacitor values for all bands. Install the one appropriate to your band. Refer to the following table to find the correct capacitor value for your band:

Band	Value	Label
80m	180pF	“181”
60m	30pF 56pF	“300” “560”
40m	56pF	“560”
30m	30pF	“300”
20m	30pF	“300”
17m	30pF	“300”

60m important note: for the 60m band, the capacitor requires both the 30pF and 56pF capacitors to be soldered in parallel, but there is only one component position on the PCB. For 60m, you will need to install one of the capacitors (e.g. 56pF) in the component holes provided, and solder the other one (e.g. 30pF) to the same pads under the PCB. Take care to keep the component wires short and not accidentally touching any other nearby components or soldered pads.

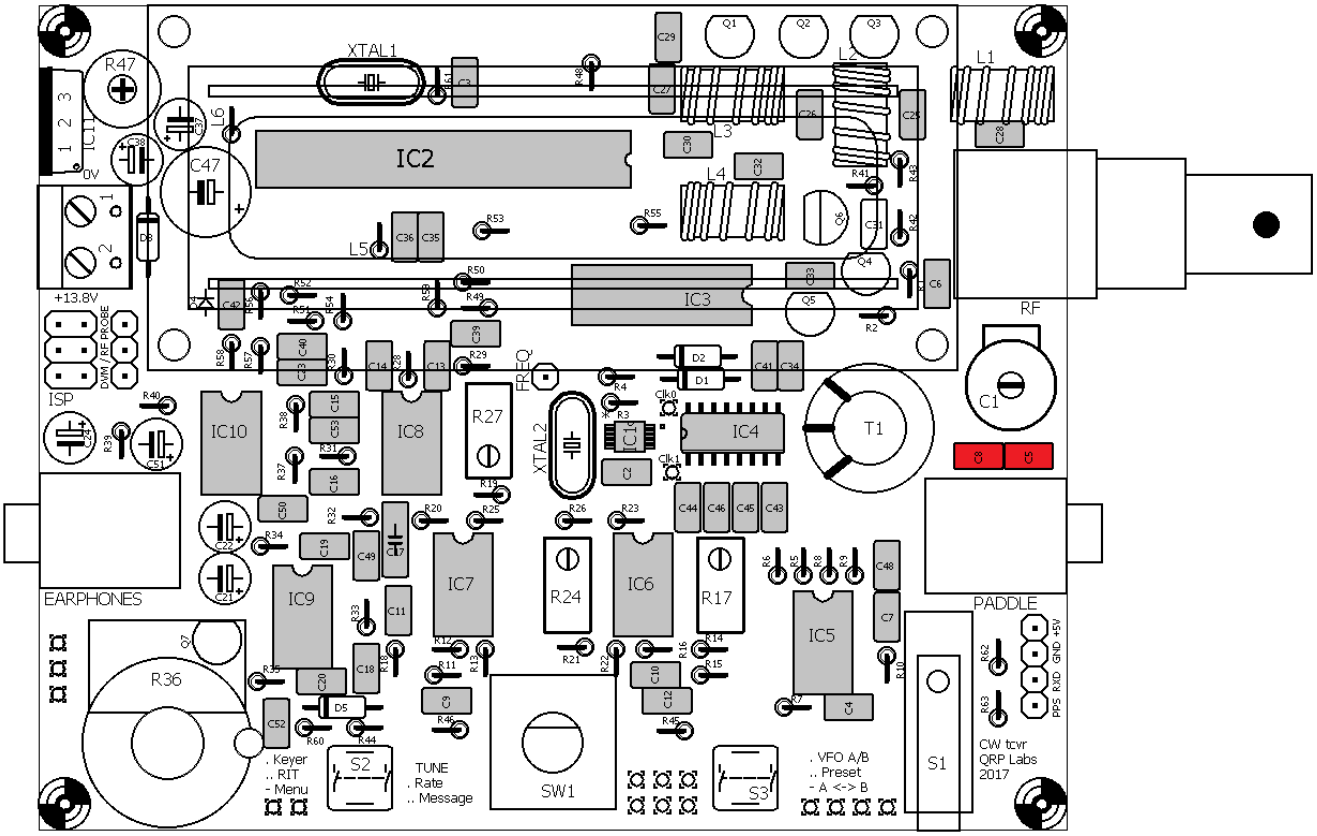
80m important note: the 180pF capacitor supplied has a 0.2-inch (5.08mm) pin spacing. But the holes on the PCB are spaced 0.1-inch (2.5mm). It is necessary to squeeze the capacitors wires carefully closer together to fit the PCB holes.



3.15 Install capacitors C5 and C8

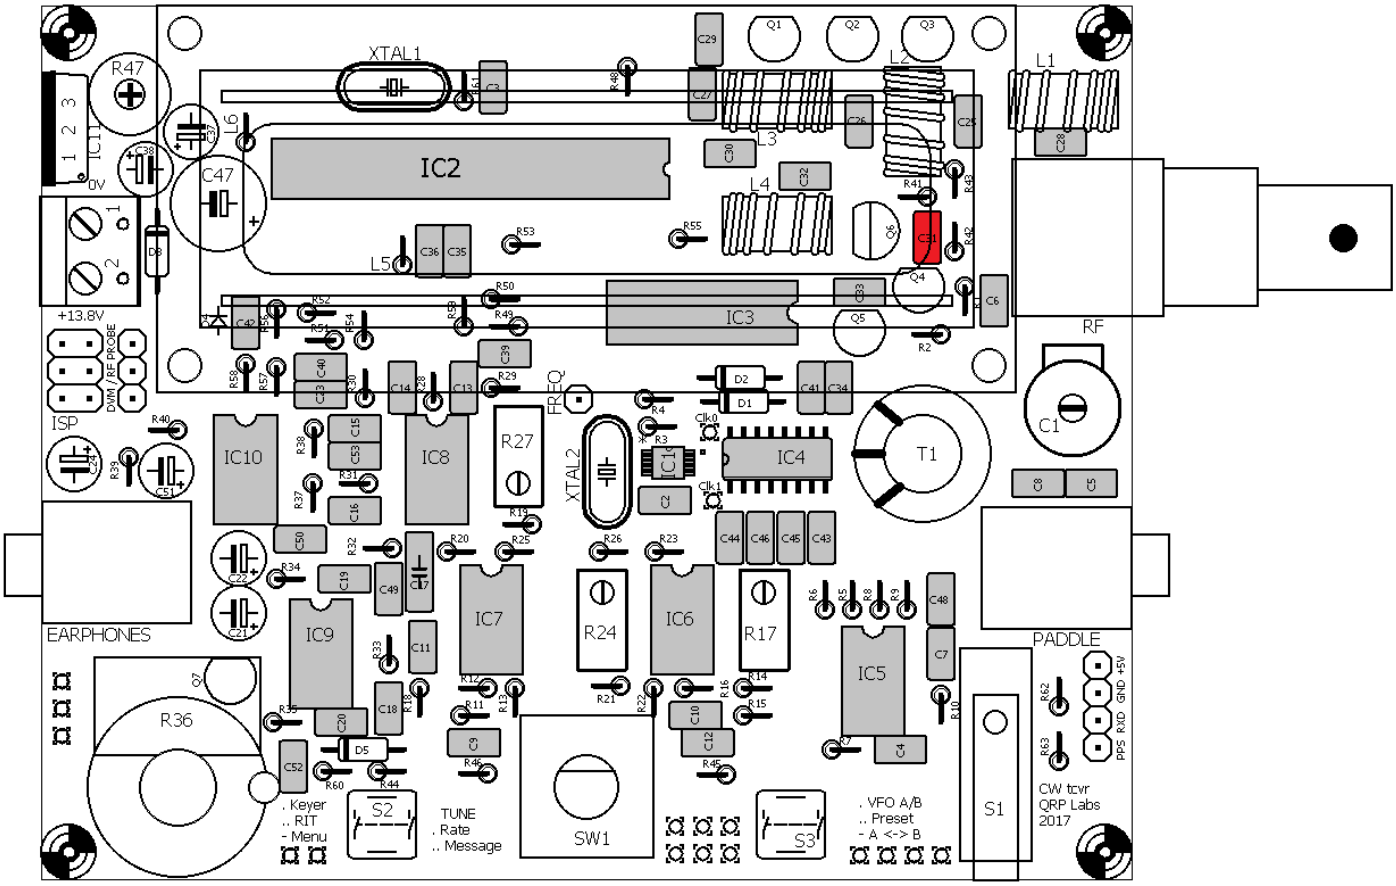
These capacitors are band dependent. They add parallel capacitance to trimmer capacitor C1 to bring it to the required value. The kit contains all required capacitor values. Install the capacitor(s) appropriate to your band. Refer to the following table to find the correct capacitor value(s) for your band. Where “none” is indicated in the table, do not install the corresponding capacitor.

Band	C5 Value	C5 Label	C8 value	C8 Label
80m	39pF	“390”	22pF	“220”
60m	39pF	“390”	22pF	“220”
40m	39pF	“390”	none	
30m	22pF	“220”	none	
20m	none		none	
17m	none		none	



3.16 Install 1uF, “105” capacitor

The 1uF capacitor is labelled “105” and is C31.

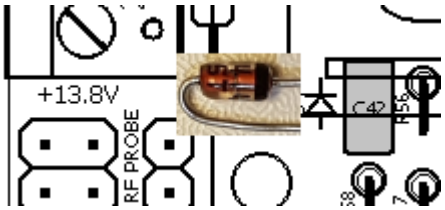


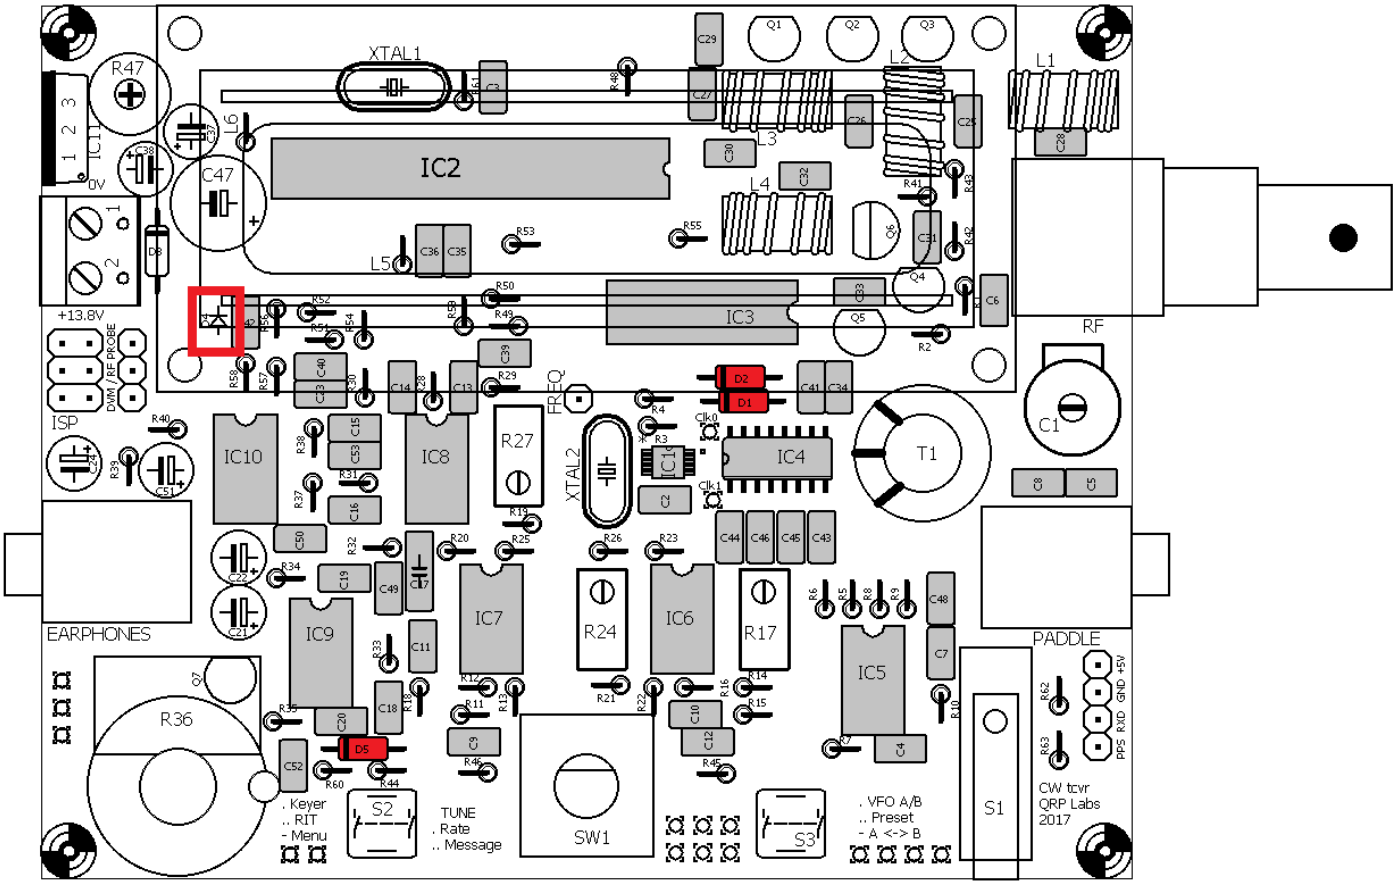
3.17 Install 1N4148 diodes

There are 4 small glass red-ish coloured diodes, D1, D2, D4 and D5. Note that D1, D2 and D5 are installed flat on the PCB (see photo, right). D4 is installed vertically, (see photo, far right).

In all cases it is critical to install the diodes the right way around, these are a polarised component and must only be installed in the PCB with the correct orientation! In the case of D1, D2 and D5, the PCB silkscreen printing shows a white stripe at the end of the diode body which must match the black stripe on the left end of the diode (photo above).

For D4, the black stripe on the diode body must be orientated with the horizontal bar of the diode symbol on the layout diagram (see photo, right). D4 is mounted vertically. The location of D4 is indicated by the red square, near the top left of the diagram on the following page.



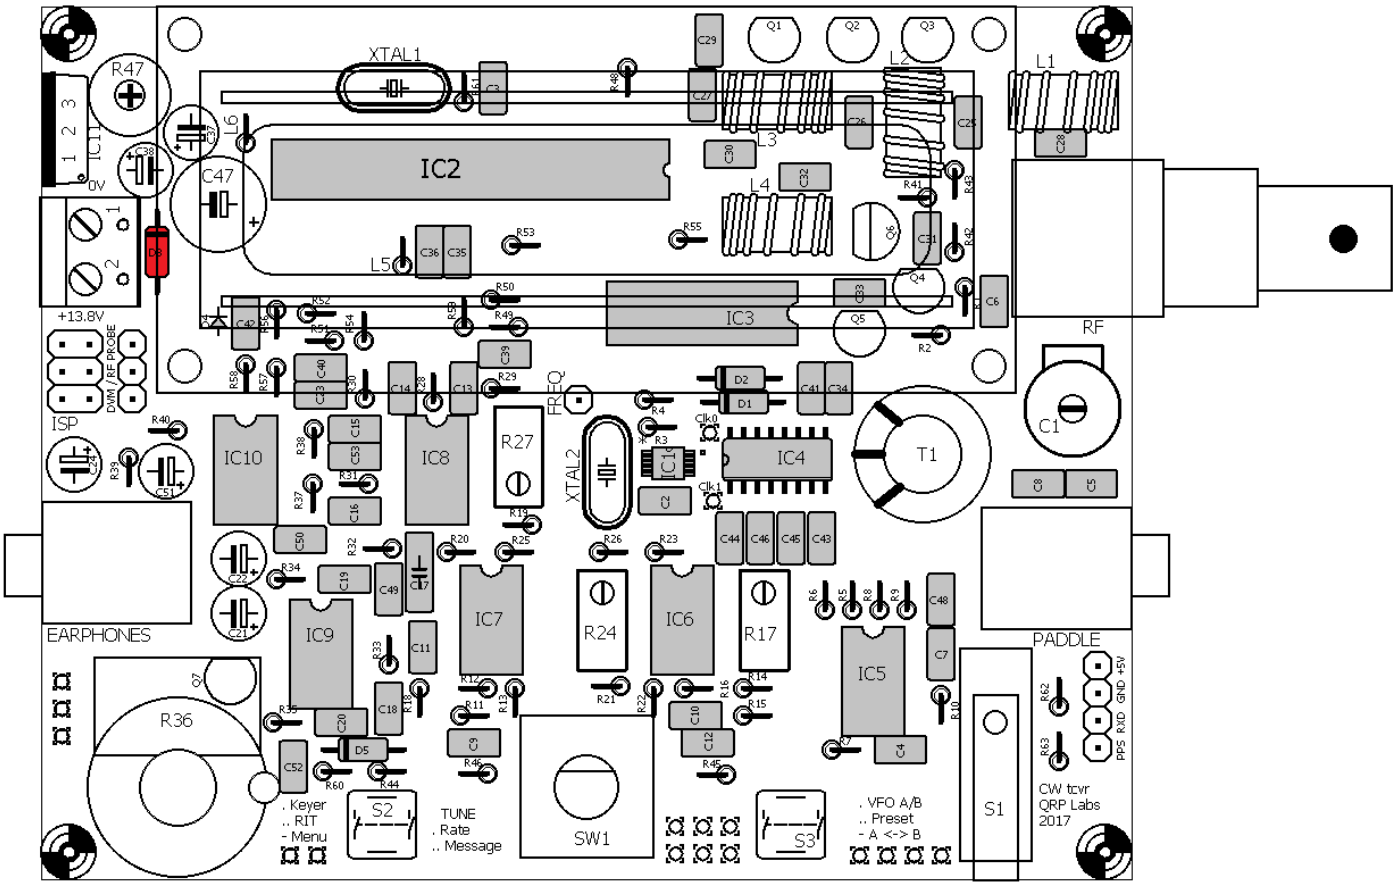


3.18 Install 1N5819 diode

This diode D3 is the larger diode with a black body, and a white stripe. It is installed horizontally. Again, it must be orientated correctly, with the white stripe on the diode matching the white stripe on the PCB.

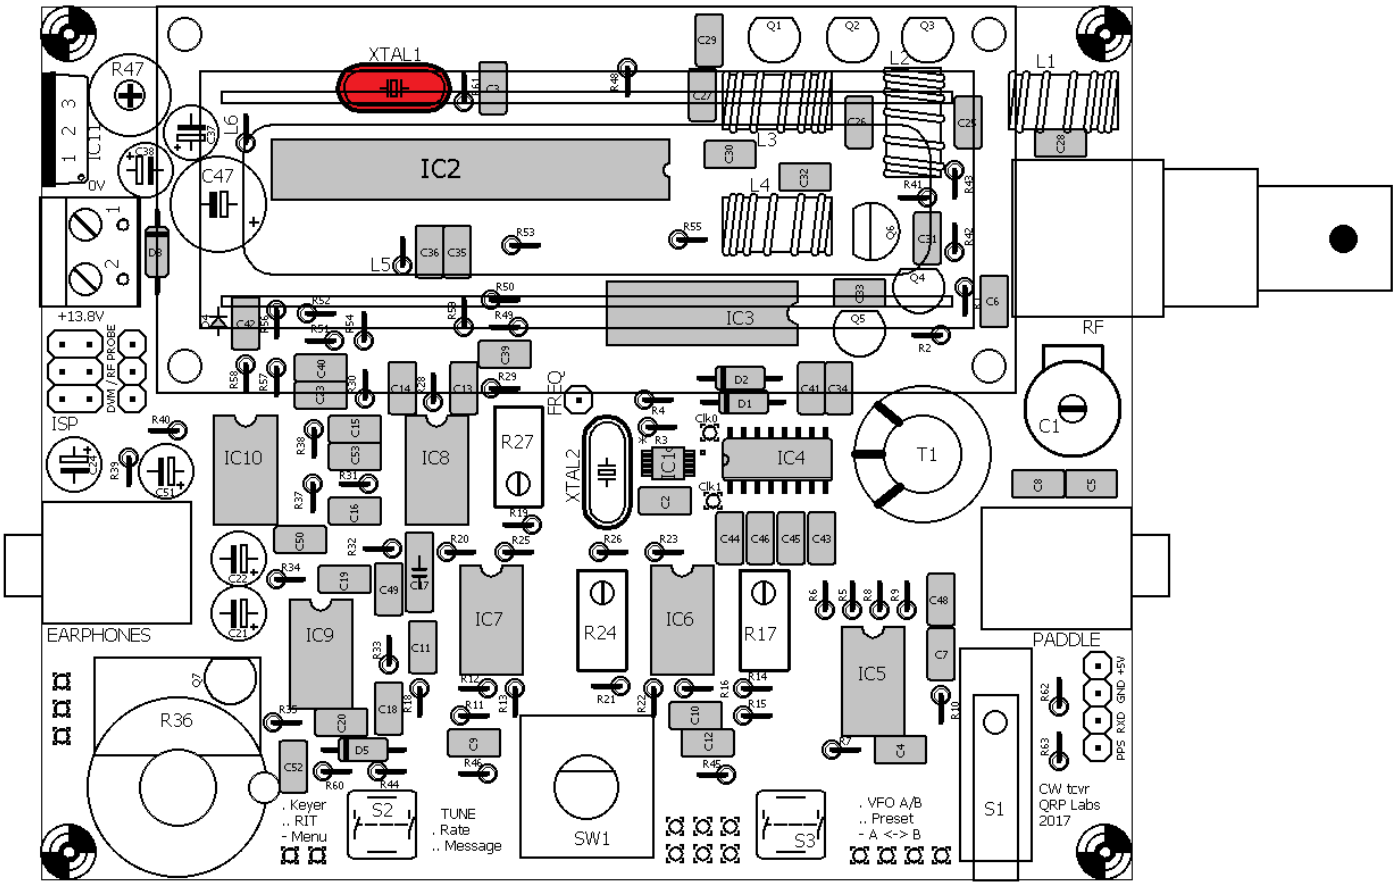
This diode protects the radio against reverse polarity. So that if you connect the power to the board the wrong way around, you do not destroy it. A Schottky diode is used because the forward conducting voltage drop is less than an ordinary diode. However, on transmit, the voltage drop across this diode can still be up to 400mV. This reduction in voltage does slightly decrease the output power.

IF you want to squeeze every last milliwatt of output power out of the radio, and IF you trust yourself NEVER to connect the power supply in reverse by mistake, then if you just install a jumper wire instead of D3, it would give you a little higher RF power output.



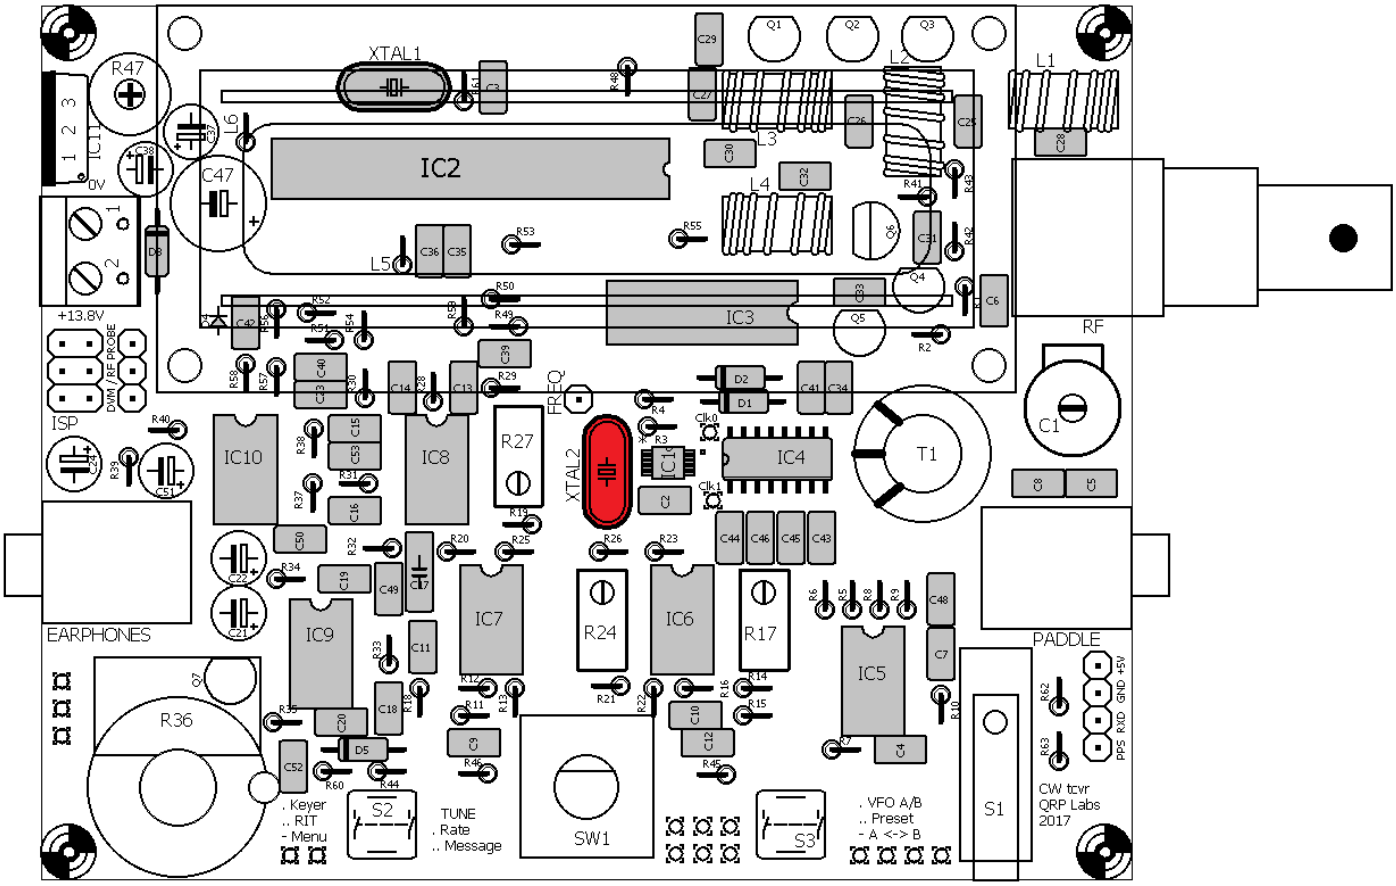
3.19 Install 20MHz crystal XTAL1

The engraving on this crystal is “20.000”.



3.20 Install 27MHz crystal XTAL2

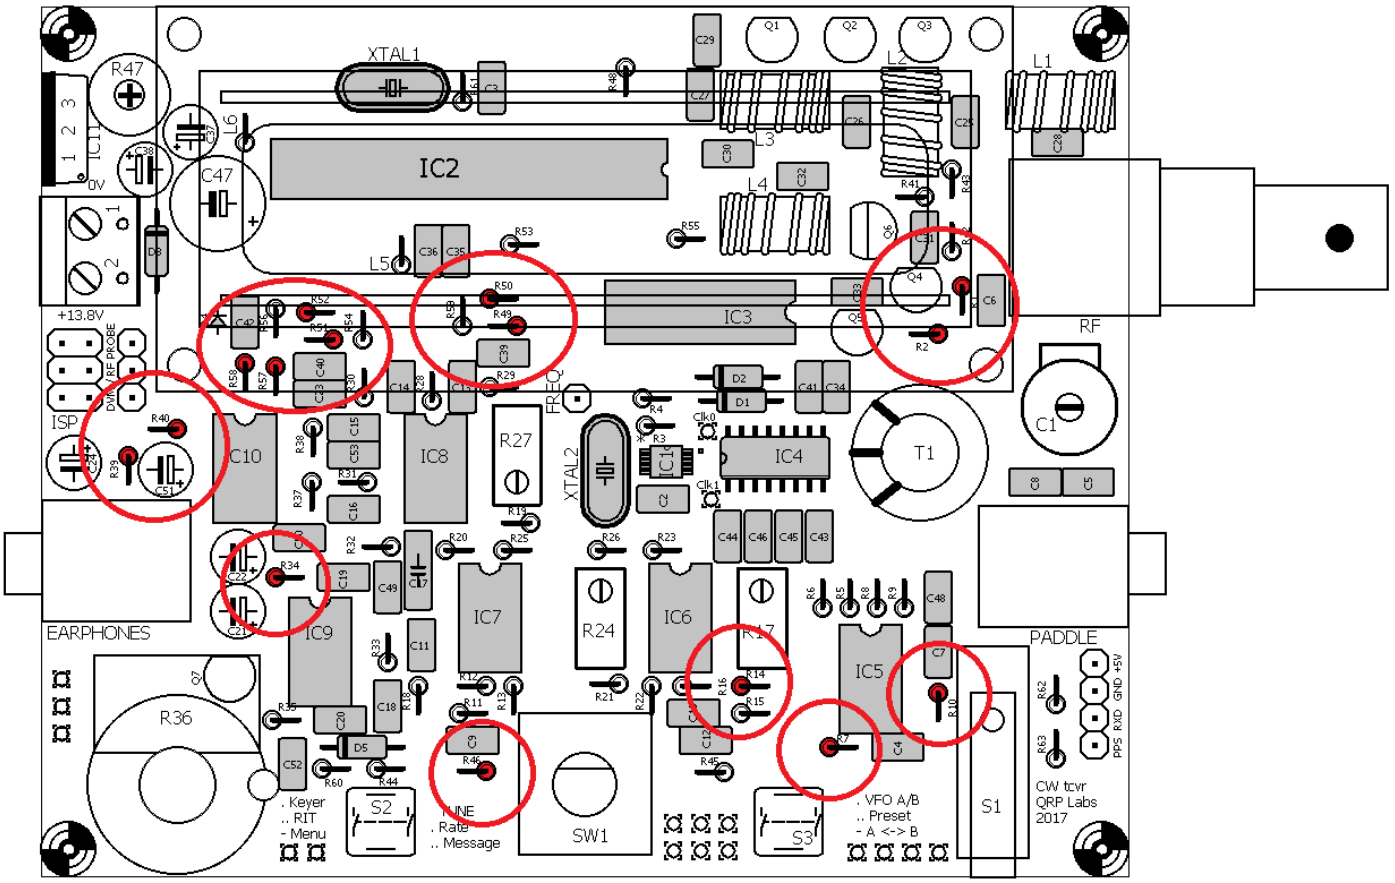
The engraving on this crystal is “27.000”.



3.21 Install all 10K resistors

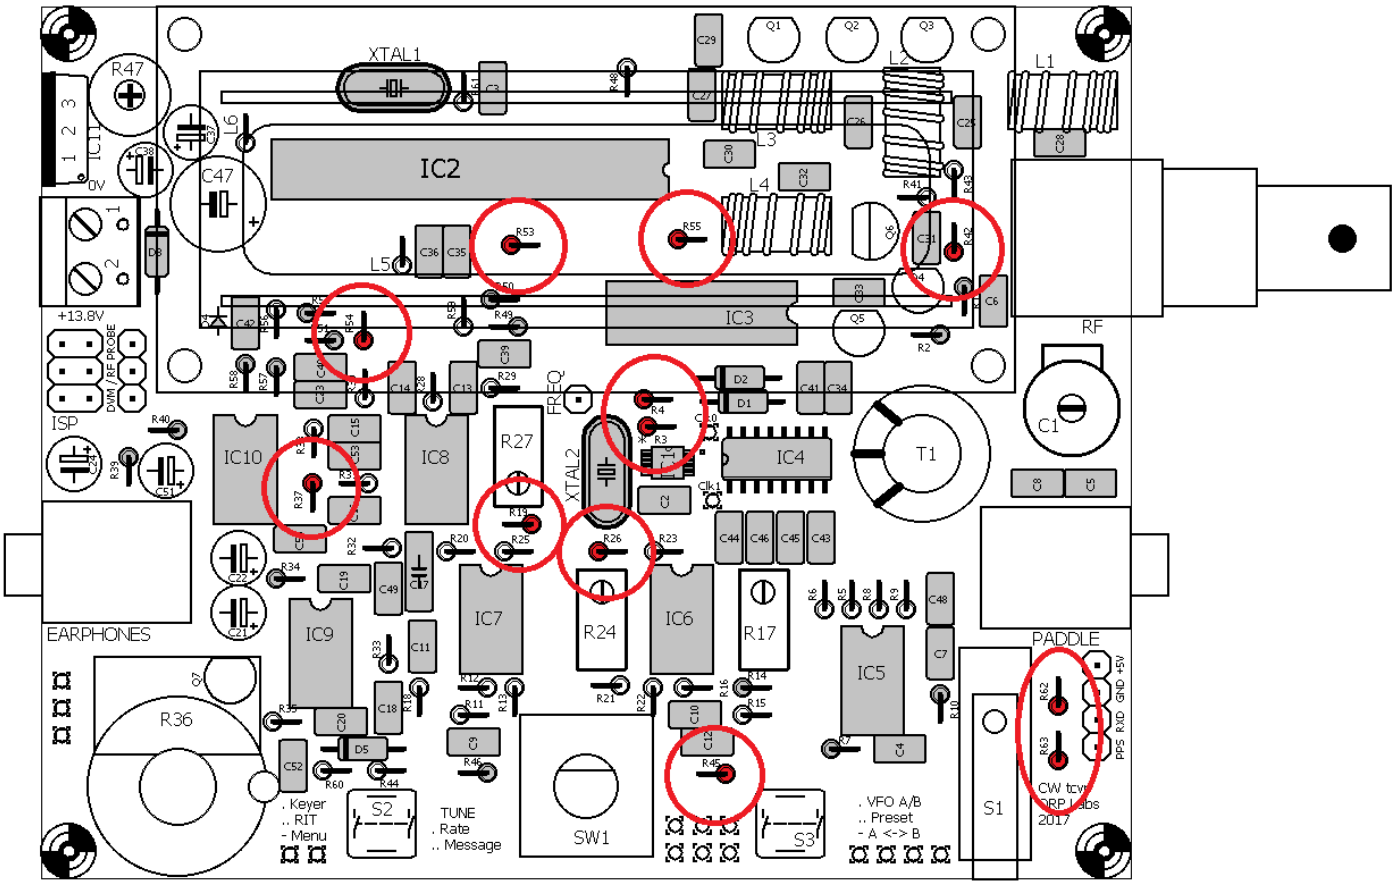
There are 15 10K resistors in the kit, these are R1, R2, R7, R10, R14, R34, R39, R40, R46, R49, R50, R51, R52, R57 and R58. The colour code is brown-black-black-red-brown. All of the resistors in the kit are installed vertically (see photo, right).

Resistors are not polarised components and it does not matter which way around they are installed. For simplicity I recommend installing the body end of the resistor next to the circle on the PCB silkscreen (and the layout diagrams).



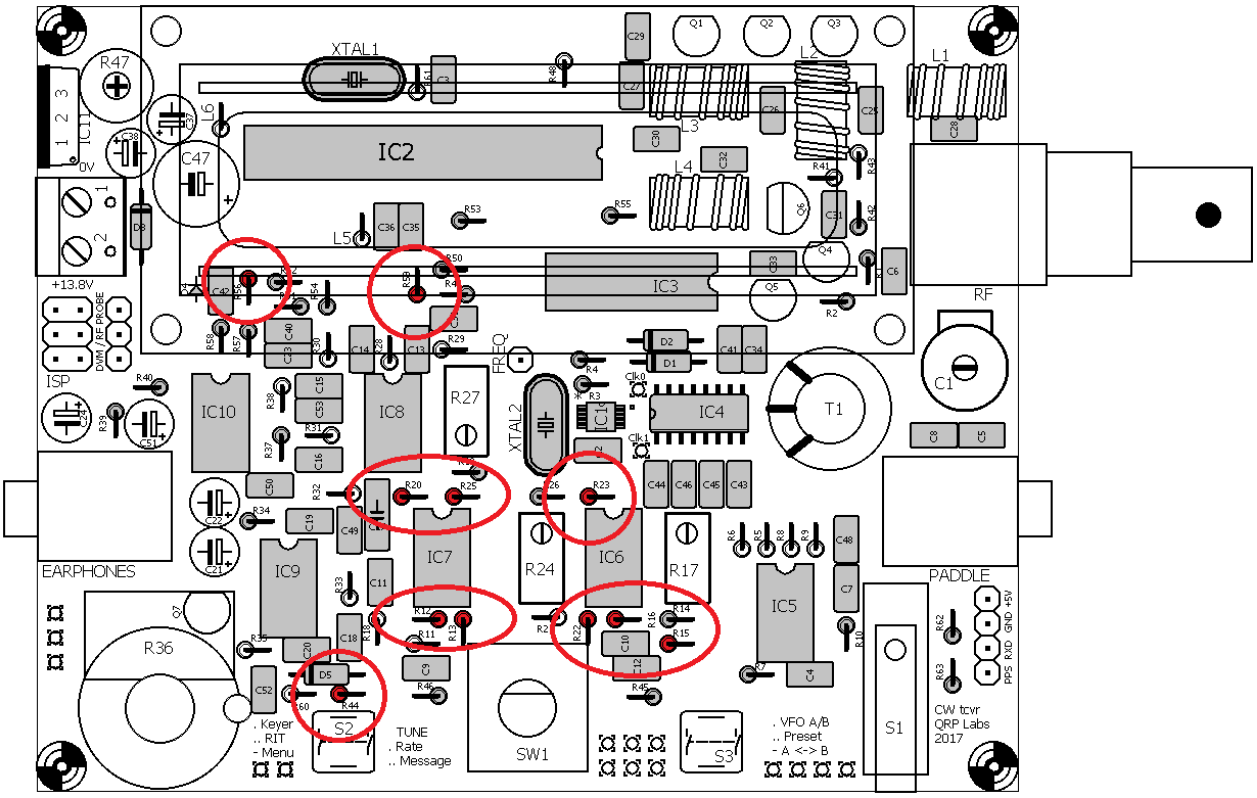
3.22 Install all 1K resistors

There are 12 1K resistors in the kit, these are R3, R4, R19, R26, R37, R42, R45, R53, R54, R55, R62 and R63. The colour code is brown-black-black-brown-brown.



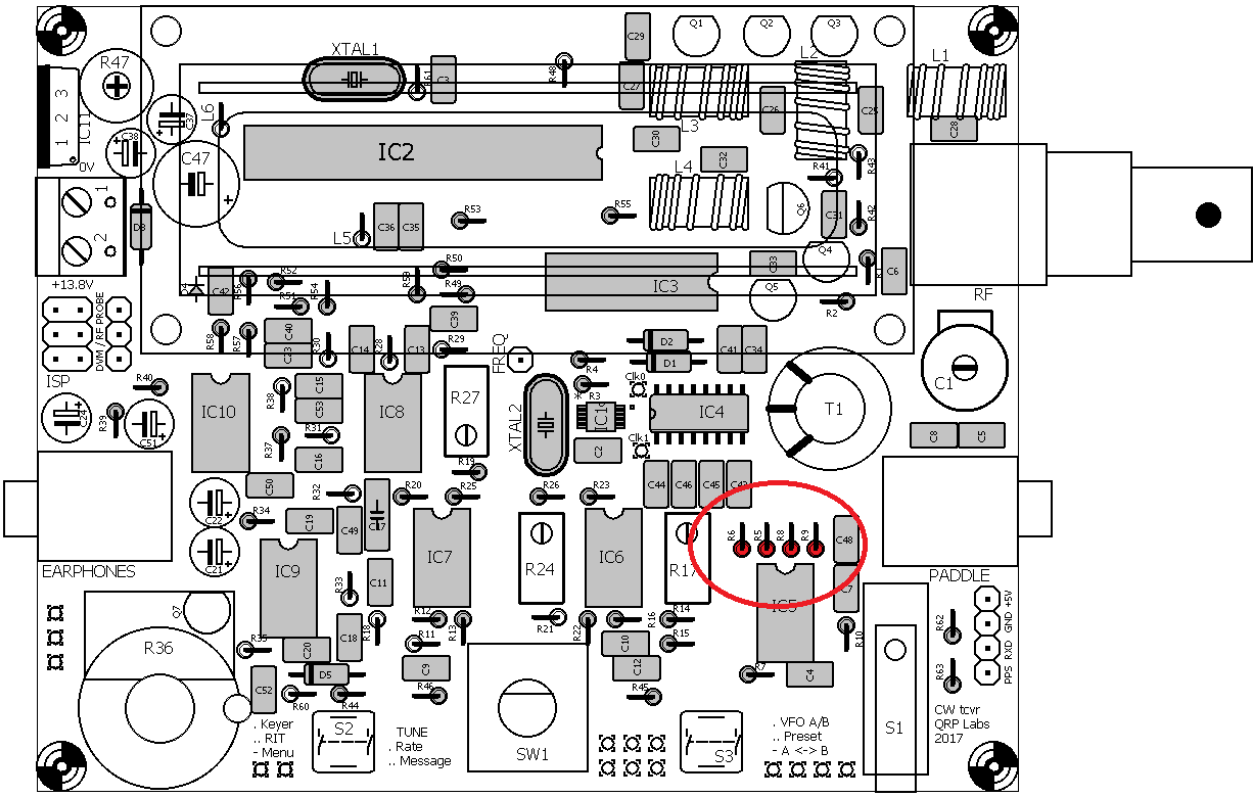
3.23 Install all 3.3K resistors

There are 11 3.3K resistors in the kit, these are R12, R13, R15, R16, R20, R22, R23, R25, R44, R56 and R59. The colour code is orange-orange-black-brown-brown.



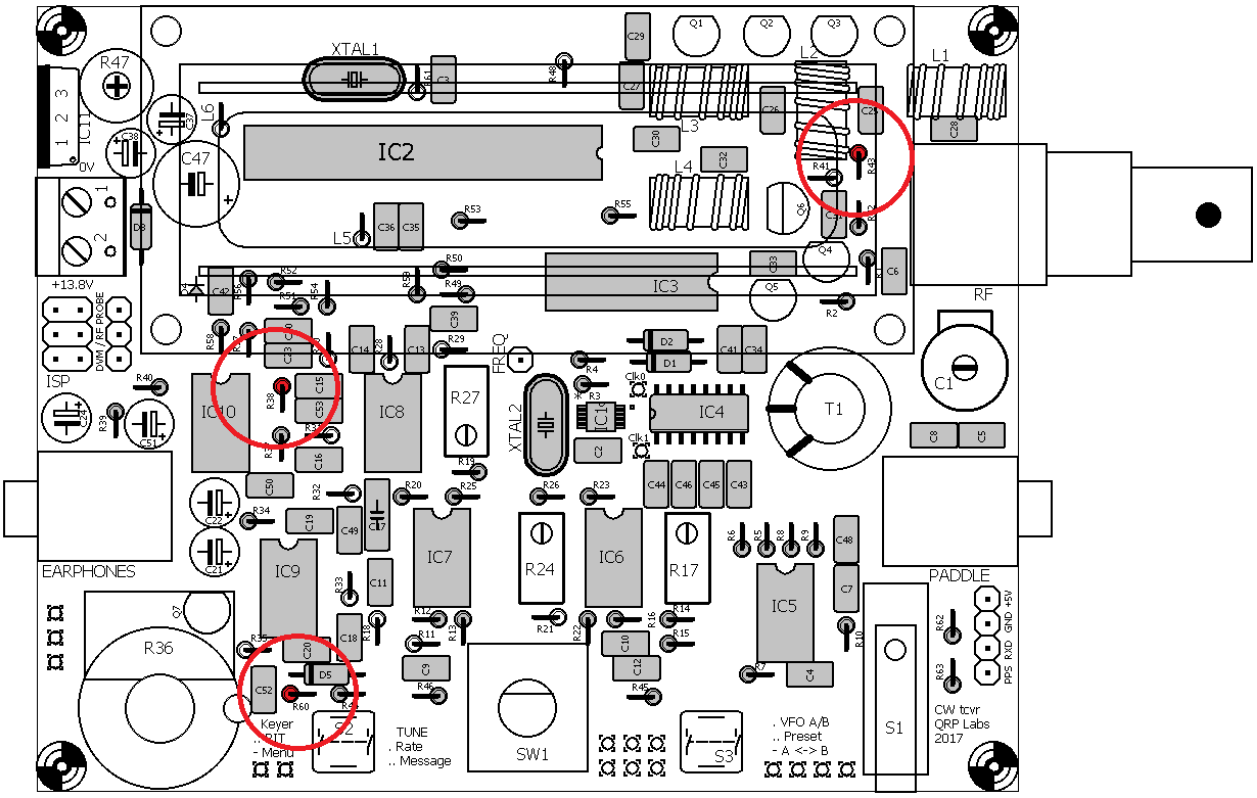
3.24 Install all 100-ohm resistors

There are four 100-ohm resistors in the kit, these are R5, R6, R8 and R9. The colour code is brown-black-black-black-brown.



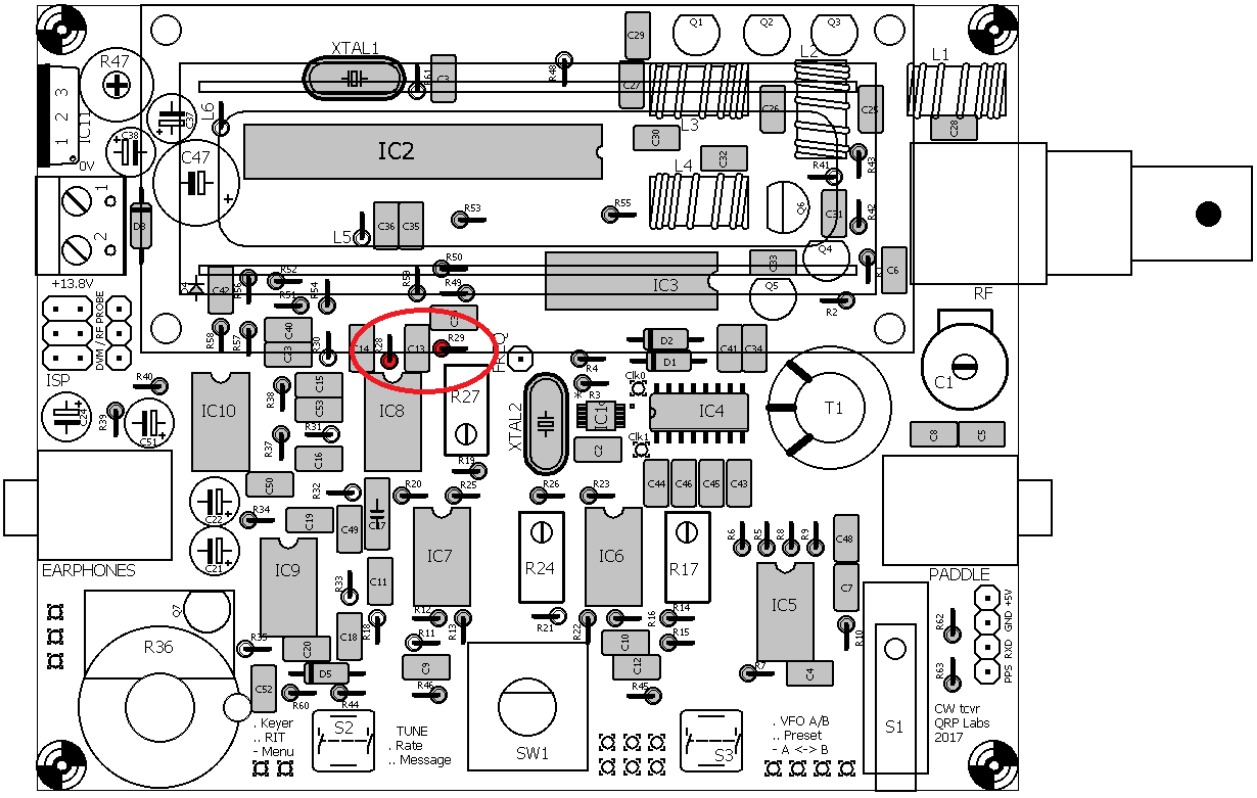
3.25 Install 120K resistors

There are three 120K resistors in the kit, these are R38, R43 and R60. The colour code is brown-red-black-orange-brown.



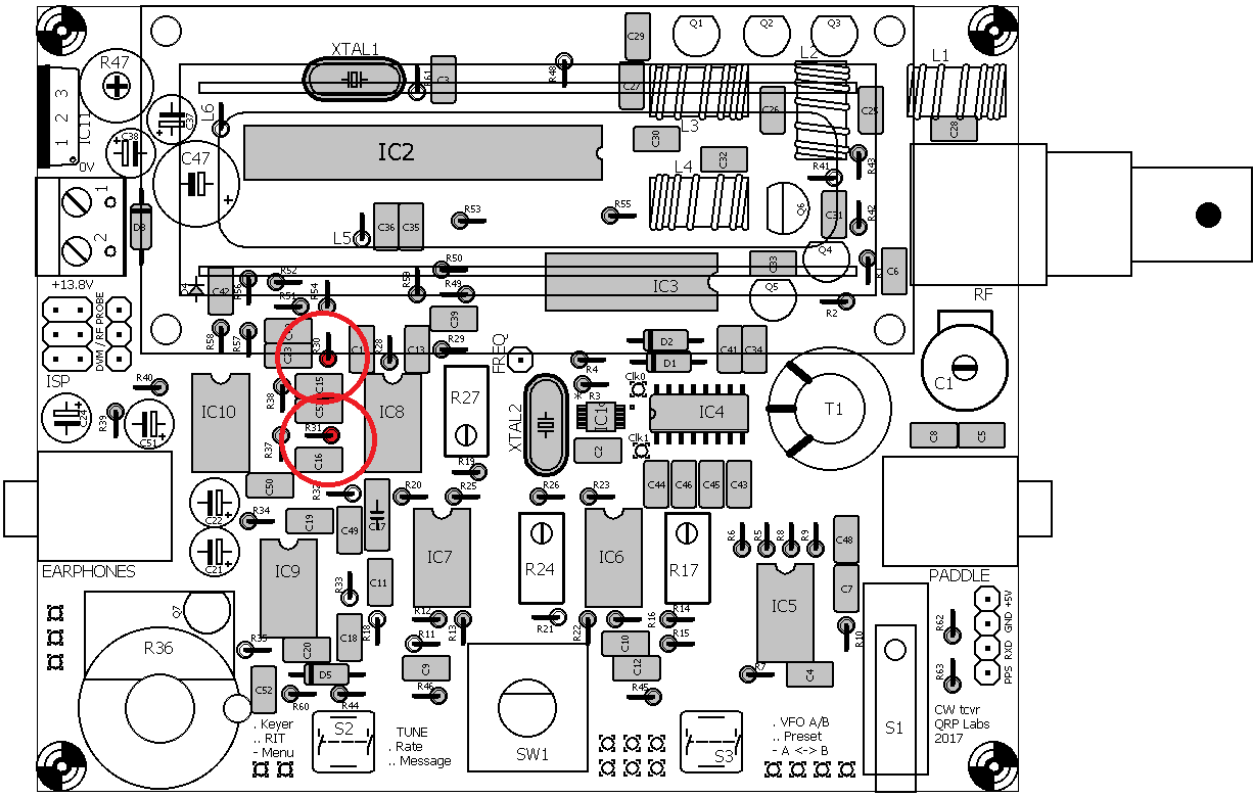
3.26 Install 33K resistors

There are two 33K resistors in the kit, these are R28 and R29. The colour code is orange-orange-black-red-brown.



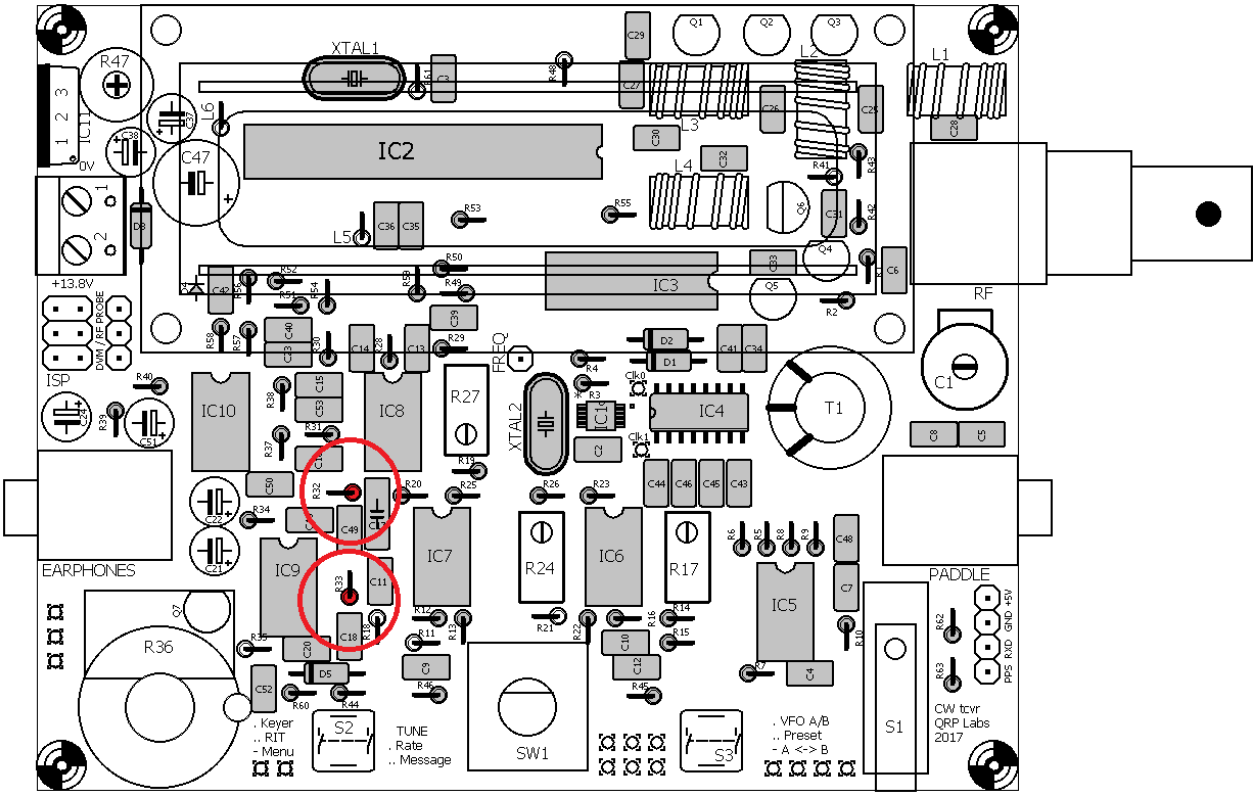
3.27 Install 47K resistors

There are two 47K resistors in the kit, these are R30 and R31. The colour code is yellow-purple-black-red-brown.



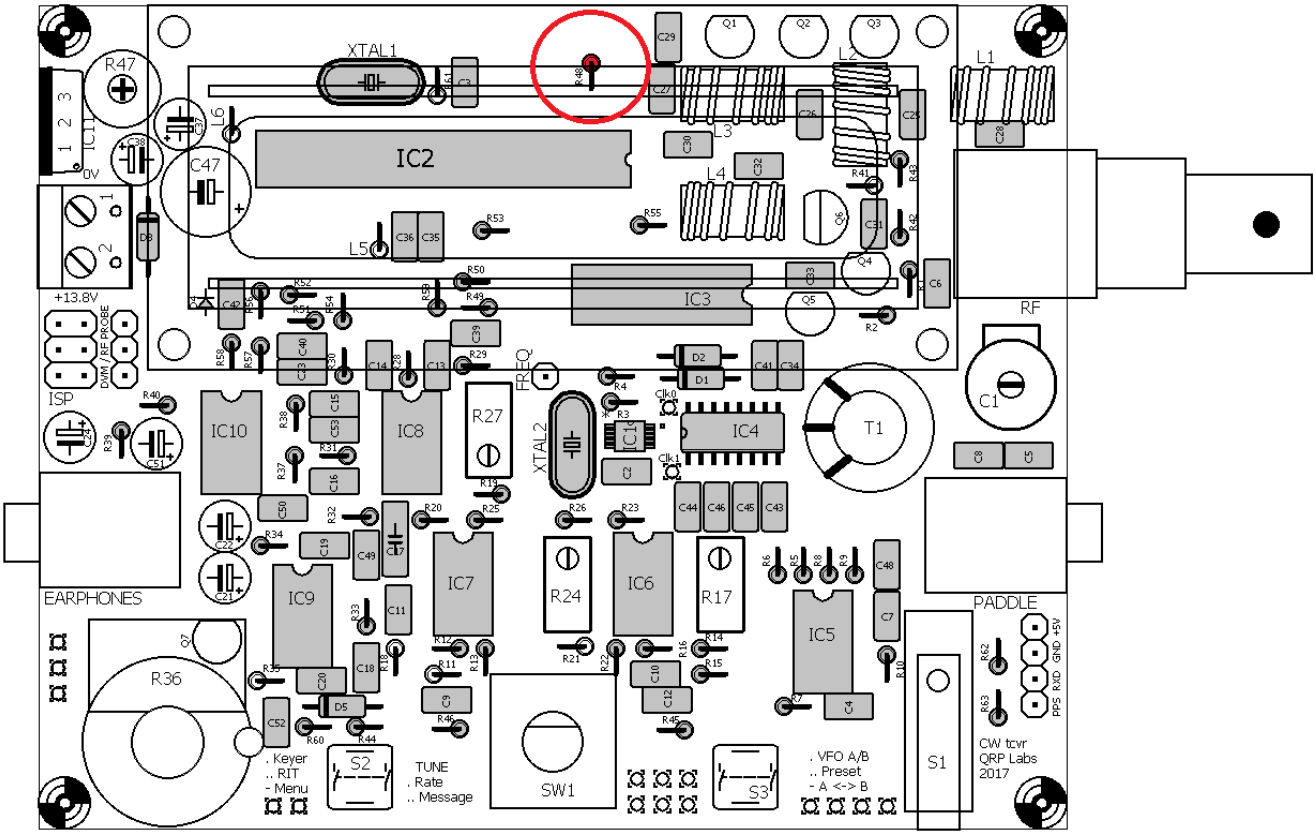
3.28 Install 36K resistors

There are two 36K resistors in the kit, these are R32 and R33. The colour code is orange-blue-black-red-brown.



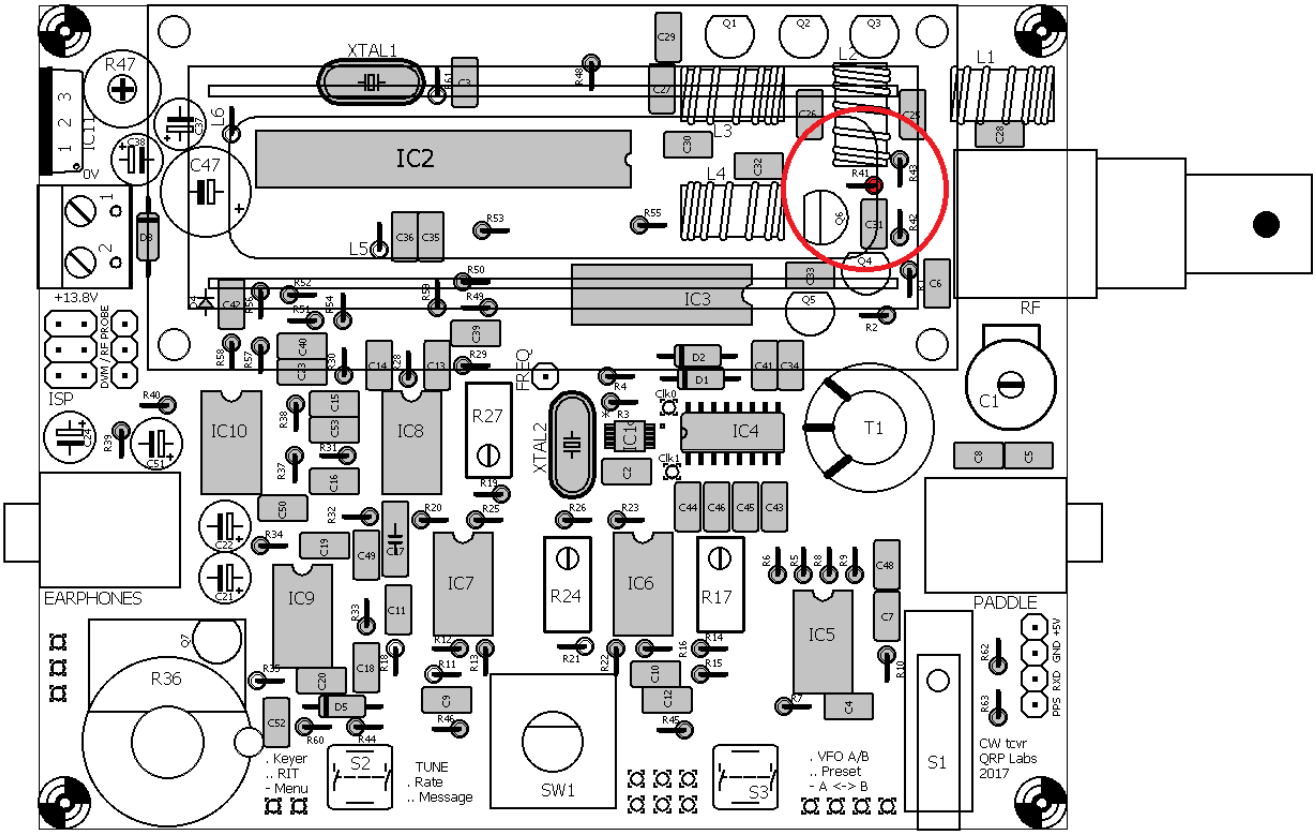
3.29 Install 270-ohm resistor R48

This resistor has colour code red-purple-black-black-brown.



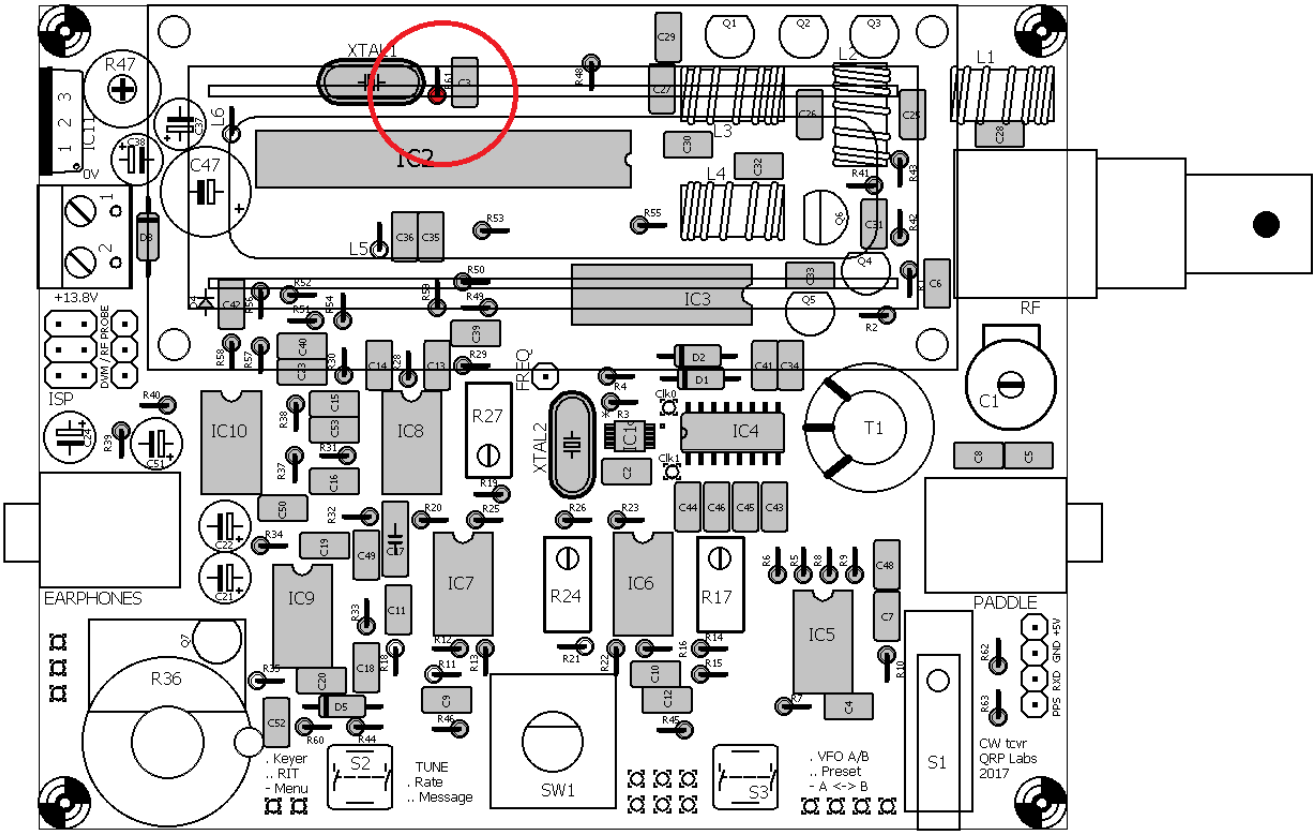
3.30 Install 470-ohm resistor R41

This resistor has colour code yellow-purple-black-black-brown.



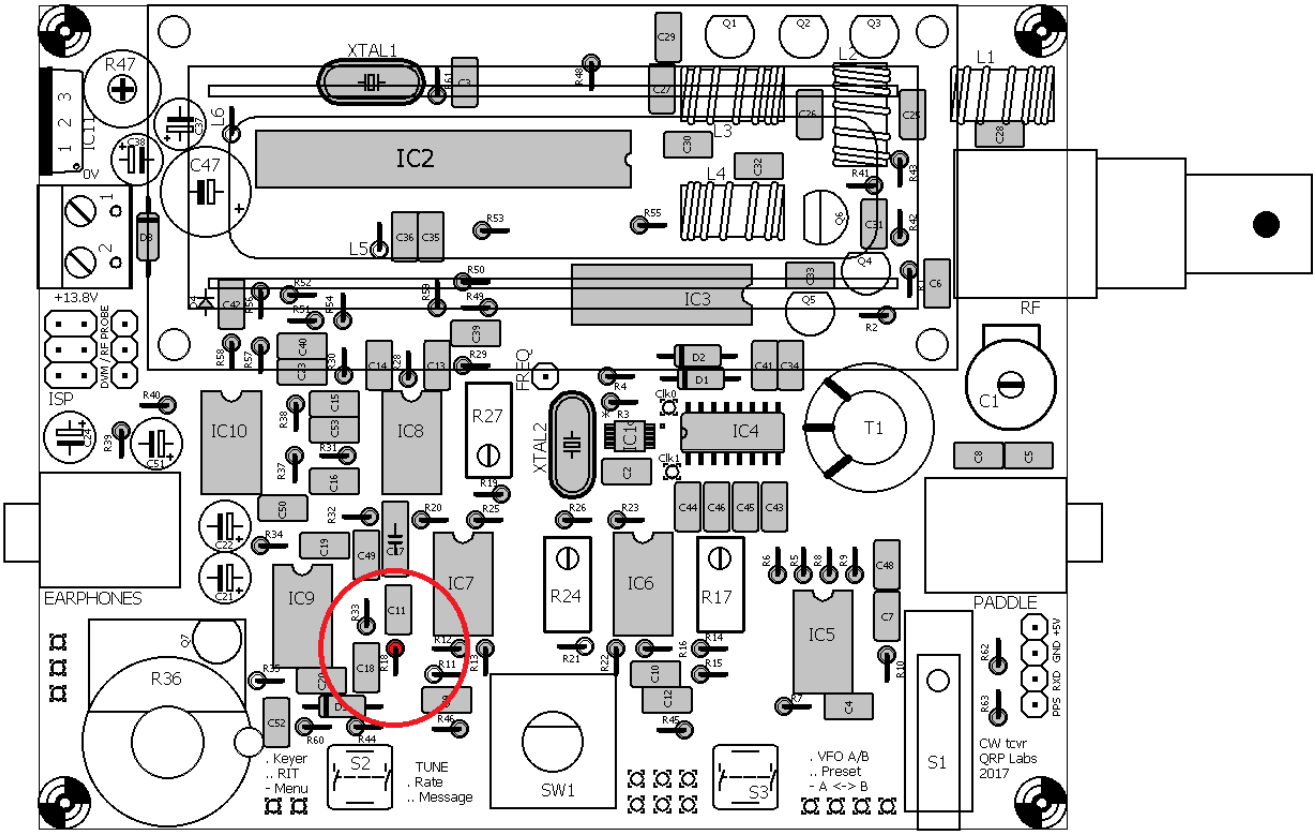
3.31 Install 3.9K resistor R61

This resistor has colour code orange-white-black-brown-brown.



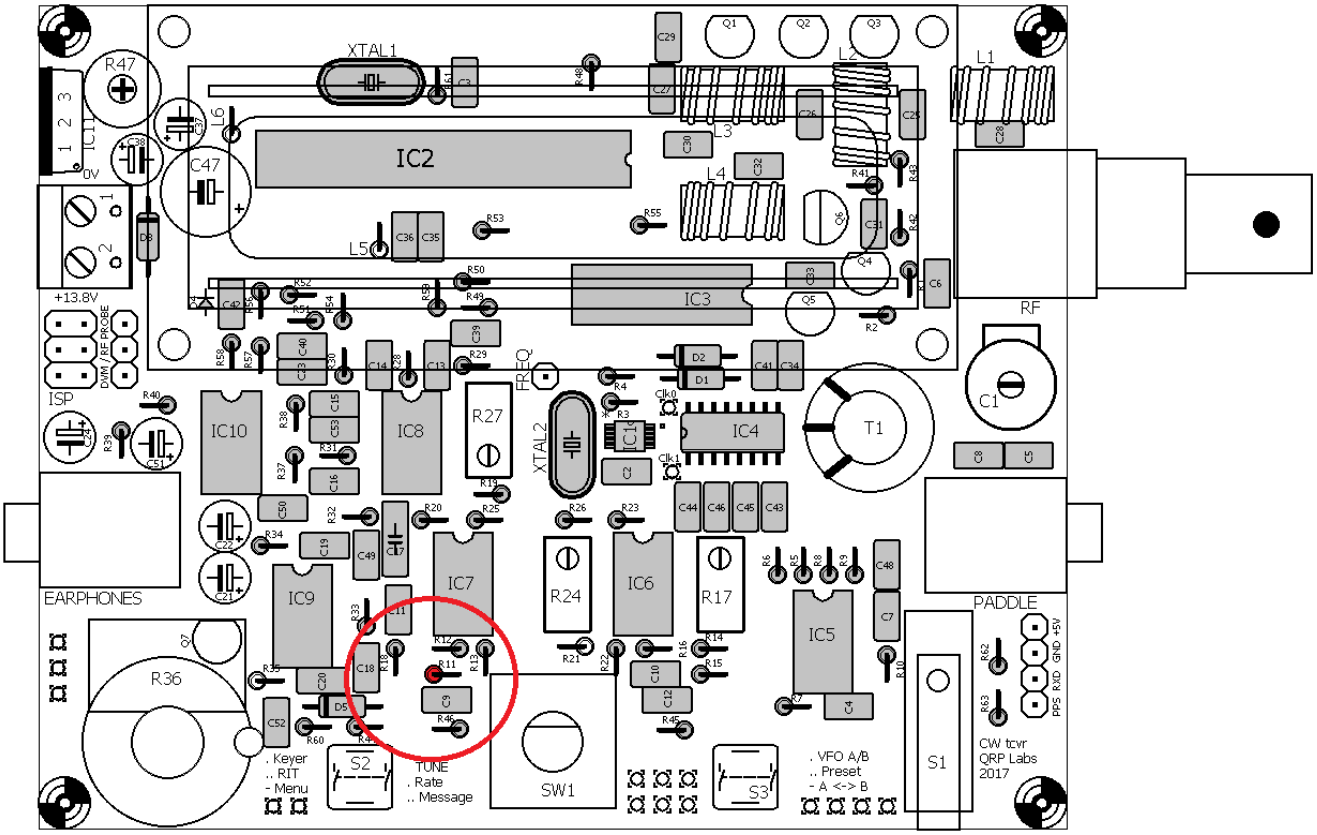
3.32 Install 4.3K resistor R18

This resistor has colour code yellow-orange-black-brown-brown.



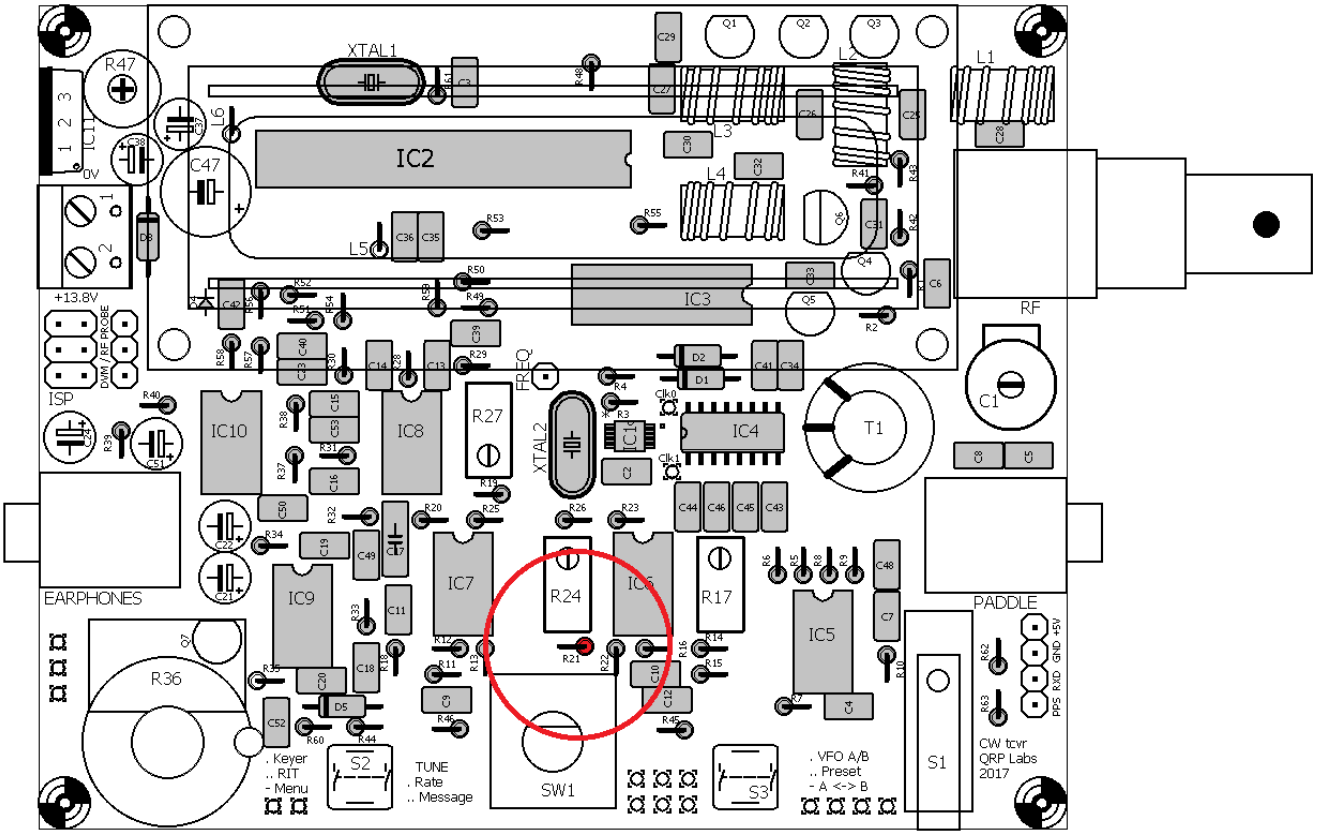
3.33 Install 5.1K resistor R11

This resistor has colour code green-brown-black-brown.



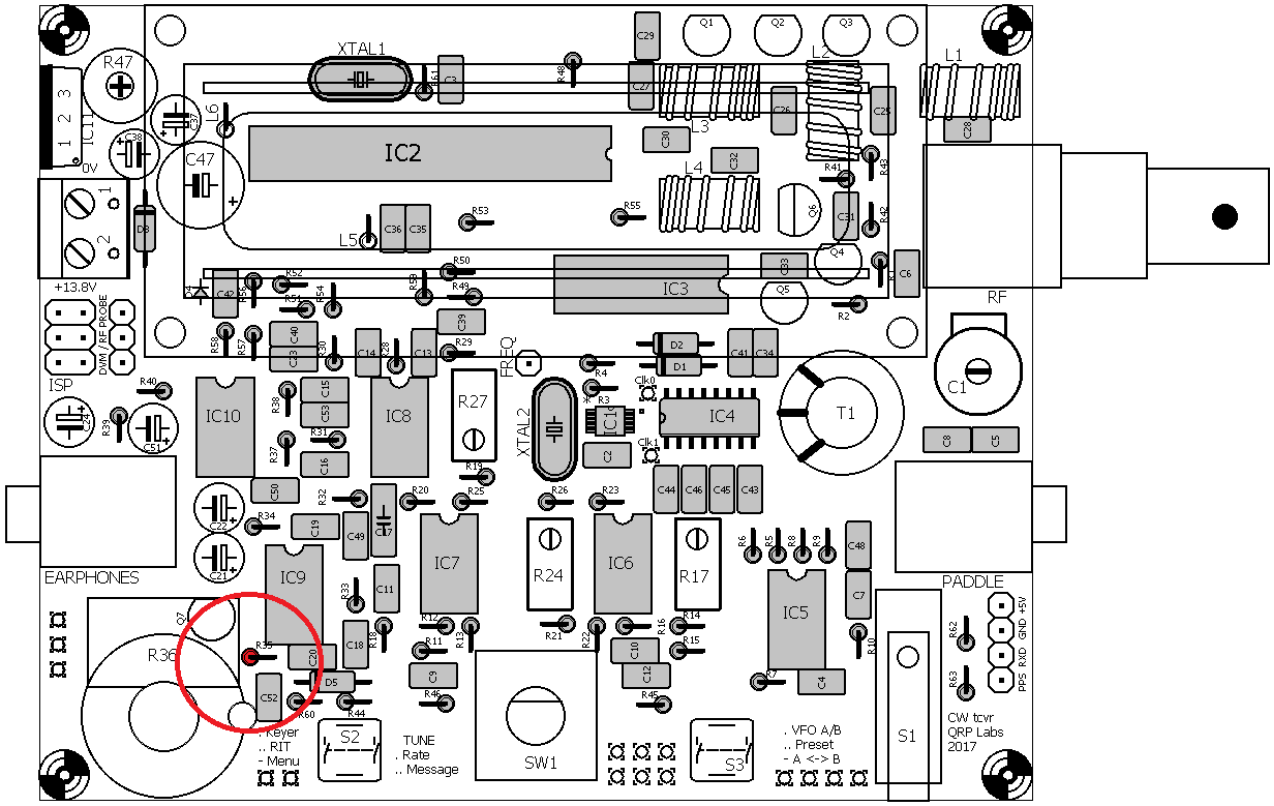
3.34 Install 7.5K resistor R21

This resistor has colour code purple-green-black-brown-brown.



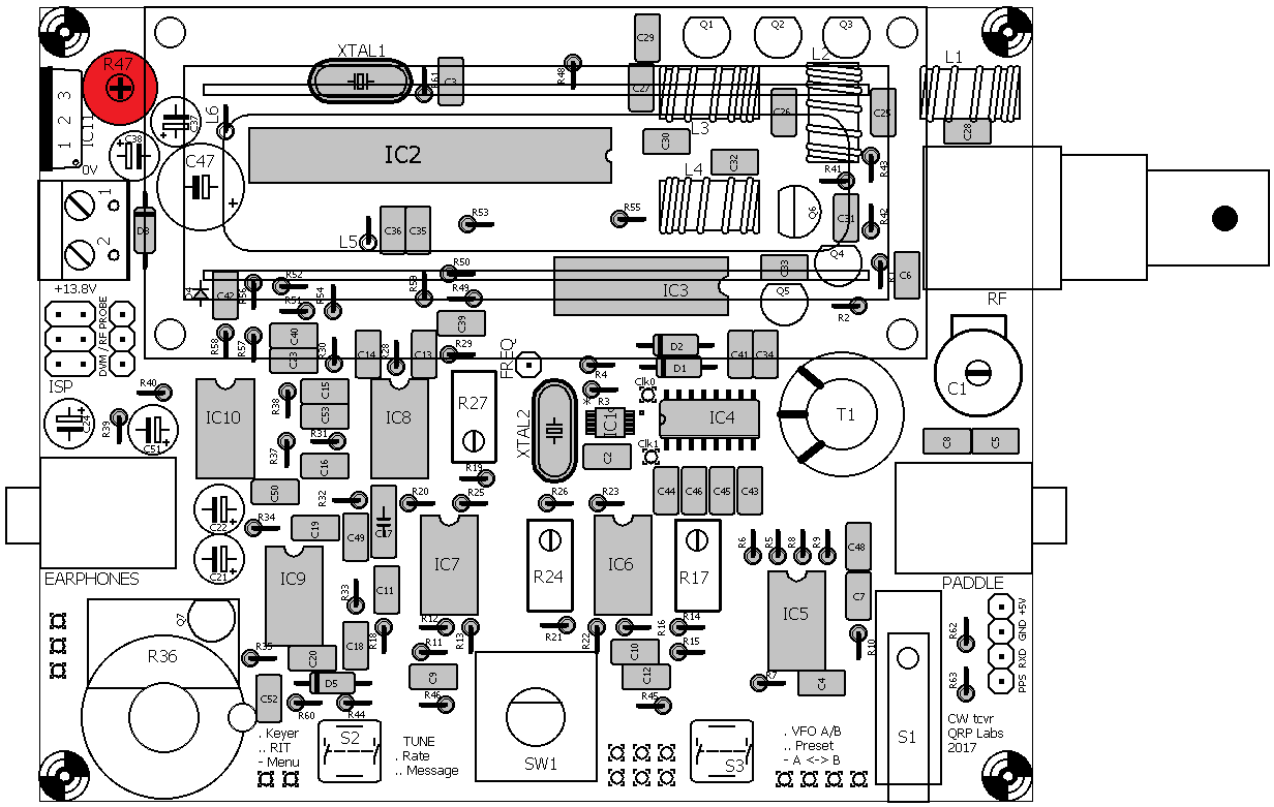
3.35 Install 750K resistor R35

This resistor has colour code purple-green-black-orange-brown.



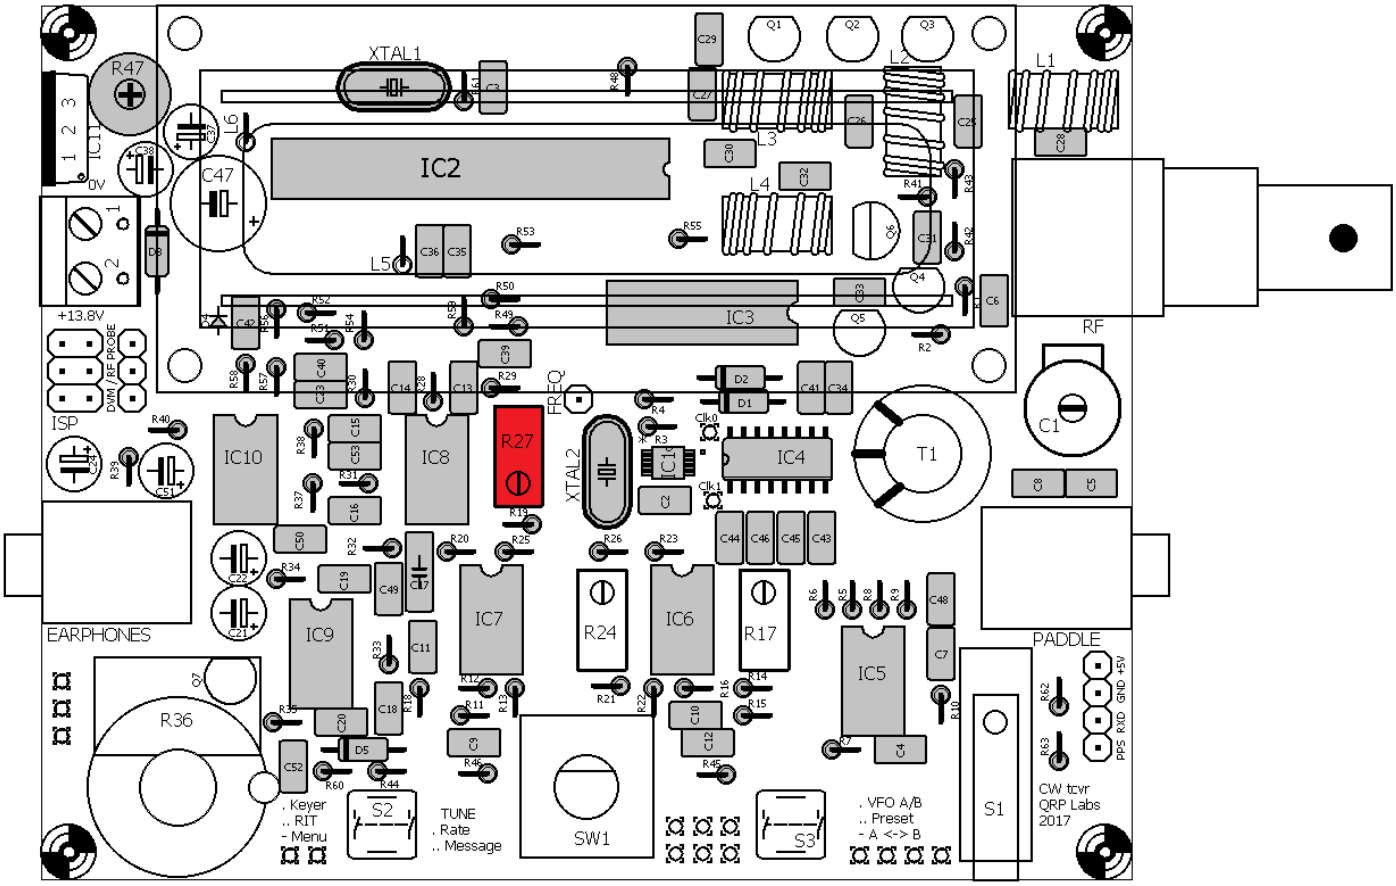
3.36 Install 100K trimmer potentiometer R47

This is the LCD contrast potentiometer. The label on R47 is “104”. Carefully apply firm pressure to install the component pins in the holes without bending them.



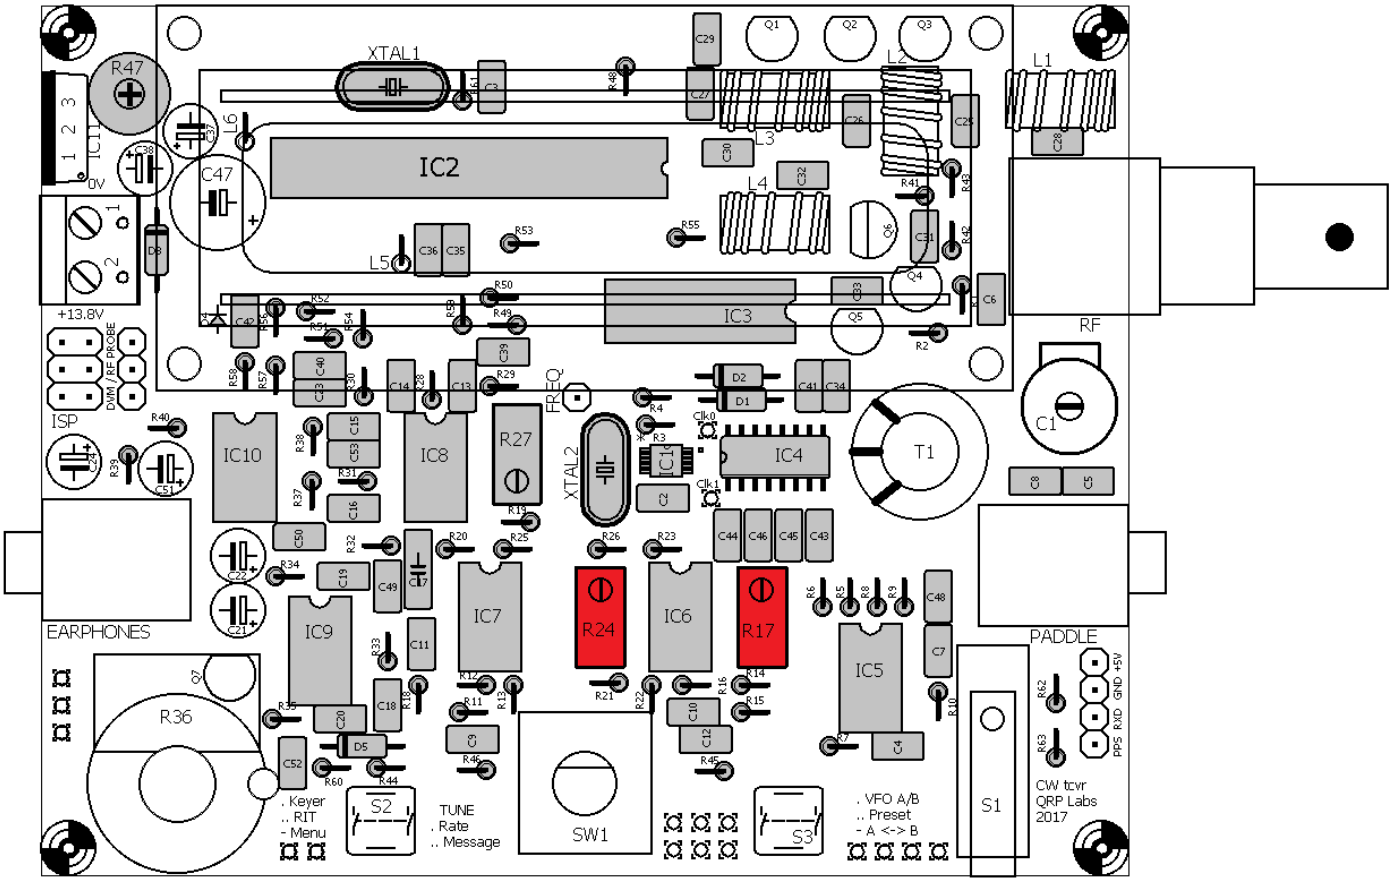
3.37 Install 500-ohm multi-turn trimmer potentiometer

This resistor is the small blue box component with label “501”. It is R27. Make sure that the orientation is correct. **The screw on the resistor must match the screw on the PCB silkscreen and layout diagram.**



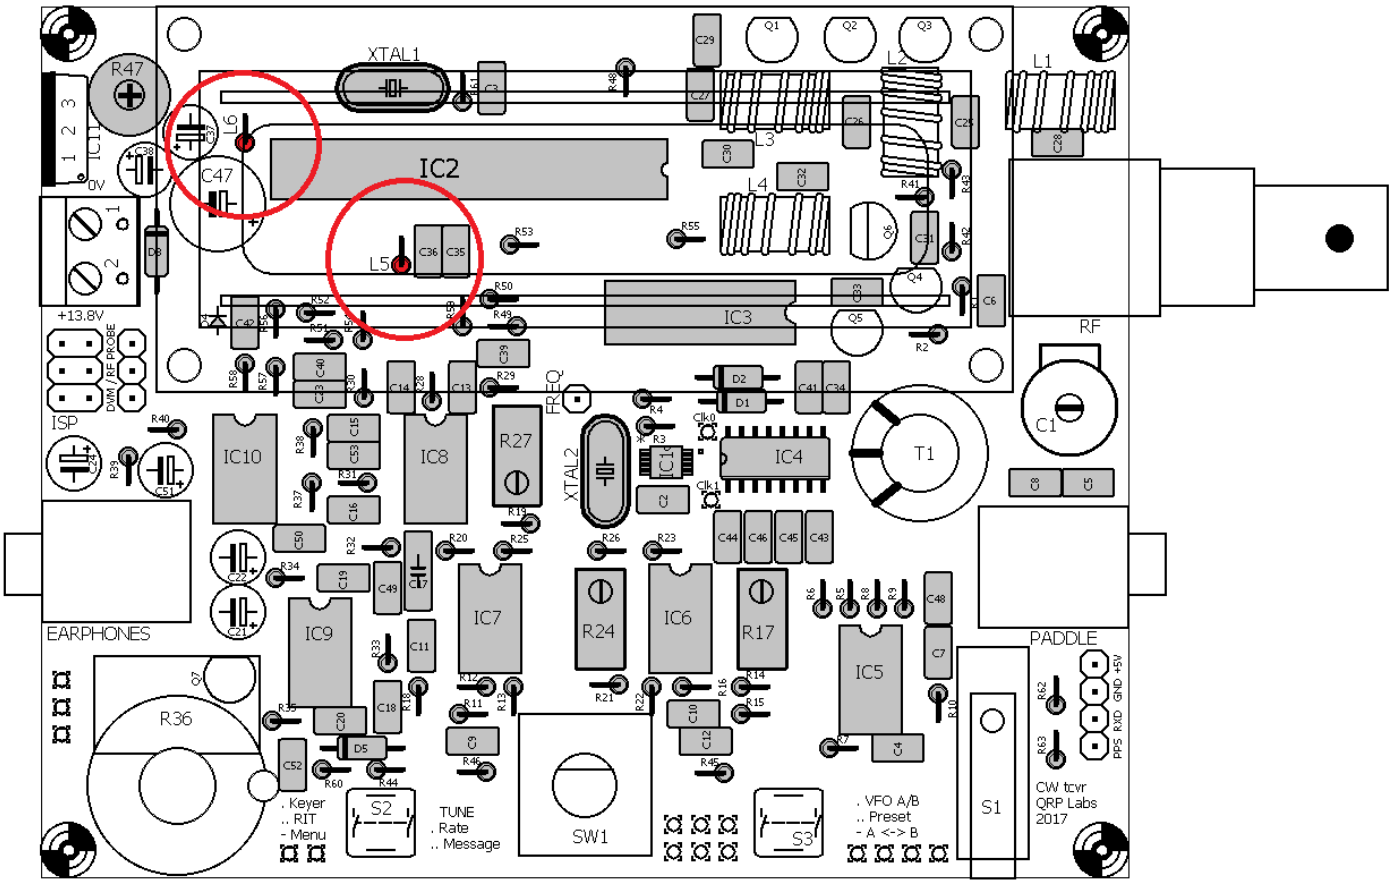
3.38 Install 50K multi-turn trimmer potentiometers

There are two 50K multi-turn trimmer potentiometers, R17 and R24. They are the small blue box components with label “’503”. Make sure that the orientations are correct. **The screws on the resistors must match the screws on the PCB silkscreen and layout diagram.**



3.39 Install two 100uH inductors

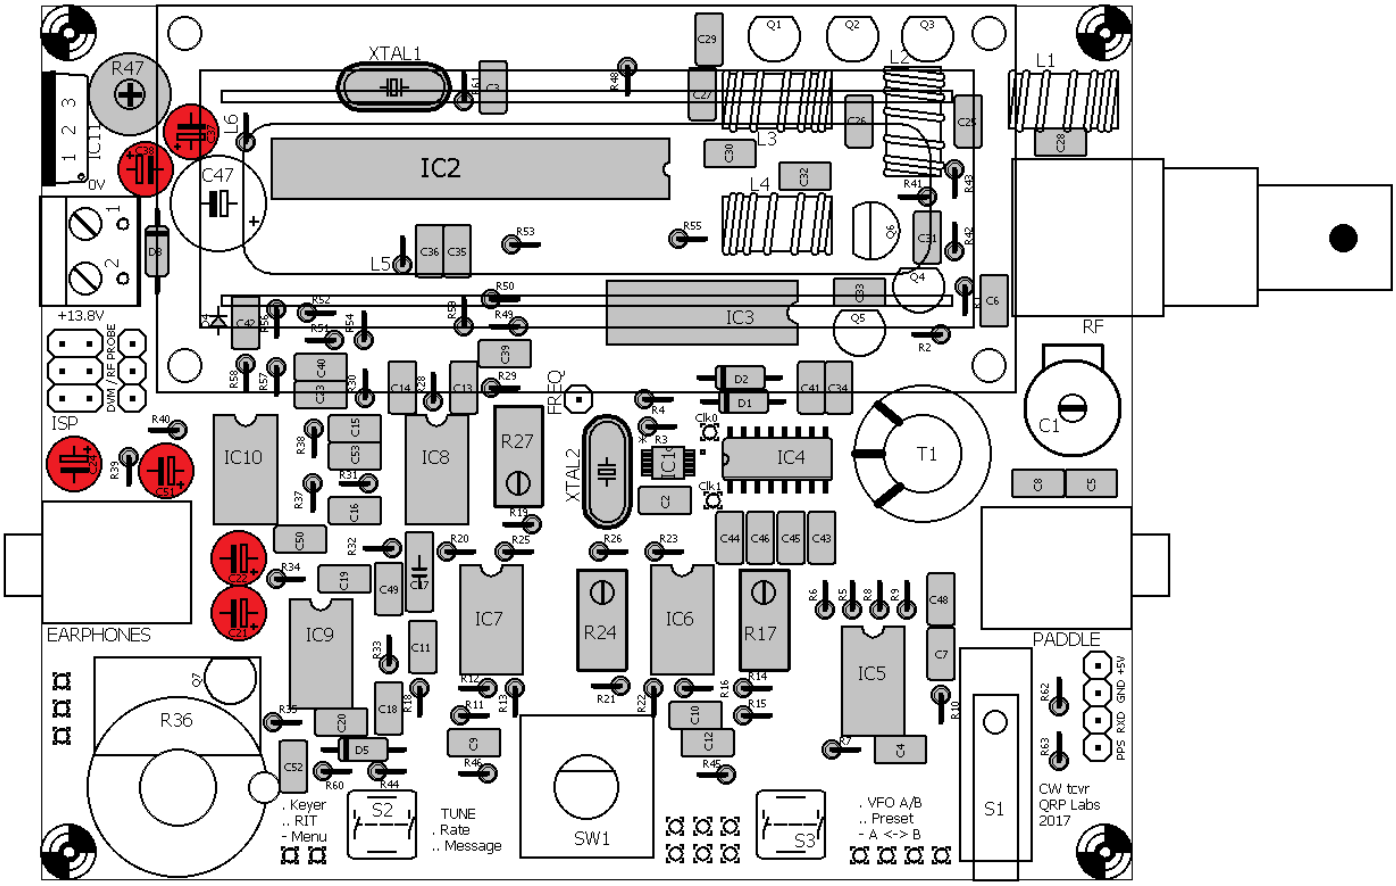
There are two 100uH inductors, L5 and L6. These look like short fat resistors. They are installed vertically on the PCB, in the same way as the resistors are installed.



3.40 Install 10uF capacitors

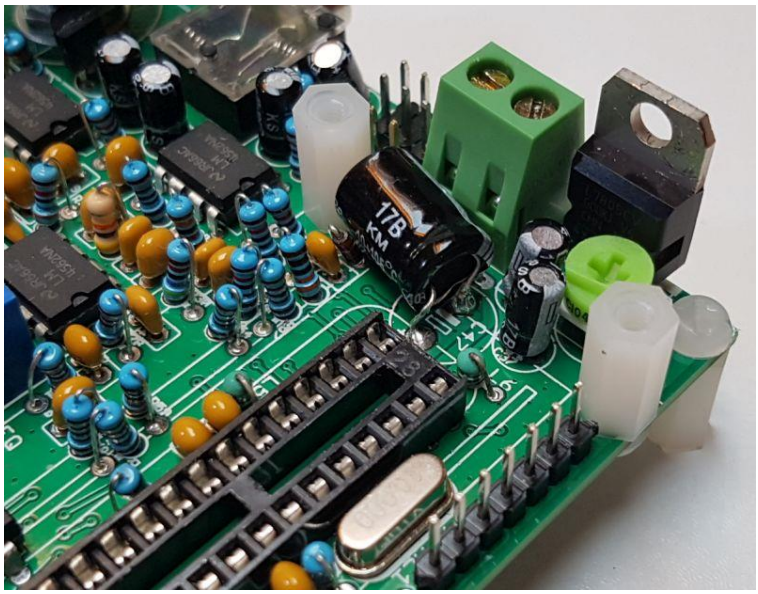
There are six 10uF capacitors in the kit: C21, C22, C24, C37, C38 and C51. These are polarised electrolytic capacitors and MUST be installed with the correct orientation! The capacitor NEGATIVE wire must be installed in the hole indicated on the PCB silkscreen and the layout diagram by the solid black bar; the POSITIVE wire must be installed in the hole indicated on the PCB silkscreen and the layout diagram by the hollow bar and the + symbol.

Electrolytic capacitors are also supplied with one wire longer than the other. The + wire is the longer wire, the – wire is the shorter one (see photo, right).



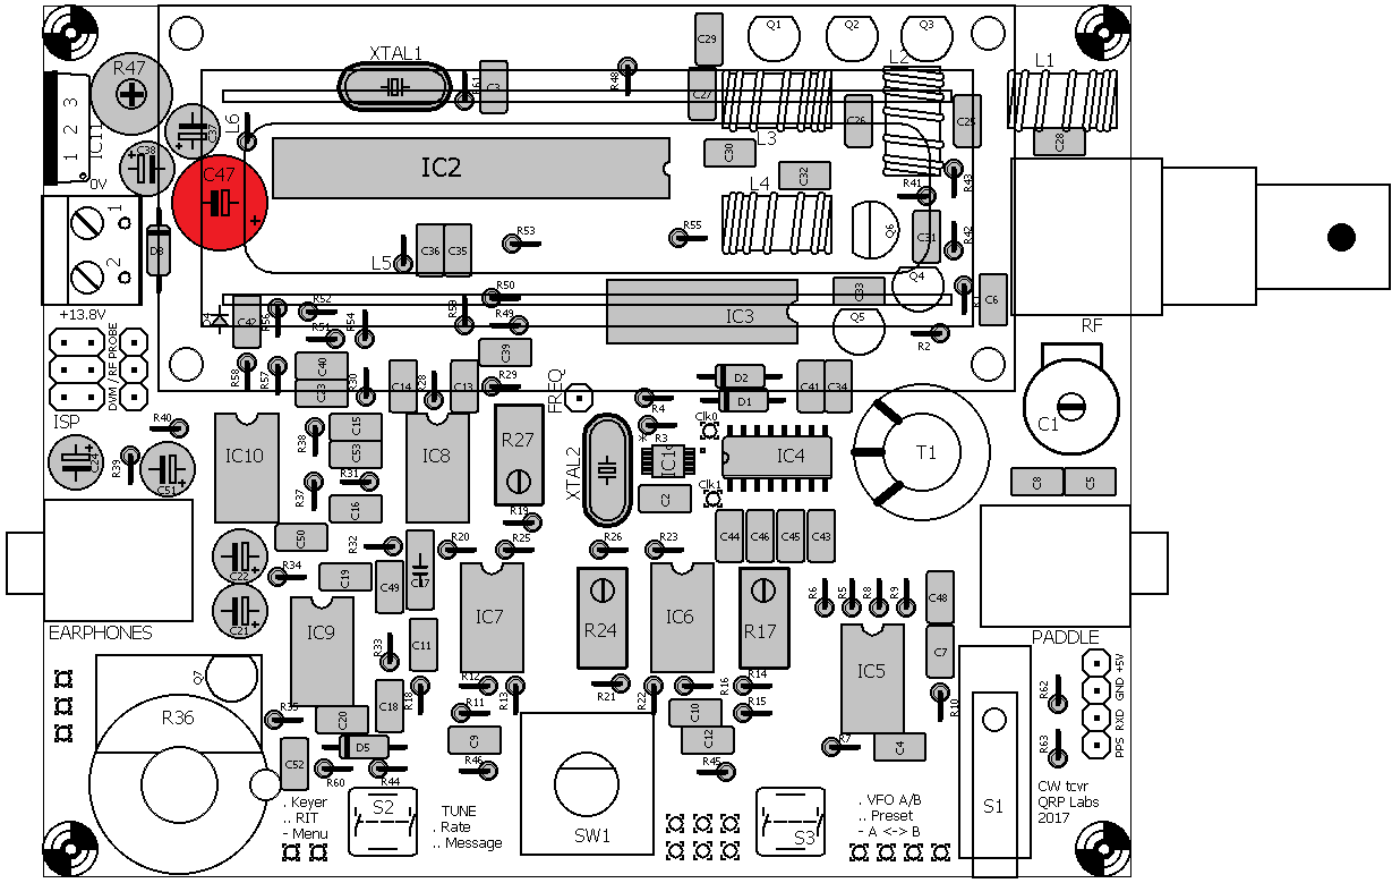
3.41 Install 220uF capacitor C47 (may be supplied as 470uF)

This capacitor is also a polarised electrolytic and must be orientated correctly (see former section).



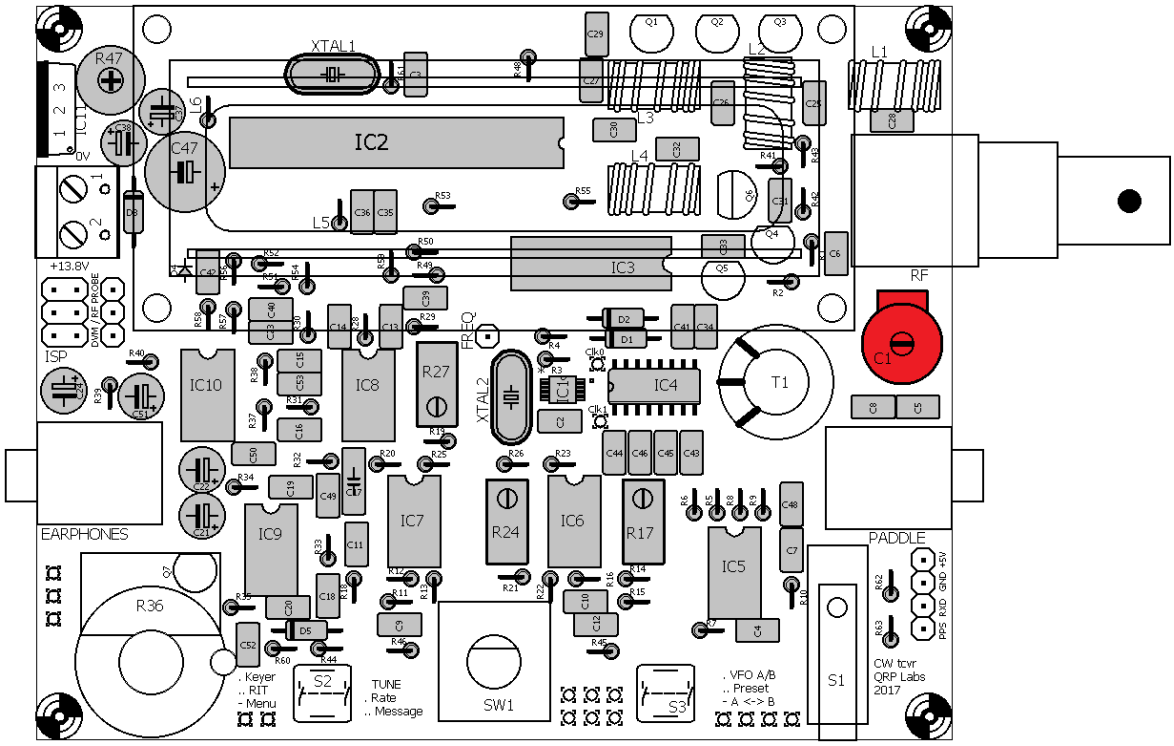
The height dimension of the supplied capacitor in the first batch (up to serial number 500) is enough that in some cases, if installed vertically on the PCB, it may touch some components on the bottom of the LCD module, once the LCD module is installed. Therefore, the recommended way to install this capacitor is orientated horizontally. Insert the wires into the holes (carefully putting the correctly polarised wires in the right holes) then bend the wires so that the capacitor lays horizontally over diode D3 (1N5819). Refer to the photograph (right). When the capacitor is in a suitable position, solder the wires as usual.

Kits from subsequent batches (approximately serial number 500 and above) do not need to mount the capacitor horizontally, because the supplied capacitor is small enough to fit under the LCD.



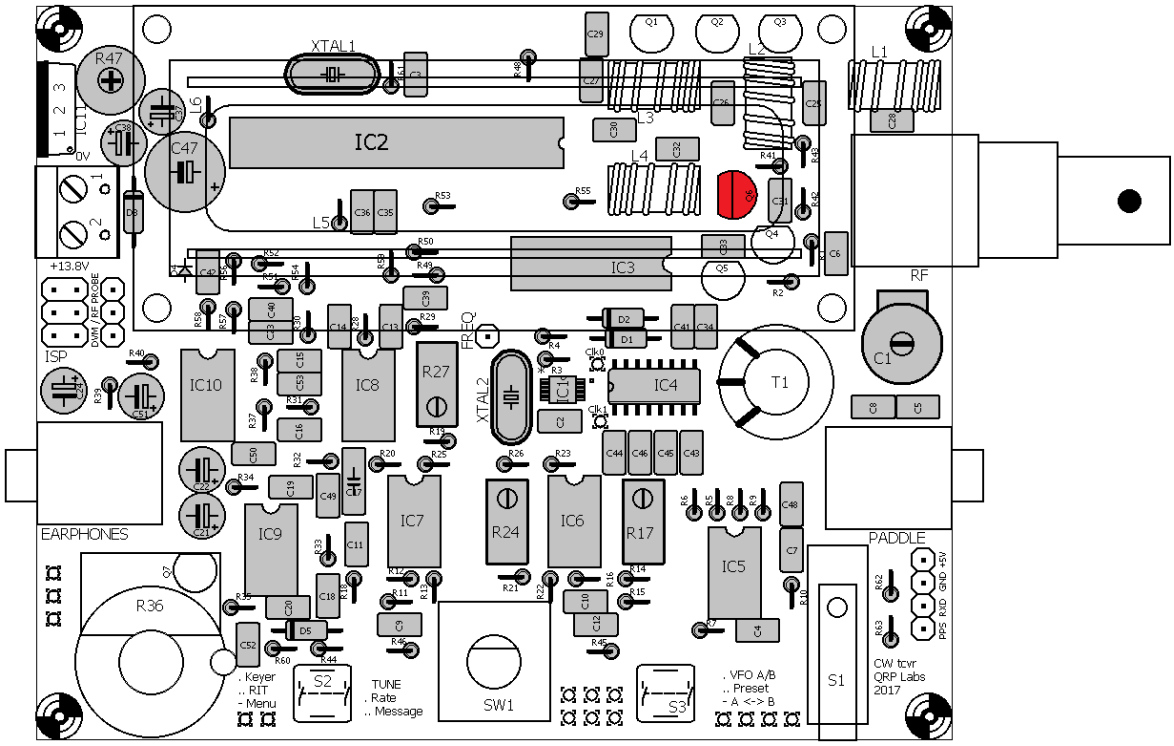
3.42 Install 30pF trimmer capacitor C1

Insert the component pins carefully and solder them QUICKLY to avoid overheating the capacitor which could melt the plastic insulating spacers.



3.43 Install MPS751 transistor Q6 (MPS2907 in first kit batch)

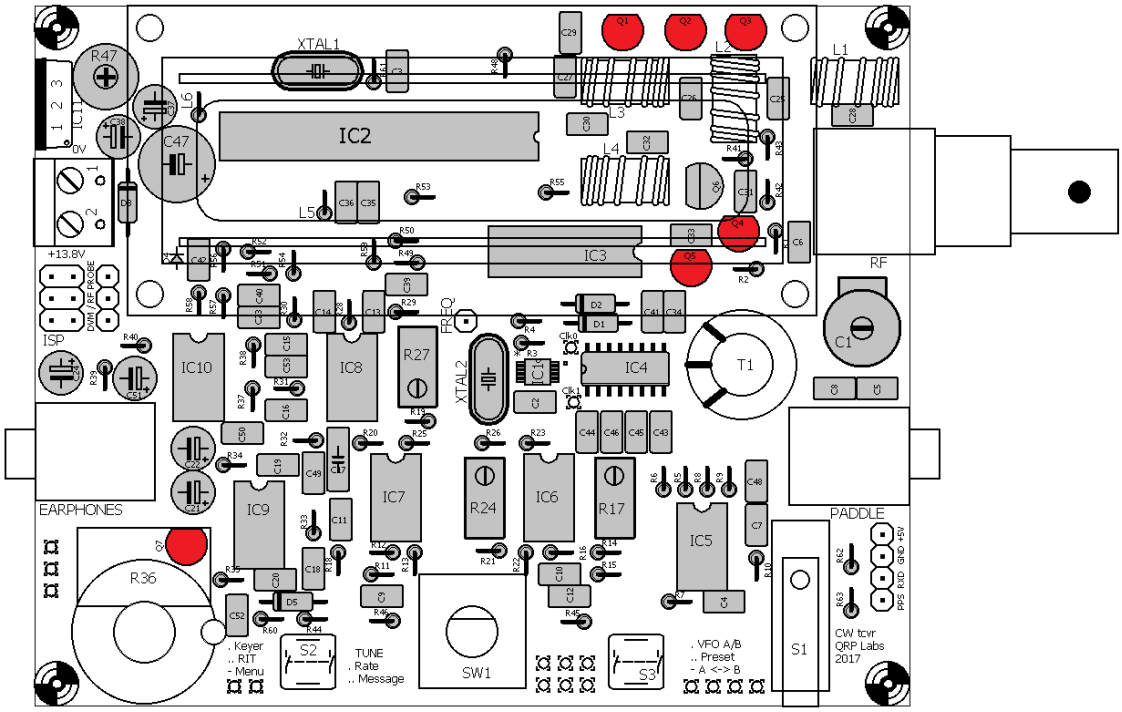
Be careful to correctly identify this transistor by its markings, as the package style is similar to the other transistors. Carefully bend and insert the wires so that the transistor orientation matches the PCB silkscreen and the layout diagram. Carefully push the transistor down towards the PCB until the wires between the PCB and the transistor body are about 5mm long, then solder.



3.44 Install all BS170 transistors

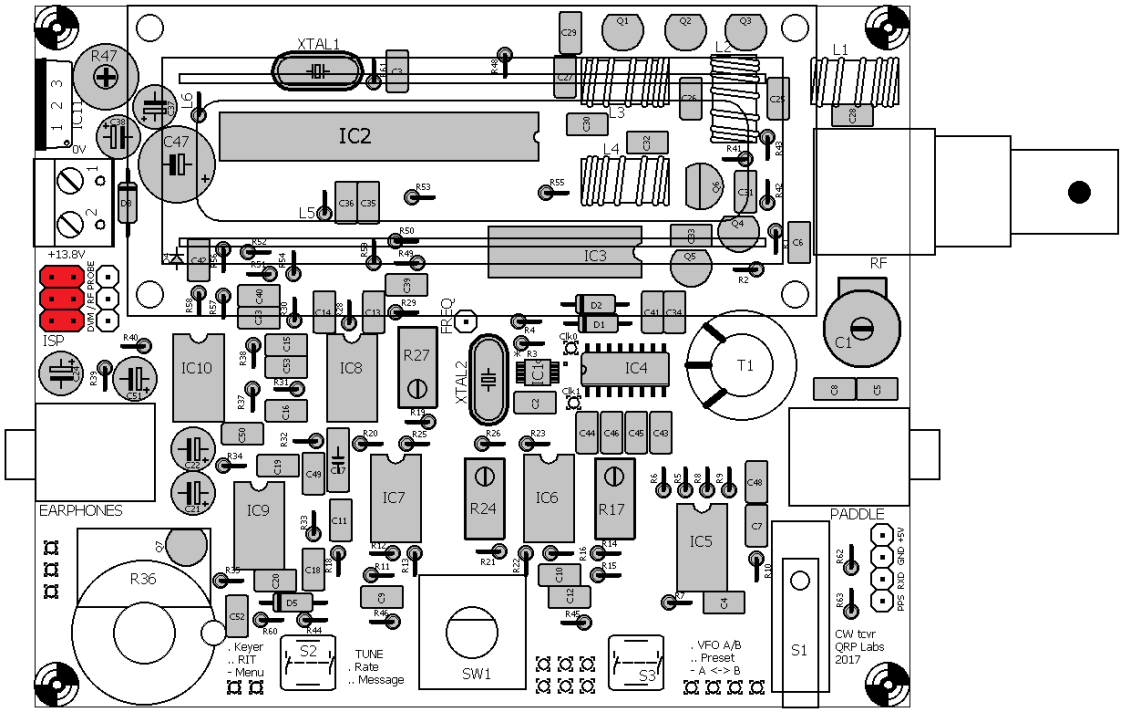
The remaining transistors in the kit are BS170 MOSFETs and there are six of them: Q1, Q2, Q3, Q4, Q5 and Q7. Follow the same installation procedure as the previous section.

Note that Q7 sits under the volume (gain) knob. It is important to ensure that Q7 is pushed down as far as possible towards the board, so that the transistor lead length is only ~4mm, to avoid the top of the transistor blocking the knob.



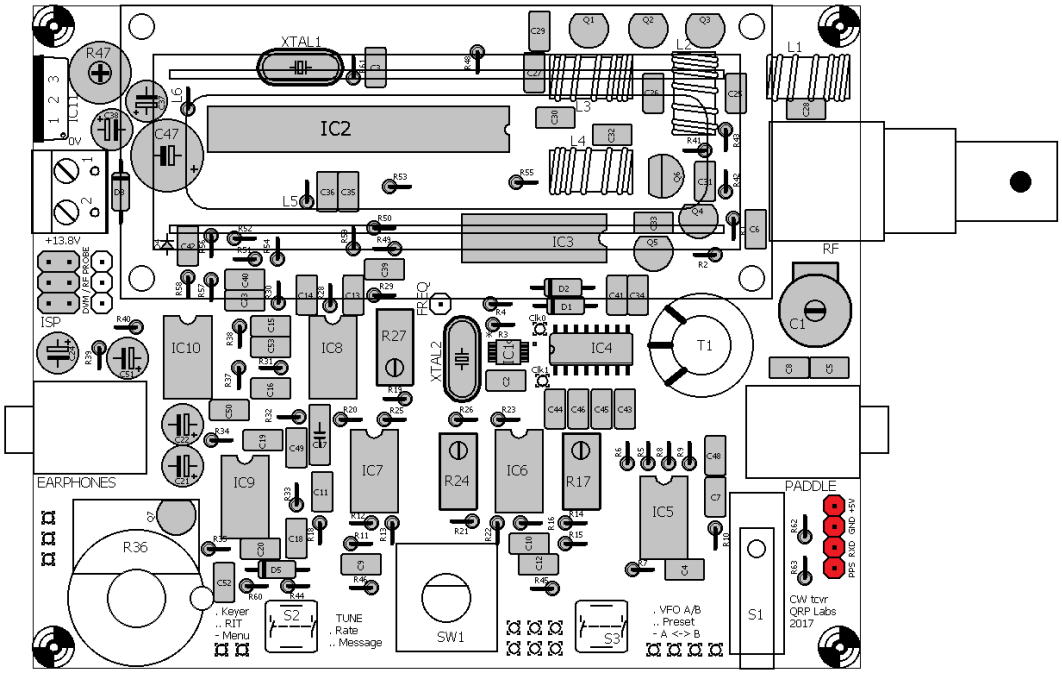
3.45 Install 2x3-pin in-circuit programming header

This pin header can be used to connect an AVR Programmer to apply firmware updates if desired. Insert the SHORT end of the pins into the PCB. Solder one pin in place first and check that the header is nicely seated on the PCB before soldering the other 5.



3.46 Install 4-pin GPS header

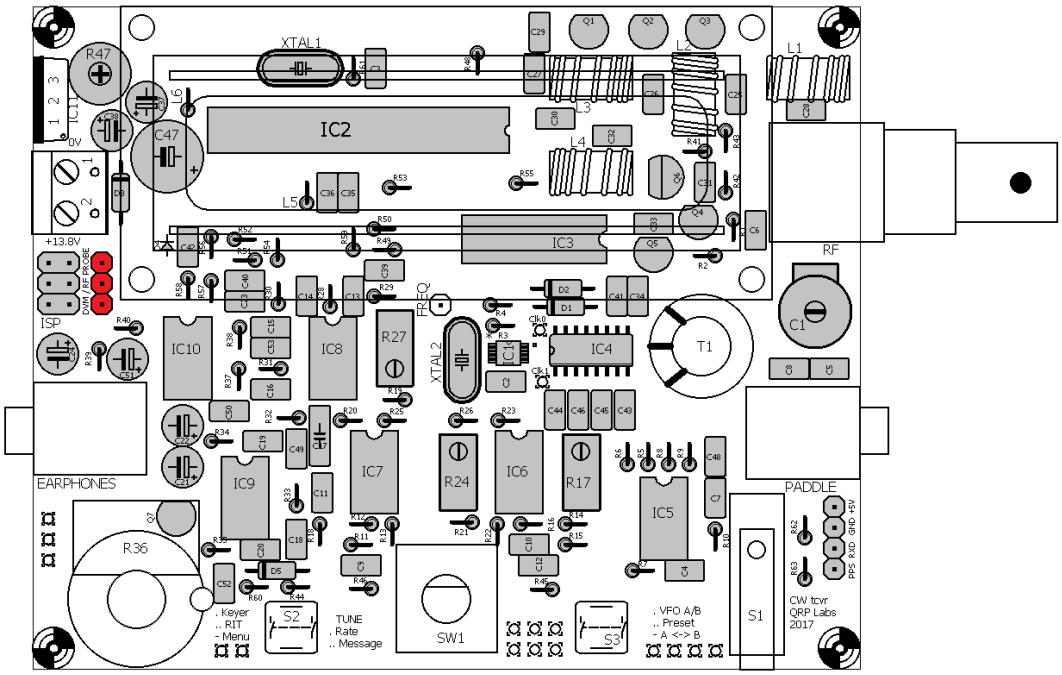
Install a 4-pin header from the Low Pass Filter kit bag, in the position shown. This is used to connect a GPS module if required. Insert the SHORT end of the pins into the PCB.



3.47 Install 3-pin DVM/RF detector header

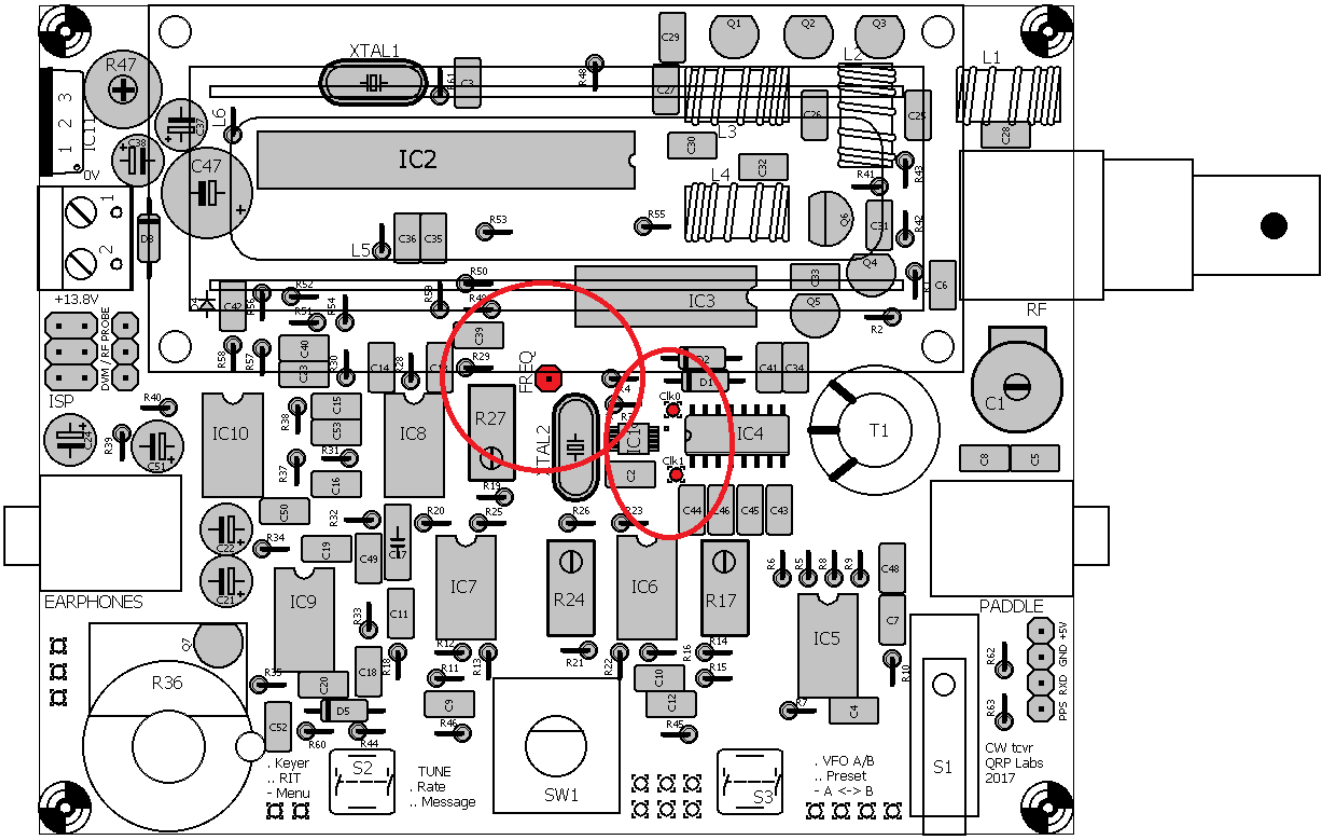
Take the other 4-pin header from the Low Pass Filter kit and carefully cut off 1 pin with a wire-cutter, without damaging its plastic base. The headers are designed to break apart easily like this. Keep the 1-pin section safely.

Install the 3-pin header section as shown. Insert the SHORT end of the pins into the PCB. This is used as the input to the DVM (voltmeter) and RF power meter functions of the kit. You can later jumper pins 1 to 3 to measure the supply voltage with an icon on the LCD during operation.



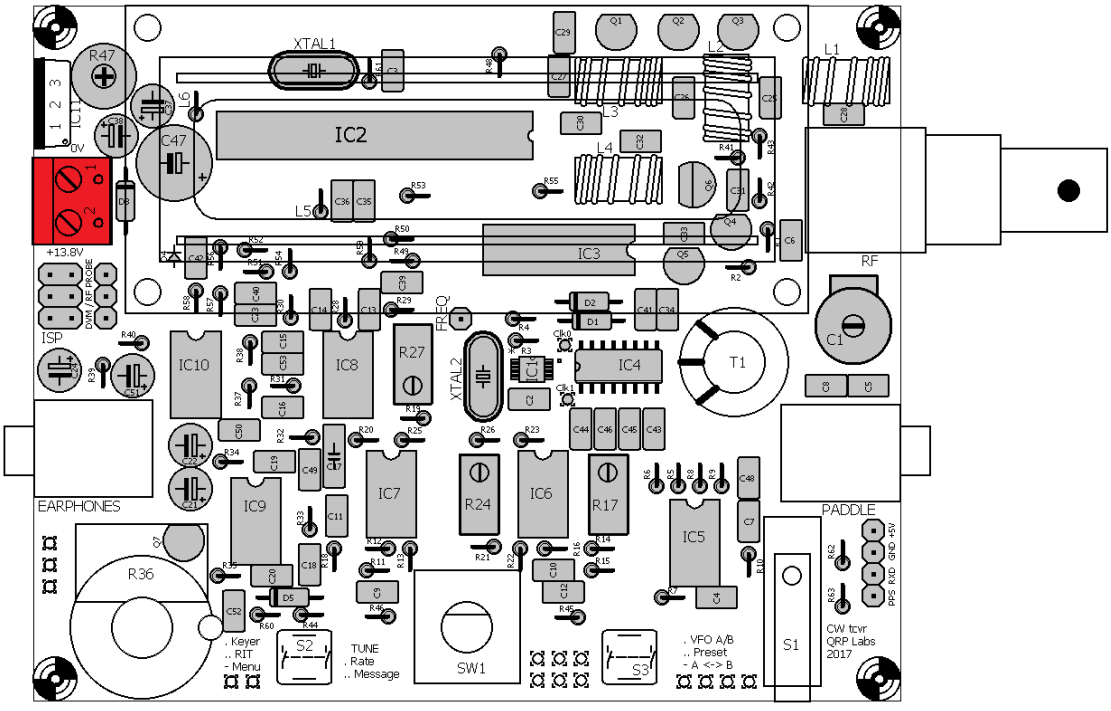
3.48 Install 1-pin test points

Install 1-pin headers as test points, as shown. One of these is taken from the 4-pin header from the Low Pass Filter kit (see previous section); the other two are to be cut carefully from the 16-pin header supplied, leaving the 14-pin section intact.



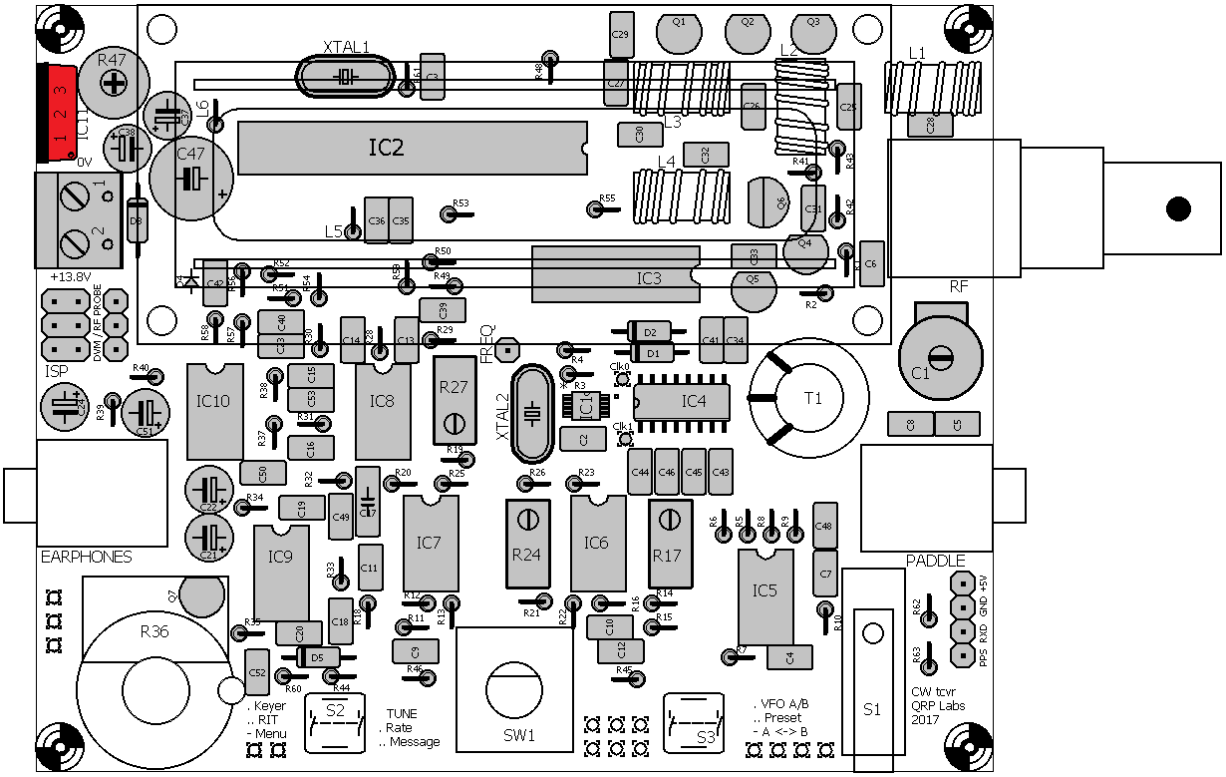
3.49 Install power connector

Install the 2-way power connector as shown, orientated to match the PCB silkscreen and have the terminal openings facing outwards from the PCB to facilitate installing power wires later.



3.50 Install 7805 voltage regulator IC11

Install the 7805 voltage regulator, orientating it so that the metal tab is facing outwards from the PCB. Push the wires all the way down into the holes until the body of the regulator is about 5mm off the PCB surface. Solder and trim the excess wires under the board.

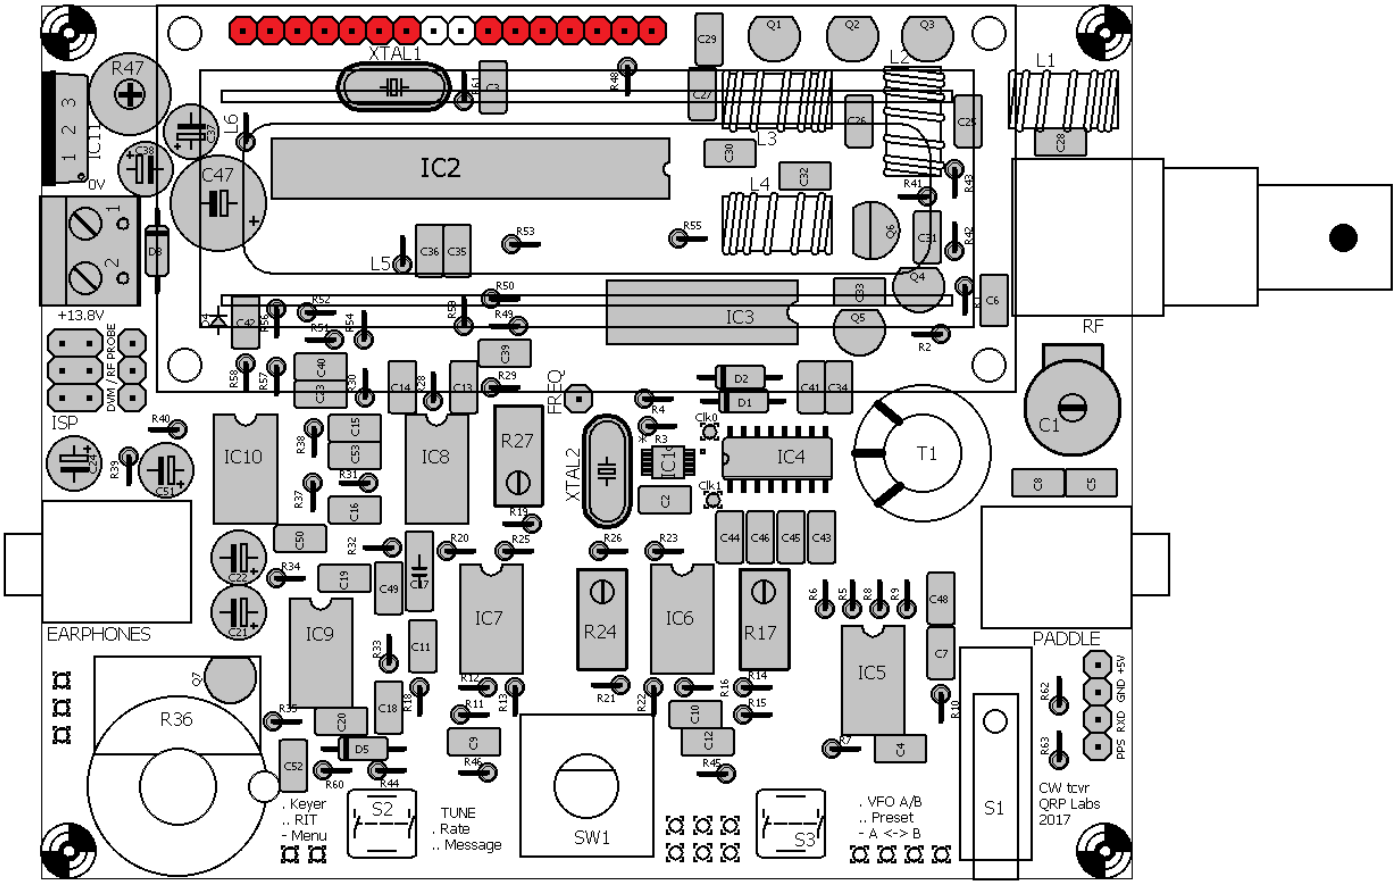


3.51 Install pin headers for the LCD module

The LCD has a 16-way connector. If you have been following me so far, you have already carefully cut off two of the pins, to use in the Clk0 and Clk1 test points. Therefore, you only have a 14-pin header remaining. This is fine, since not all of the pins of the LCD module are used! The LCD module has an 8-bit data bus, but can also be operated in 4-bit data mode, which is what is done in this kit. The 4-bit mode has the advantage that less pins of the microcontroller are used! This is very important in this design, because we require so many control pins from the microcontroller for the various functions of the radio. So, the LCD has 16 pins but the central 4 pins are not used.

Now break the 14-pin header carefully in half so that you have two 7-pin sections. (If you make a mistake and you have one 8-pin section and one 6-pin section, that is still Ok).

Install the two sections into the 16-pin holes on the PCB leaving an empty gap of two pins in the middle. Insert the SHORT end of the pins into the PCB. **Be very careful to ensure that the pin headers are accurately aligned to the PCB, so that later when we install the LCD module everything fits accurately.**



3.52 Wind and install toroid L4

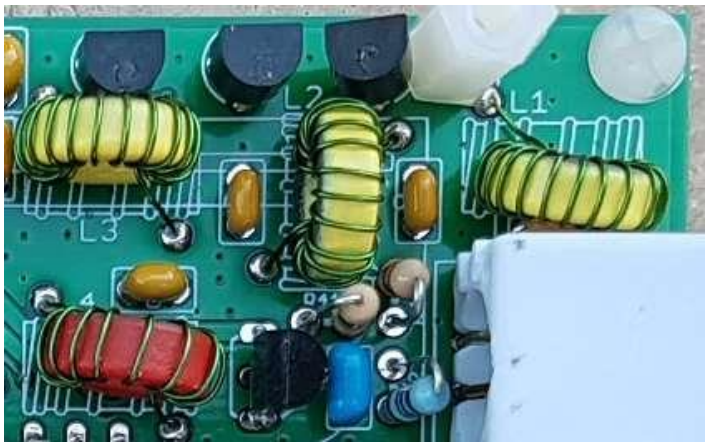
L4 is type T37-2. It is a small ring with red paint on one side. Each time the wire passes through the hole in the middle of the toroid, this counts as one turn. The number of turns depends on the band of your kit, refer to the following table. Inductance values are approximate and will depend on variations in the core, and how tightly you wind the turns. Do not worry about these variations which are not critical in this case.

Band	Value	Turns
80m	2.3uH	24
60m	2.3uH	24
40m	1.0uH	16
30m	0.78uH	14
20m	0.40uH	10
17m	0.32uH	9

Try to keep the wire quite tight (but not so tight that you break the wire). Try to spread the turns evenly around the toroid. Leave about 2cm or 3cm of wire at the ends.

The wire is coated with an enamel insulating paint and it is **CRITICAL to remove this enamel at the soldered joints otherwise there will be no electrical connection through the toroid! This is the number 1 cause of problems with QRP Labs kit construction: failure to remove the wire enamel.**

One method of removing the wire enamel is to scrape it off at the ends, either with sandpaper, or carefully scratching with a knife or wire cutters. However, my favourite method is just to burn off the enamel. For quite a number of years, the type of enamel used on copper wire can be burnt off using the temperature available from an ordinary soldering iron, immersing the wire in a blob of solder. (This was not the case, with much older wire found in vintage valve/tube equipment). You could also use a cigarette lighter to burn off the enamel.

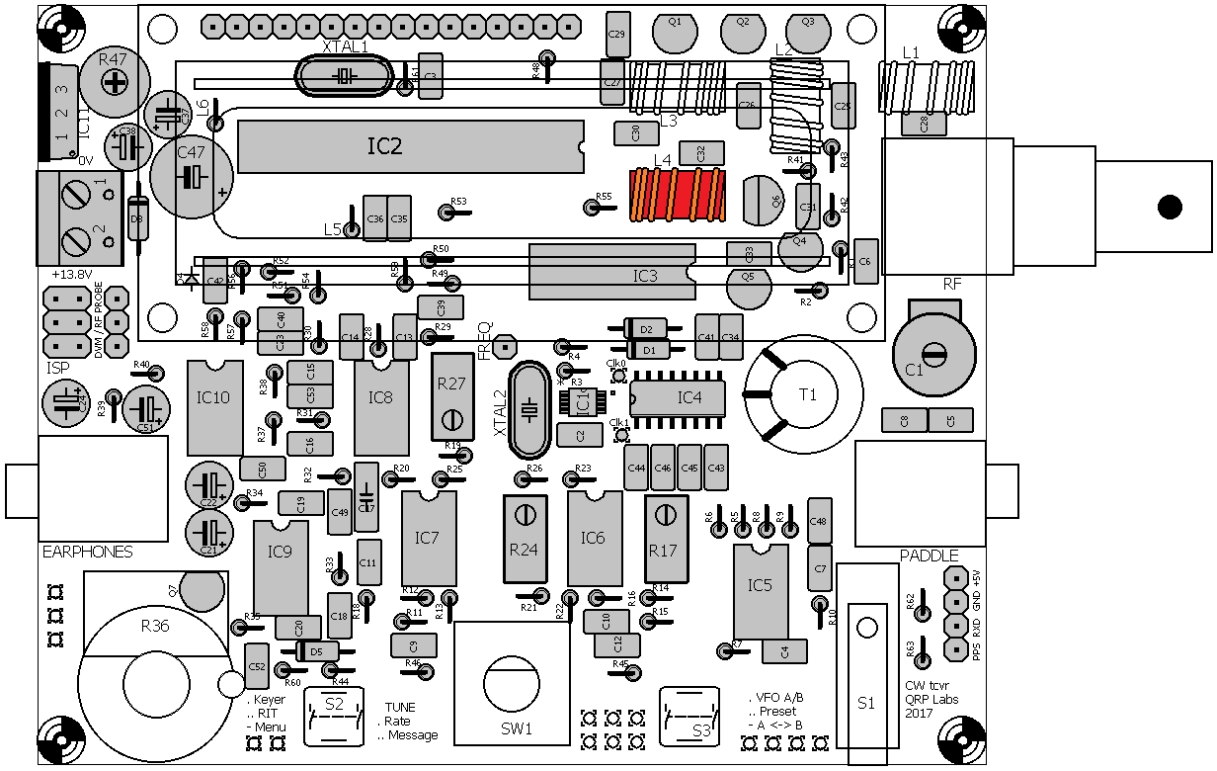


Insert the ends of the wires into the correct holes of the PCB and pull it through tight, so that the toroid sits up vertically on the PCB. See photo, right.

Bend the wires over so that the toroid does not fall out while you are trying to solder the wires. Cut off the excess wire using wirecutters, leaving only about 2mm protruding through the PCB on the lower side. Now apply solder quite generously from the soldering iron. Hold the soldering iron to the joint for a few seconds – I usually count to 10 slowly – and the solder will surround the wire, which will become hot enough to burn off the enamel. You can sometimes see a small puff of smoke when the enamel burns off.

Carefully inspect the soldered joints with a magnifying glass to make sure that the wire is correctly soldered. If it looks like the solder hasn't flowed nicely and adhered to the wire, then this is usually a sign that the enamel probably hasn't been burnt off.

If you have a DVM it is a good idea to check for DC electrical continuity (zero ohms resistance) between the two ends of the wire. If you do NOT have a DVM and if the radio doesn't work, then we can use the built-in test equipment later, to trace the fault.

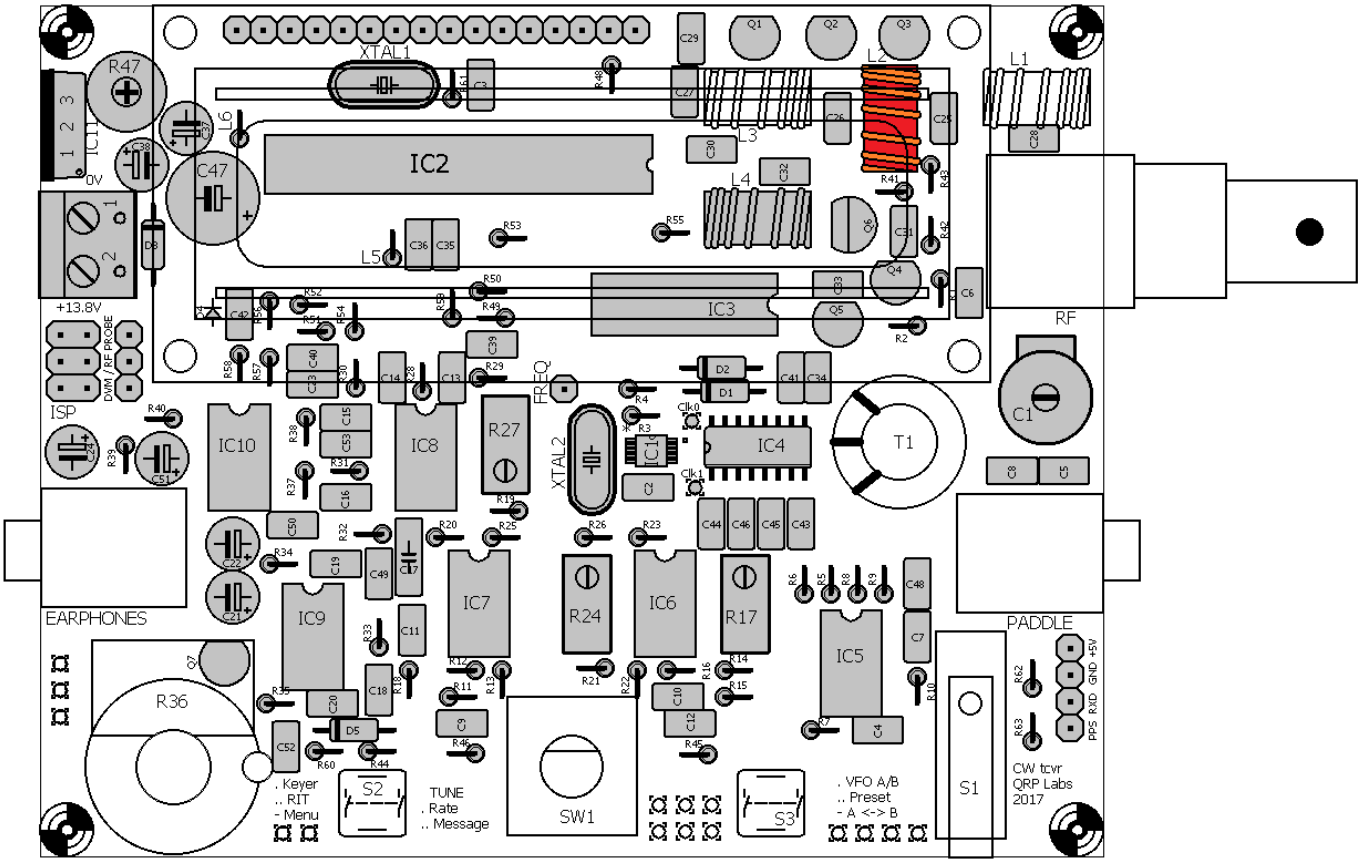


3.53 Wind and install toroid L2

L2 is a small toroid ring painted yellow or red on one side. It is part of the supplied Low Pass Filter kit bag. Again, keep the wire tight and evenly spaced around the toroid. Installation of the inductor is similar to the previous section. **Remember to remove the wire enamel and check!**

The number of turns is band-dependent, refer to the following table. Inductance values are approximate and will depend on variations in the core, and how tightly you wind the turns. Do not worry about these variations which are not critical in this case.

Band	Toroid	Colour	Value	Turns
80m	T37-2	Red	3.0uH	27
60m	T37-2	Red	2.3uH	24
40m	T37-6	Yellow	1.7uH	24
30m	T37-6	Yellow	1.3uH	20
20m	T37-6	Yellow	0.90uH	17
17m	T37-6	Yellow	0.67uH	15

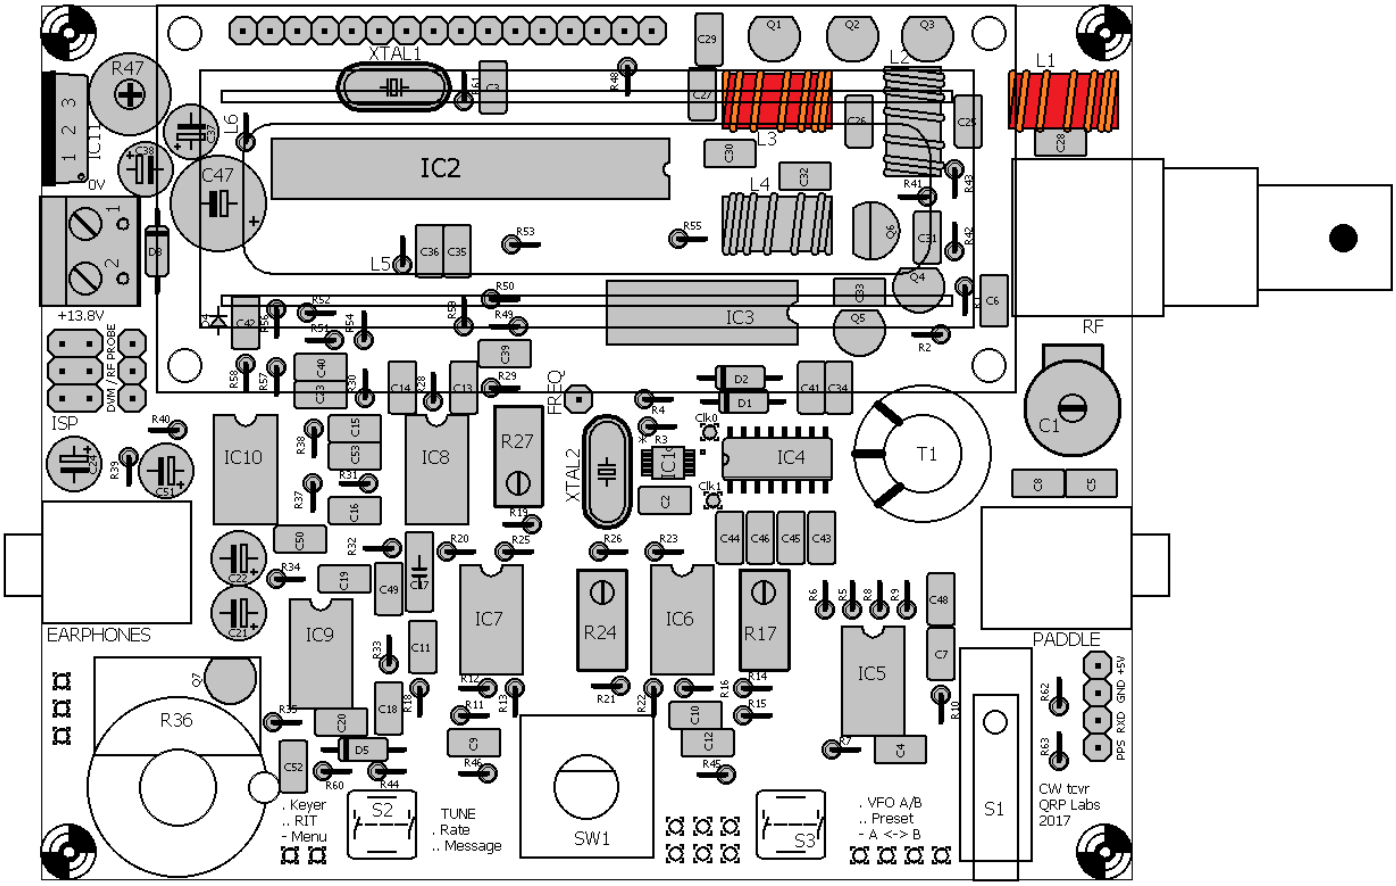


3.54 Wind and install toroids L1 and L3

L1 and L3 are small toroid rings painted yellow or red on one side. They are part of the supplied Low Pass Filter kit bag. Again, keep the wire tight and evenly spaced around the toroid. Installation of the inductor is similar to the previous section. **Remember to remove the wire enamel and check!**

The number of turns is band-dependent, refer to the following table. Inductance values are approximate and will depend on variations in the core, and how tightly you wind the turns. Do not worry about these variations which are not critical in this case.

Band	Toroid	Colour	Value	Turns
80m	T37-2	Red	2.4uH	25
60m	T37-2	Red	2.1uH	23
40m	T37-6	Yellow	1.4uH	21
30m	T37-6	Yellow	1.1uH	19
20m	T37-6	Yellow	0.77uH	16
17m	T37-6	Yellow	0.55uH	13



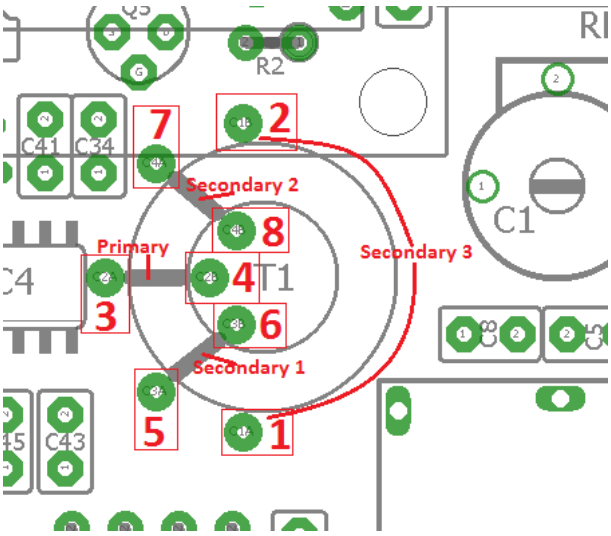
3.55 Wind and install transformer T1

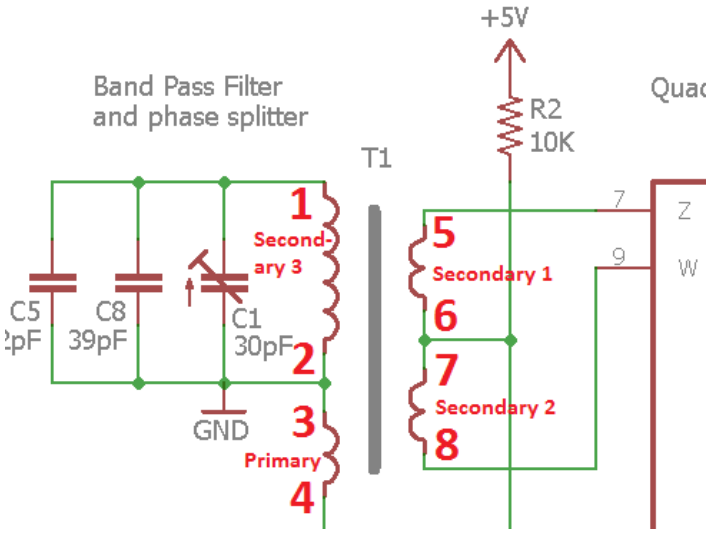
Now we come to the only really tricky piece of the assembly, which is the receiver input transformer T1. Follow these instructions carefully, it is tricky but quite feasible if you go step by step.

In the end, you are going to end up with an installed transformer which hopefully looks something like the photo (right, shows 20m version).

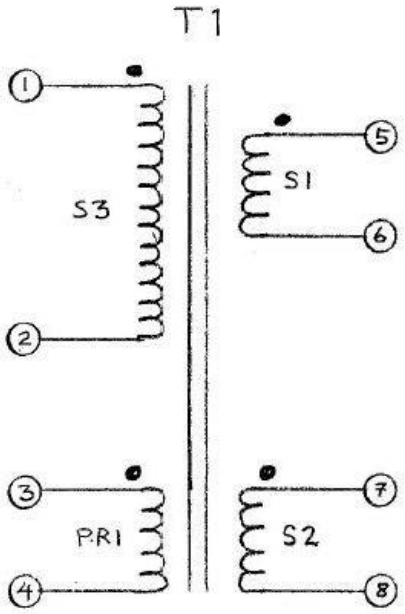
This transformer has FOUR windings. Three identical short windings, and one long winding. There are therefore eight wire ends, which must all be soldered into the correct holes on the PCB, and with the enamel properly removed.

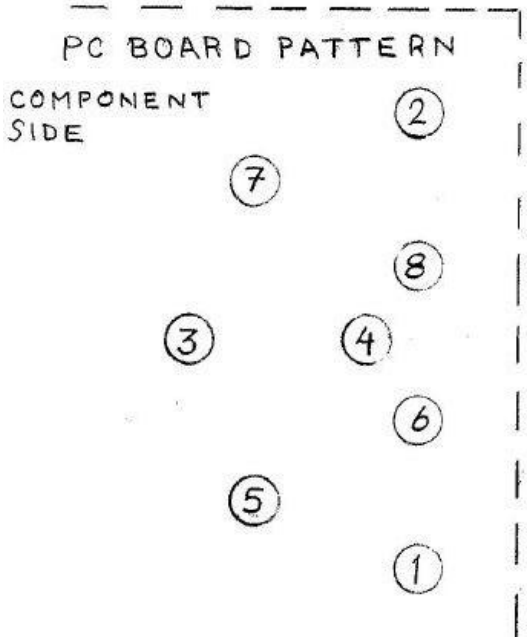
Here are two diagrams which enumerate each of the windings, wire endings and holes on the PCB, on both the layout diagram and on the circuit (schematic) diagram. It should help to explain diagrammatically which wires must go where.

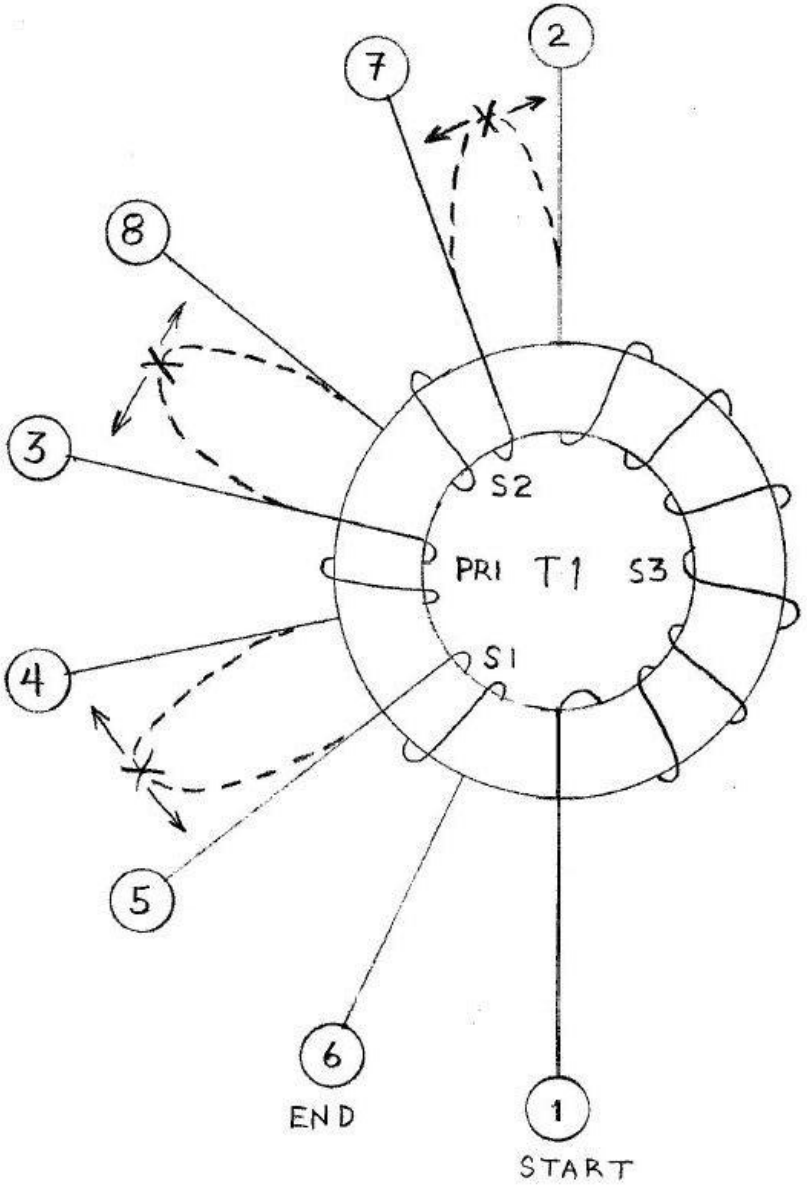




On the following page is a diagram hand-drawn by Ed WA4MZS (thanks Ed!) which may also clarify the construction and installation of T1.



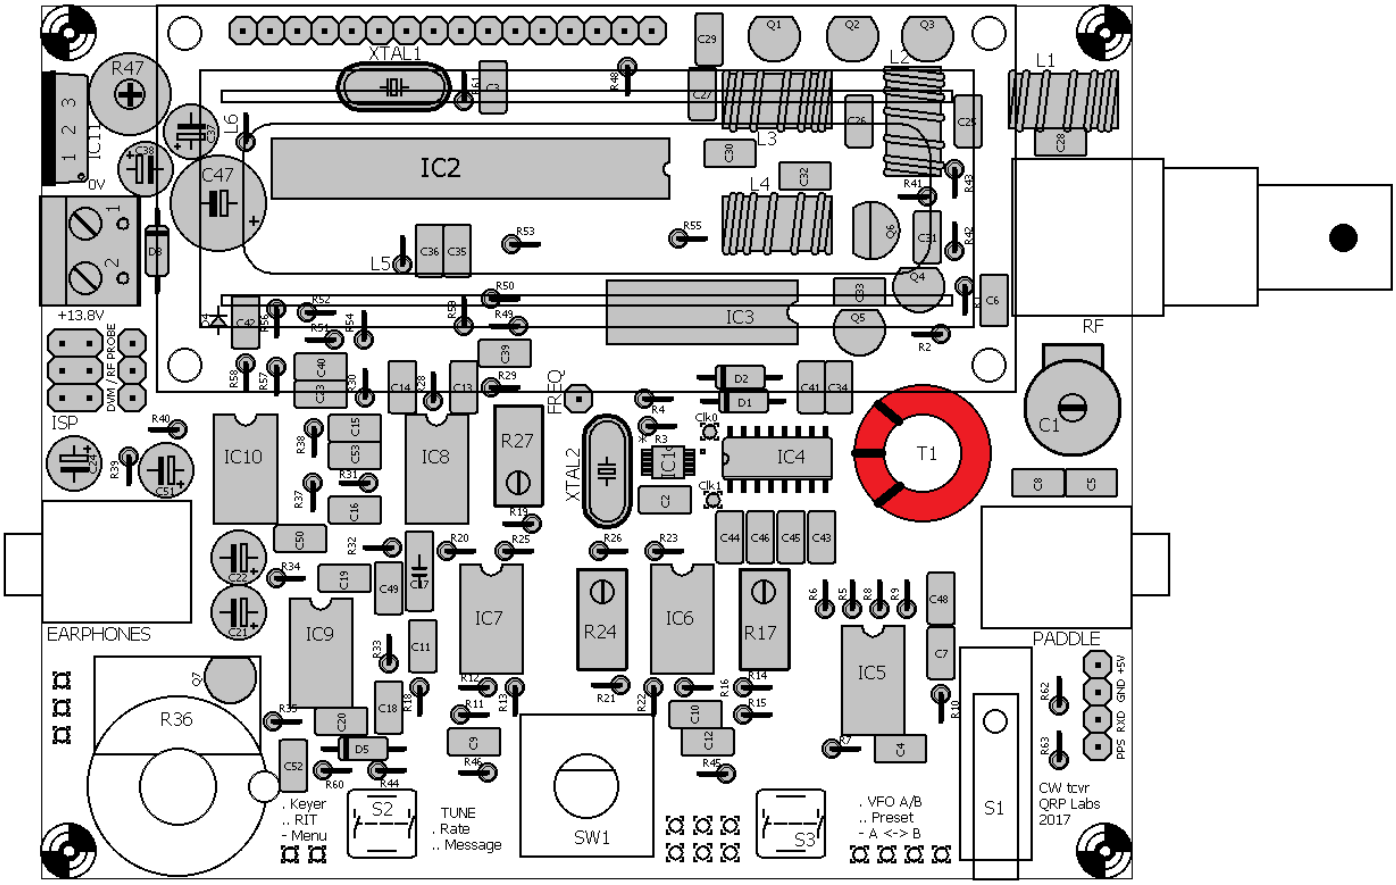




BAND	PRI	S1	S2	S3
80m	5T	5T	5T	68T
60m	5T	5T	5T	46T
40m	5T	5T	5T	38T
30m	4T	4T	4T	30T
20m	3T	3T	3T	30T
17m	3T	3T	3T	22T

CORE = T50-2

WIND W/ # 28 ENAM.
(0.33 mm)



The four windings on T1 must all be in the same “sense”. There are two ways to wind toroids. You might call them left-handed and right-handed; clockwise and counter-clockwise; whether the wire goes through the toroid from top to bottom, or from bottom to top. Whatever you call it, all the four windings have to be the same, to be sure to get the phasing to the quadrature sampling detector correct.

The number of turns in each winding depends on the band you are building the kit for. Refer to the following table. For convenience, the remainder of the instructions in this section refer to the 20m version (30 + 3 + 3 + 3 turns).

But MAKE SURE you wind the correct number of turns for your band!

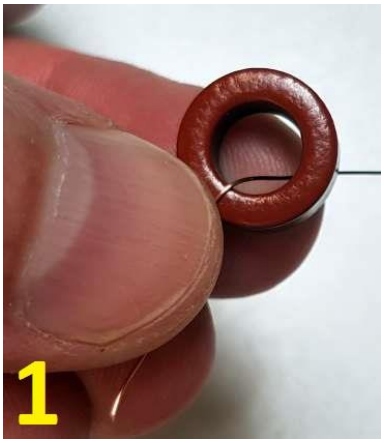
Band	Primary	Secondary 1	Secondary 2	Secondary 3
80m	5	5	5	68
60m	5	5	5	46
40m	5	5	5	38
30m	4	4	4	30
20m	3	3	3	30
17m	3	3	3	22

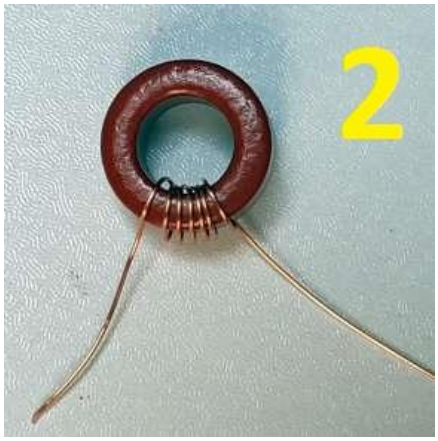
Note for 80m and 60m versions: the toroid ring is not large enough to neatly hold all of those turns in a single flat tidy winding. The large secondary winding WILL end up looking messy, with overlaps in some places. You should try to ensure any overlaps turns are evenly spaced throughout the winding! Do not try to wind one neat layer, then wind the remaining turns as an additional neat layer on top of that. Just go with the messy overlapping turns and don’t worry about it: everything will work fine, regardless.

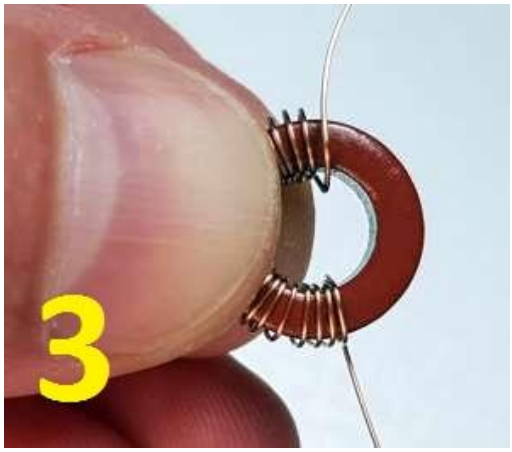
In all cases, there is one long secondary winding, and three other short identical windings. To make things easier, we will wind all windings together in one go, this will guarantee that the "sense" of each winding will be the same. At the intended breaks between the windings, we will leave large loops of wire, that we can later cut one by one to make sure the wires go in the correct holes.

There are a lot of steps listed below but in reality, it is easier DOING it than it is writing instructions how to do it. Take it patiently, step by step:

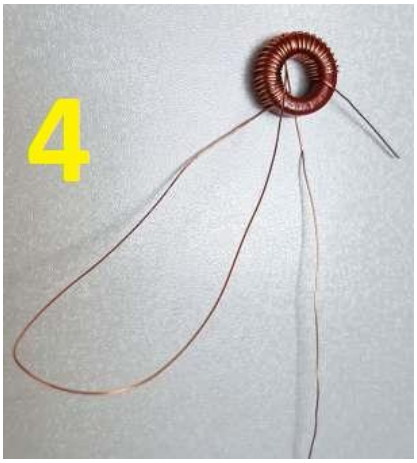
1) Hold the toroid between thumb and finger, and thread the first turn of the wire through from top to bottom. Leave about 3cm of wire at the free end.
2) Apply tension to the wire after each pass through the centre hole, to try to keep the windings tight and even. The wire turns should sit neatly side-by-side on the toroid, without overlapping.
3) Grip the toroid between thumb and finger as you wind.

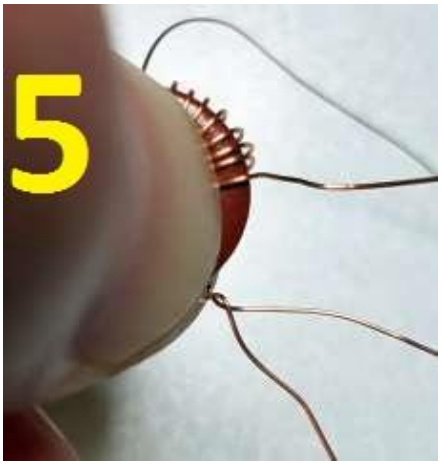


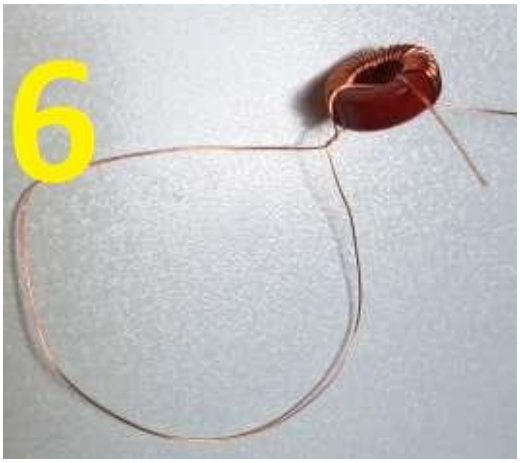




4) When you have completed 30 turns, pass the wire through the hole for the 31st turn but leave a large loop of wire between the 30th and 31st, without pulling it tight.
5) Grip the toroid and wound turns tightly between thumb and finger, and with the other hand apply some twists the wire loop, tight next to the toroid.
6) The result is a wire loop after 30 turns, as shown.





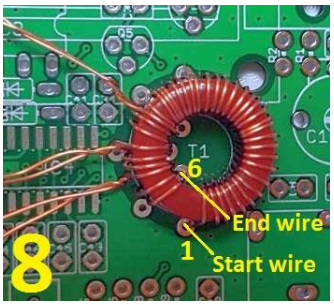


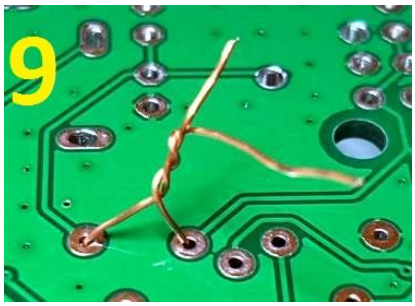
7) Do the same thing for two more loops, which are between the 33rd and 34th turns, and 36th and 37th turns respectively. It is easy to lose count. An easy way is after step 6, pass the wire through the hole 3 more times, and on the 3rd one, make a loop. Similarly count three more and make a loop on the third. Then finally three more turns to complete the

toroid's 39 windings. Count the windings to make sure you have 39. When you are sure everything is fine, cut the wire leaving about 3cm of wire free at the end.

8) **The remaining steps show the transformer installation on an otherwise empty PCB, to make the explanation clear.** Thread the original start of your winding (from step 1) into hole 1 in the diagram. Thread the final end of your winding (from step 7) into hole 6.

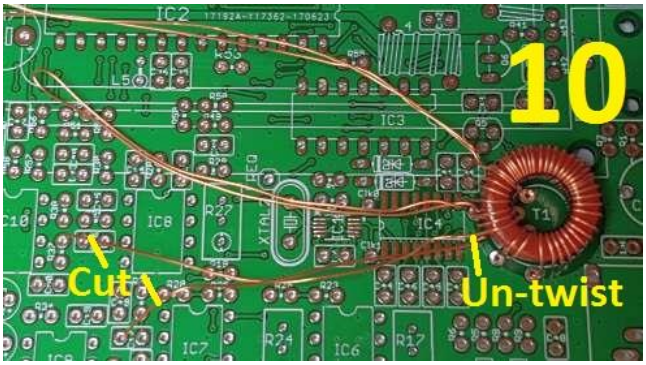
9) Twist these two wires under the board to keep the toroid in place while you deal with the remaining wires.

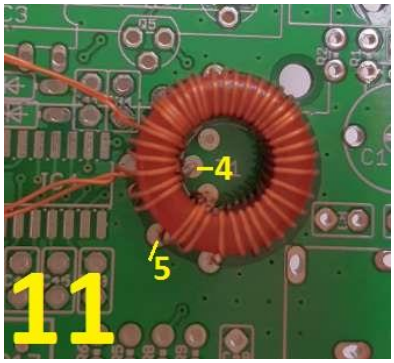




10) Now cut the 3rd loop (the one nearest the end of the winding work), and un-twist the twisted section you made near the toroid body.

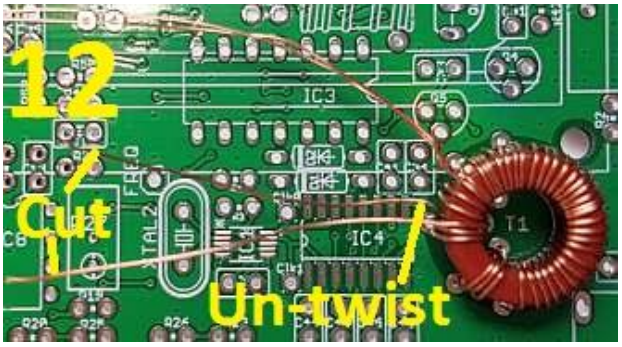
11) When you cut the loop, you therefore created two wires. One of these came over the top of the toroid, and you can easily verify that this is the one which has three turns through the toroid then passes through hole 6. So, insert this wire into hole 5. Once again to be clear: you should now have a winding of three turns (which is labelled "secondary 1", above), with one end inserted into hole 6 and one end inserted into hole 5.
The other wire came from UNDER the toroid. You must push this wire towards the toroid and pull it out through the centre hole of the toroid. Now thread it through hole 4.
Under the board, twist the two new ends of wire together to keep them in place.

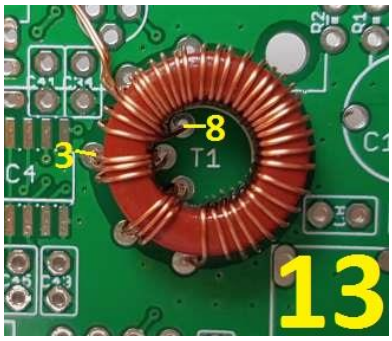




12) Next cut the 2nd loop, and un-twist the twisted section near the toroid body.

13) Similar to step 11; the wire which came over the toroid body has three turns then goes into hole 4, which you did in step 11. Insert this wire-end into hole 3.
The other wire end that came from under the toroid body should be gently pushed toward the toroid, and pulled up through the centre hole of the toroid. Insert that wire end into hole 8. So now you have the "primary" winding consisting of three turns, between holes 3 and 4.
Twist the two new wires under the board again, to keep everything in place.

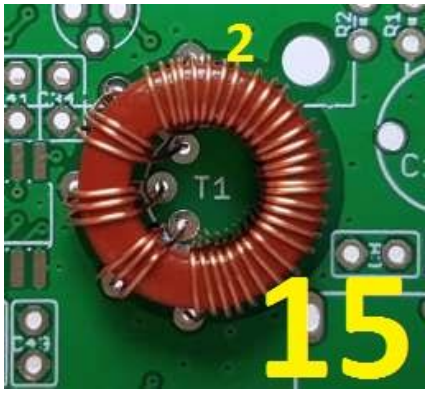


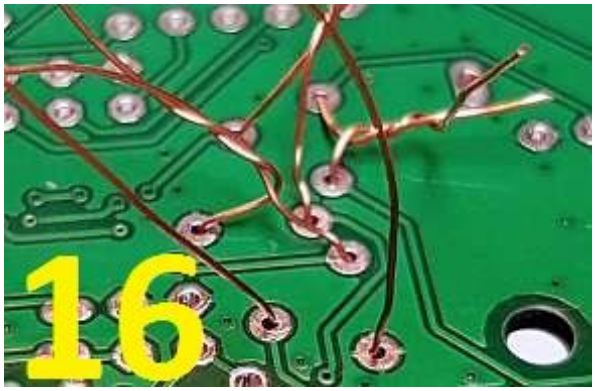


14) Finally, cut and un-twist the loop which you created first, which was between the 30th and 31st turns of the toroid winding. Push the wire which came over the toroid body, into hole 7. Now you have three turns of wire, which make up “secondary 2”, between holes 7 and 8.

15) The last wire came from under the toroid body when you cut the loop; this wire is the other end of the 30 turns “secondary 3” winding, so insert it into hole 2. It is already near to hole 2 and you don’t need to push it under the toroid body as you did in previous steps.
Take a moment now to review the situation. You should be able to identify the four windings of T1, and squeeze them together neatly as in the photo, to verify that each end of the 3-turn windings goes into the correct holes.

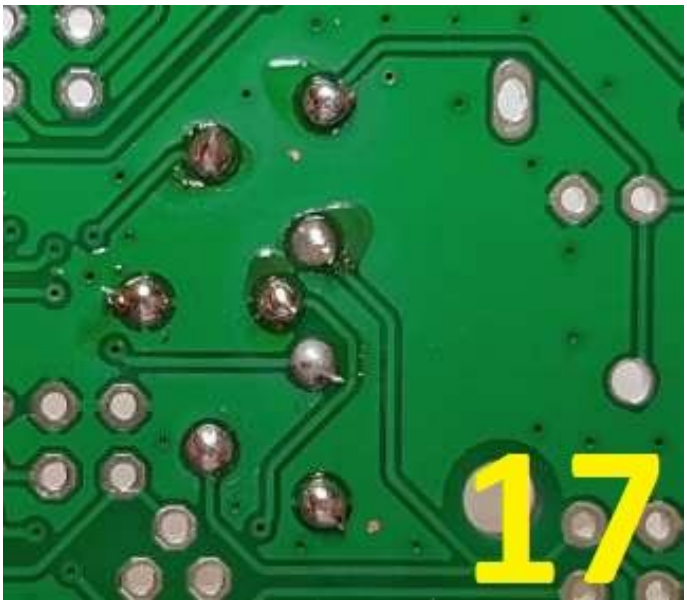
16) Under the PCB, you should have three pairs of twisted wires, and one pair (that you installed last), un-twisted.





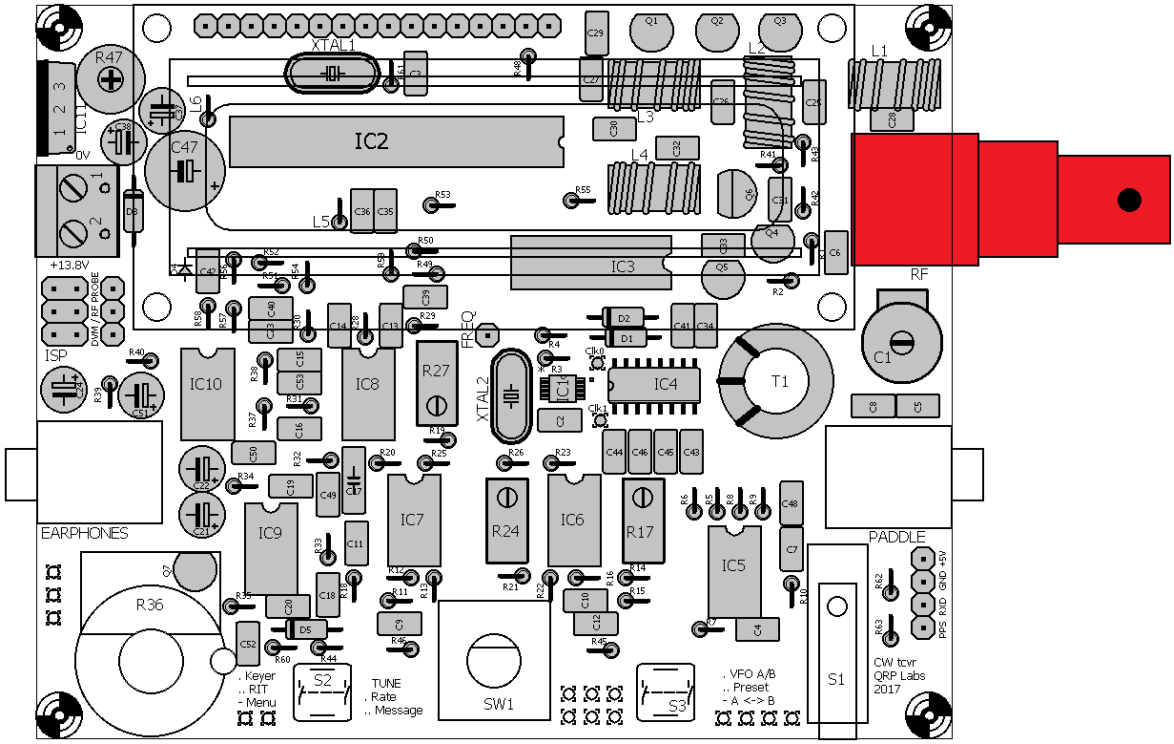
17) Now you can solder the eight connections under the PCB. I recommend doing one pair of wires at a time; this way, the other wires will hold the toroid in place and stop it falling out. Start with the two un-twisted wires. Pull each wire tight, bend it over at about 45-degrees, and cut it 1-2mm away from the PCB surface. Having bent the wire prevents it from falling out. Now solder the wire. Remember to hold the soldering iron to the joint for 10 seconds or so, to allow the enamel insulation to burn off.
Repeat for all the other wires, one pair at a time, until all eight are soldered. If you have a DVM, check for DC continuity (zero ohms resistance) across each winding. If you do not get the expected continuity, then it means either
a) you have not managed to scrape or burn away the enamel insulation properly so there is no electrical connection AND/OR
b) you put the wires into incorrect holes AND/OR
c) your expectation is wrong because you have not identified which pad on the PCB is labelled 1-8 in the diagram.

18) The final picture (18) shows the toroid installation completed.



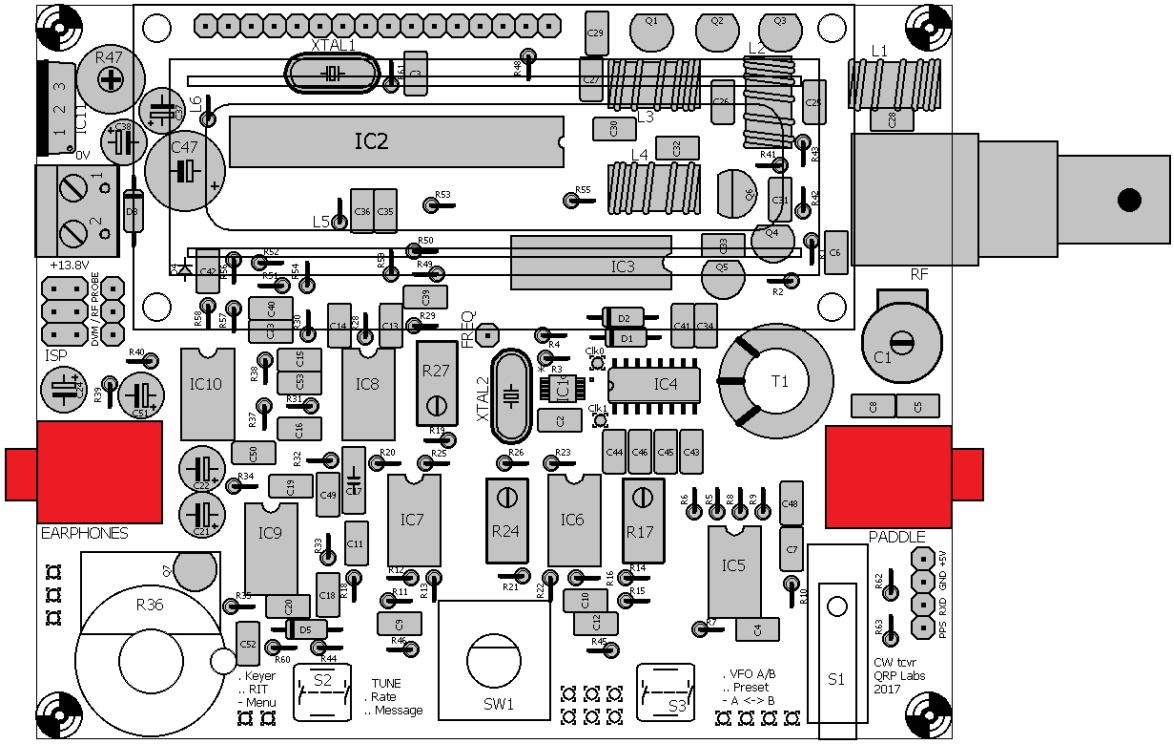
3.56 Install RF output BNC connector

Solder one pin first, to check that the alignment is correct; when happy, solder the remaining pins. The connector has RF and Ground connections, and two fat rods which are for mechanical stability only.



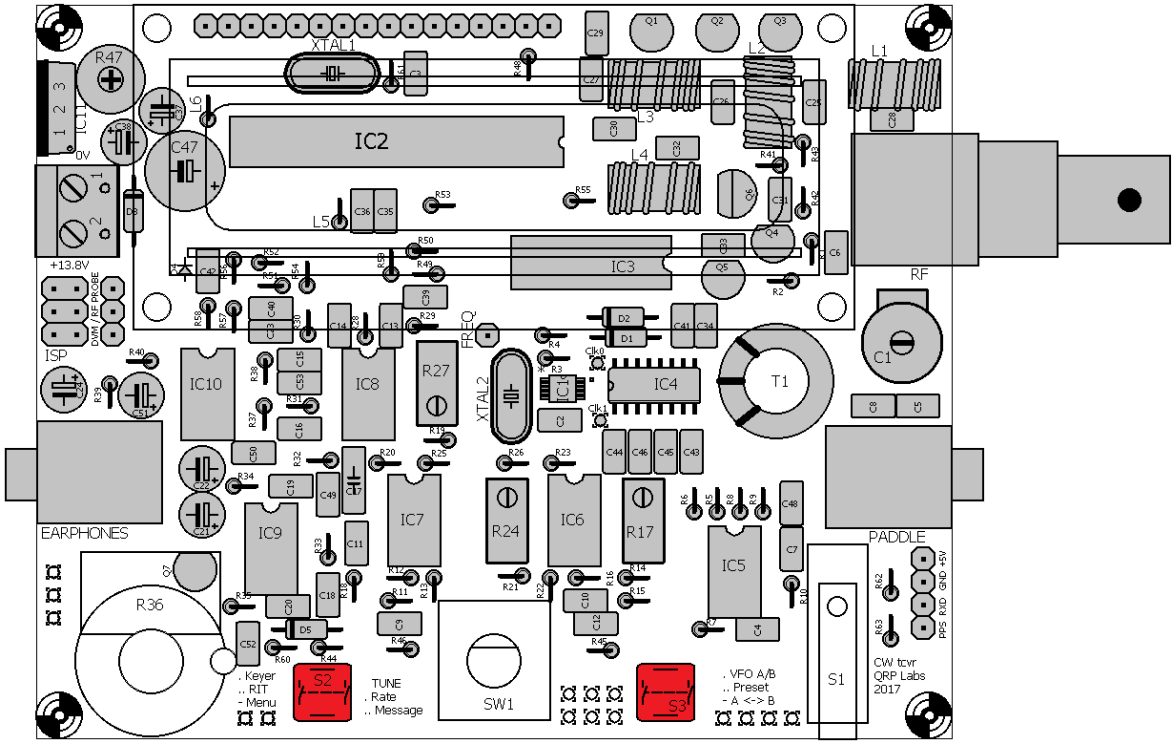
3.57 Install 3.5mm stereo connectors

These connectors are used for the audio output (earphones) and for optional connection of a paddle. The sockets are a VERY tight fit, but they DO fit, with care, eventually. When you are happy that the socket is neatly aligned and seated on the PCB, solder the remaining pins.



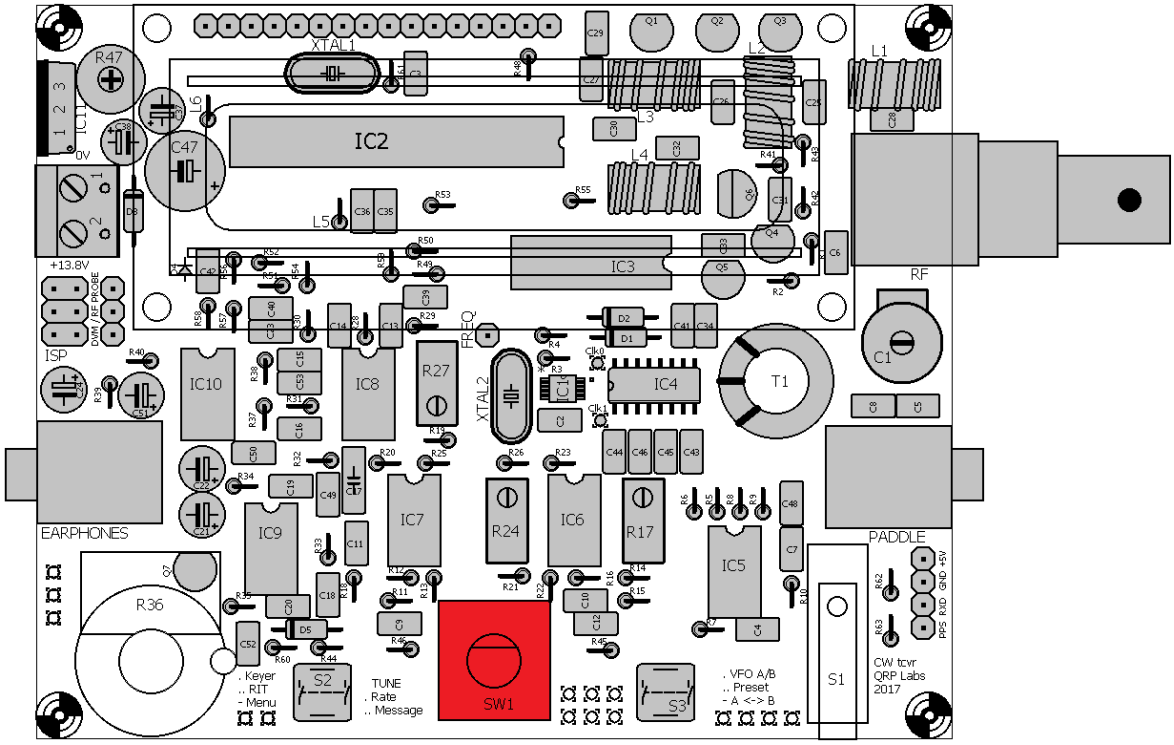
3.58 Install buttons S2 and S3 (left and right buttons)

These buttons (or other push-to-make buttons) may alternatively be wired off-board, for example when mounted in a front panel. Refer to later section for wiring details.



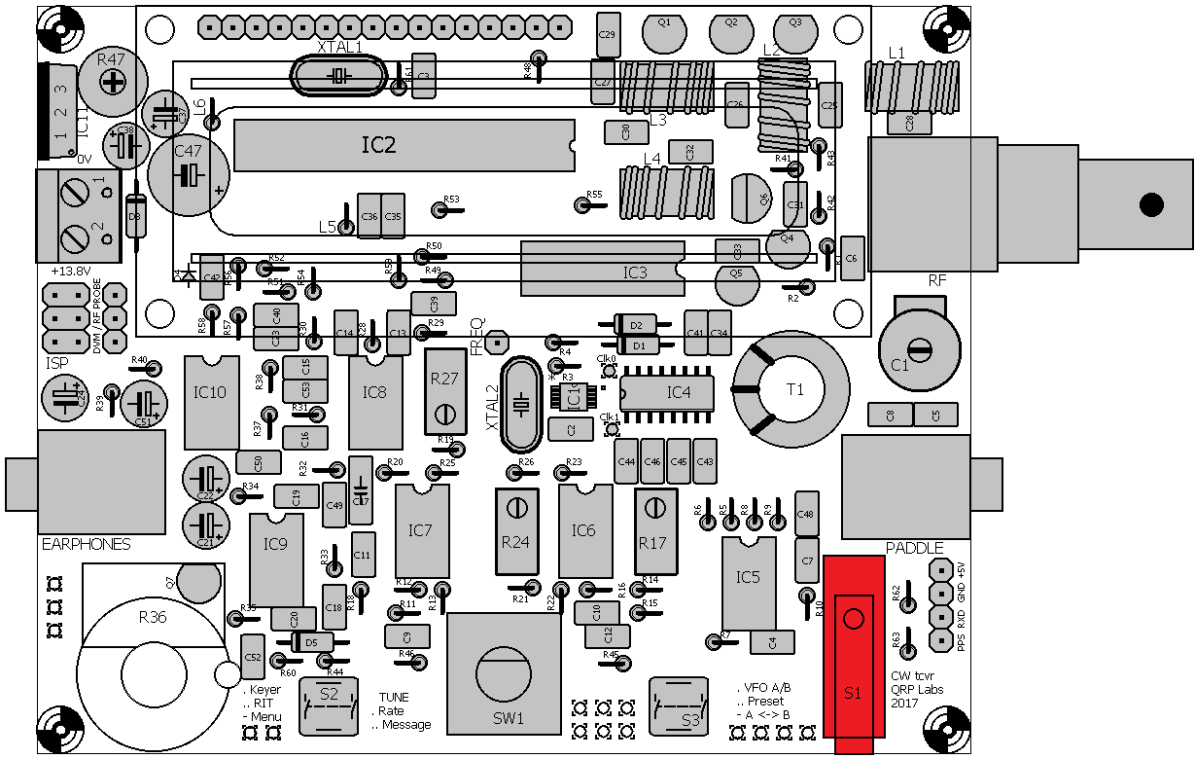
3.59 Install rotary encoder

This switch has seven solder pads: five are for electrical connections and the two large tabs are for mechanical stability. You may also choose to mount the switch off-board, for example on a front panel. Refer to the later section describing the wiring. Remember that it will be difficult to remove the switch later, so you may wish to make the external mounting decision now.



3.60 Install microswitch

The microswitch can be used as an on-board “straight key” if desired and is suprisingly effective! The PCB holes are large so be sure to use enough solder to make good joints.



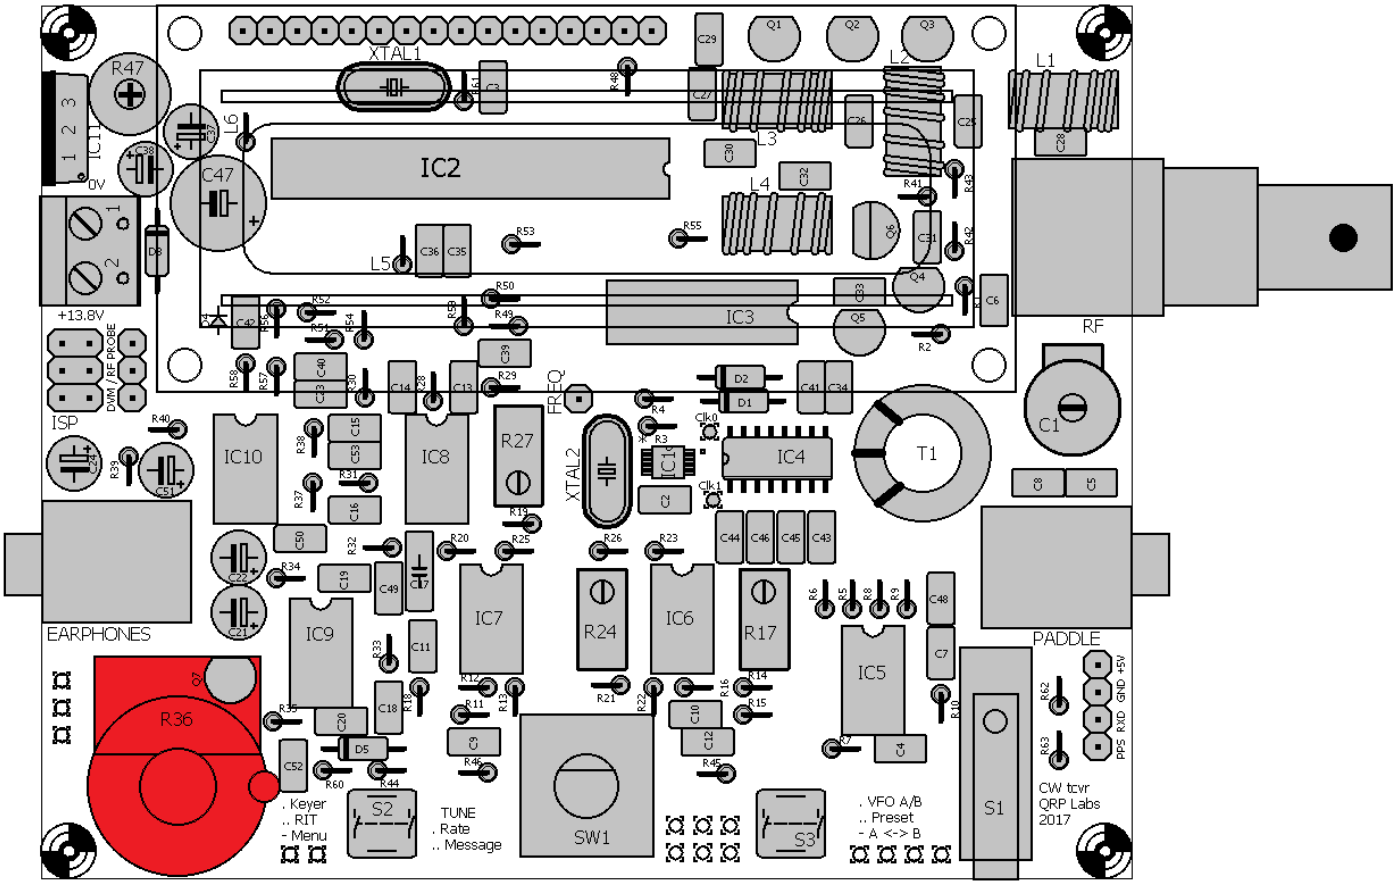
3.61 Install gain control potentiometer R36

Carefully bend the pins of the potentiometer upwards 90-degrees as shown in the photograph.

Remove the nut from the potentiometer, fit the shaft through the hole in the PCB, and carefully install the bolt and tighten with pliers. There is an anti-rotation tab on the metal case, which fits in the smaller hole to the right of the main shaft hole. The tab hole is near to C52, on the right of the potentiometer. When tightening the nut ensure that the pins remain aligned with the corresponding pads on the PCB.

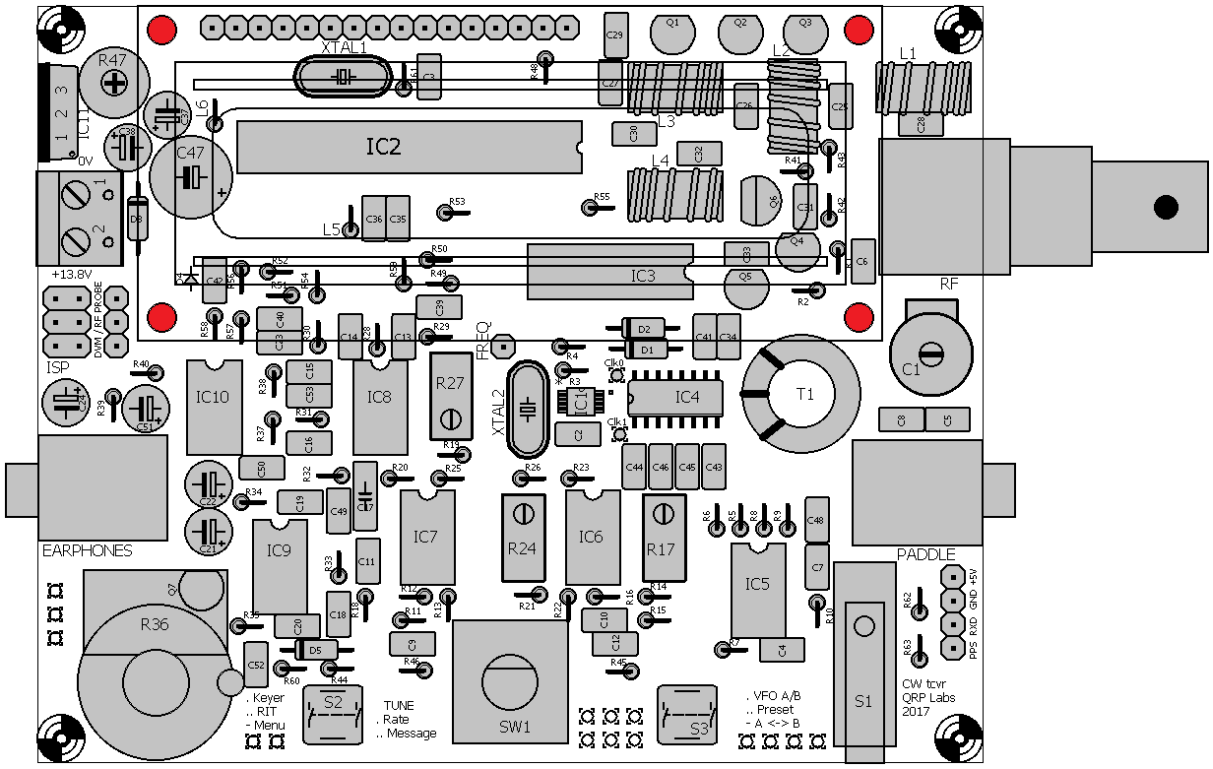
Be very careful with this potentiometer and do not over-tighten the nut. The potentiometer is quite delicate.

The three pins do not extend far enough to fit into the three corresponding holes on the PCB. However they are close enough that a generous blob of solder is enough to make a reliable connection to each pin.



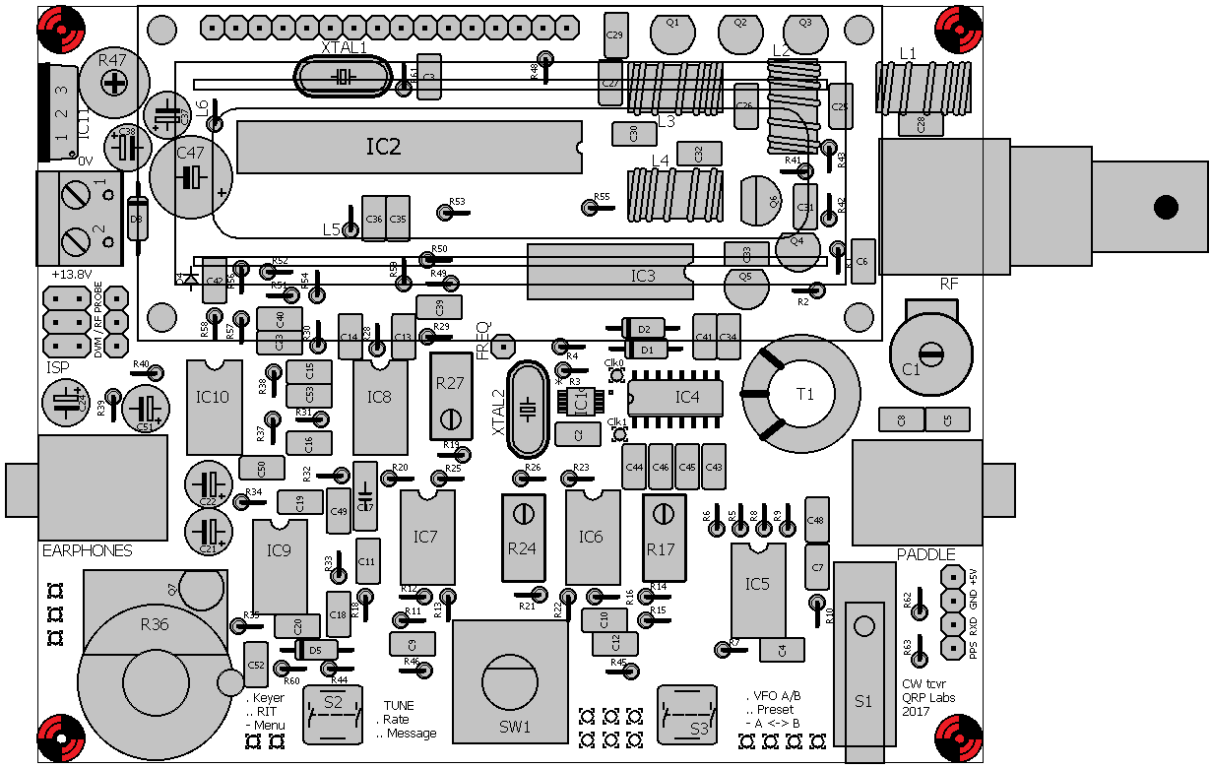
3.62 Install four 12mm hex spacers at the LCD corners

Install the four 12mm spacers on the top side of the PCB, threading four M3 nylon screws through from the underside of the PCB. These four spacers fix the LCD module to the PCB assembly.



3.63 Install four 12mm hex spacers at the PCB corners

These spacers are installed on the bottom side of the PCB, with the four M3 screws threaded through from the top (component) side. These four spacers make four little “pillars” at the board corners, to keep the underside suspended above your workbench or fixing to an enclosure.



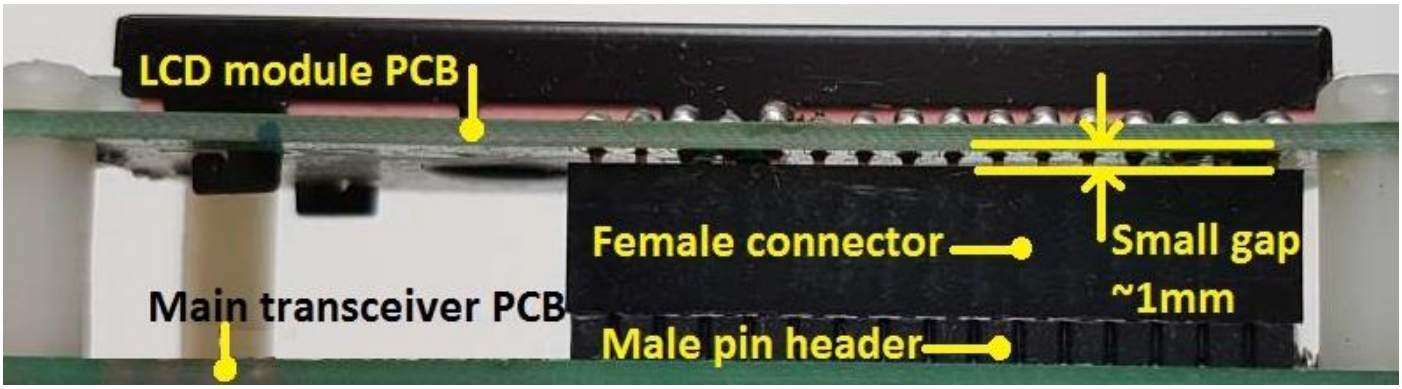
3.64 Install knobs

Two black knobs are supplied, one for the rotary encoder and one for the gain control. When fitting the gain control knob, you should ensure that when the potentiometer is turned all the way anti-clockwise, the white pointer on the knob points to the bottom left corner of the PCB. This is the conventional alignment for volume control knobs.

3.65 Install 16-pin female connector on LCD module

The 16-pin female header connector must be installed on the solder-side of the LCD module, so that it will mate with the 16-pin male header on the main transceiver PCB. The easiest way to do this is to temporarily assemble the modules and bolt the LCD in place using the supplied nylon M3-sized screws.

The nylon headers at the LCD module corners are a little longer than would be ideal. Accordingly leave a small gap between the 16-pin female header connector, and the LCD module itself. Push the female header connector all the way onto the 16-pin header on the main PCB, and solder the pins in place.



3.66 Install microcontroller

Finally install IC2, the programmed ATmega328P microcontroller. Be very careful to ensure that the dimple on the chip is aligned with the dimple on the 28-pin DIP socket, which itself should already be aligned with the dimple on the PCB silkscreen.

3.67 Install LCD and the remaining 4 screws to bolt LCD module

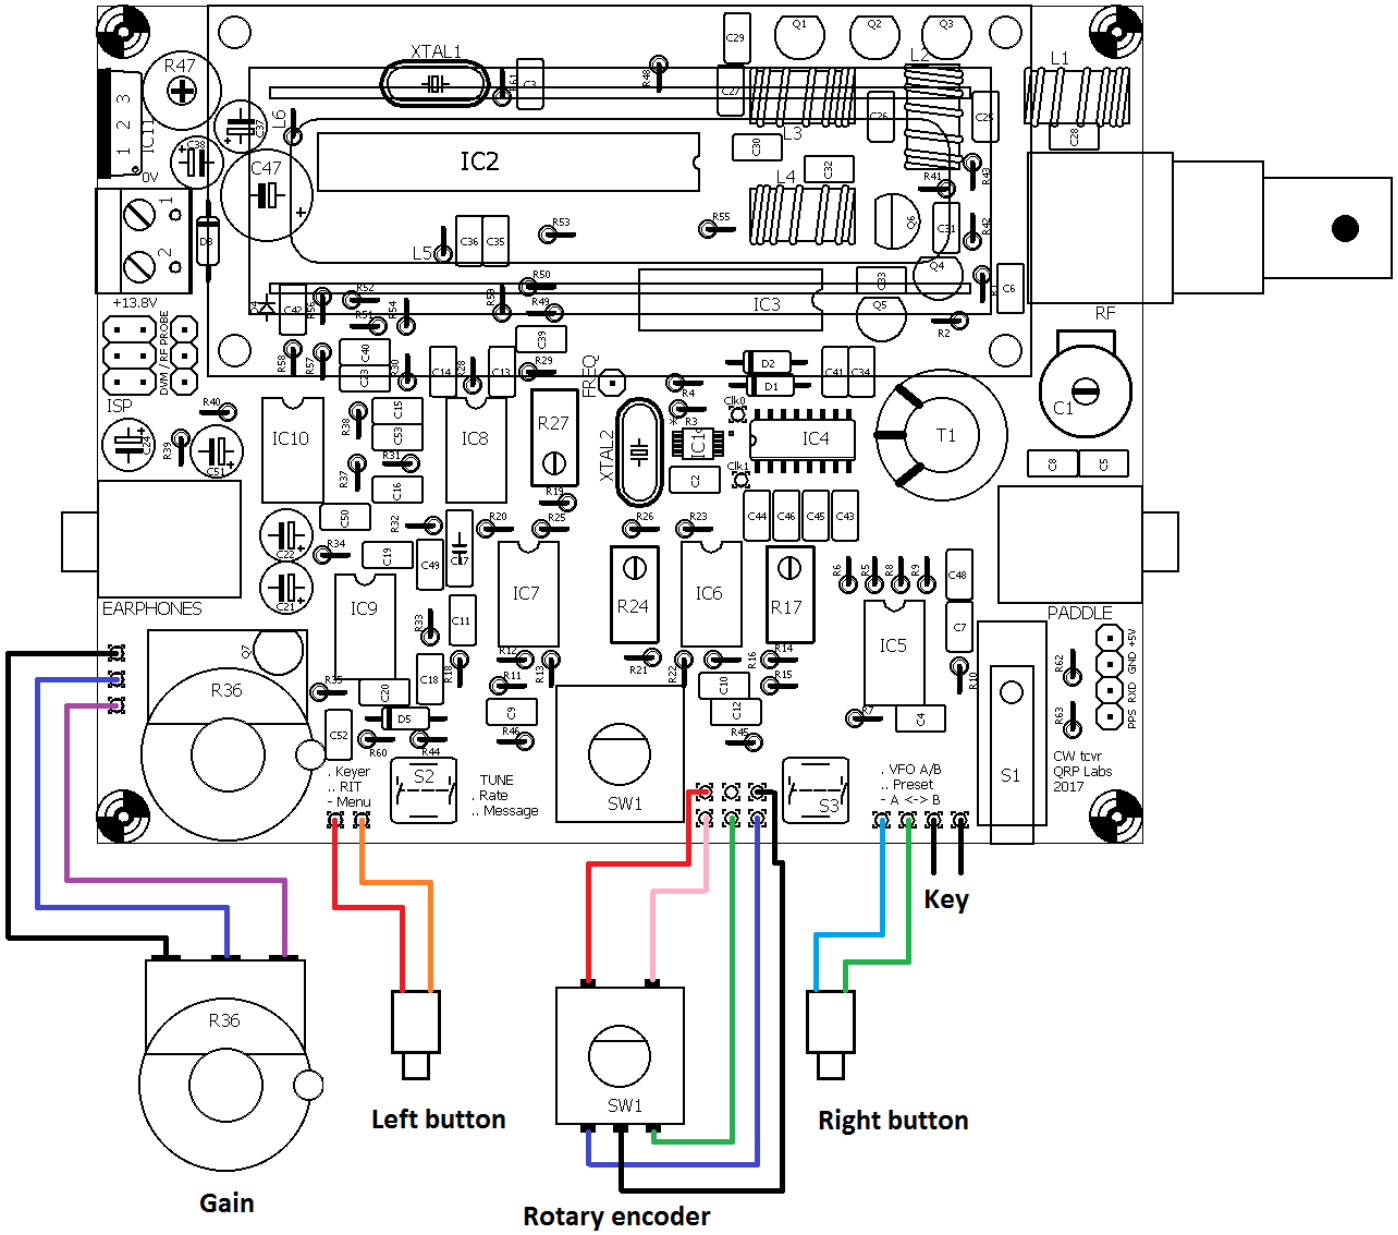
Now plug in the LCD module and screw it in place, using the remaining 4 nylon M3 screws.

3.68 Connections for off-board mounting of controls

The following wiring diagram shows the connections between the PCB pads and controls (buttons, rotary encoder, gain potentiometer) that should be made if you intend to wire the controls off-board. For example, you may wish to install the radio in an enclosure and mount the controls on a front-panel.

The diagram shows the two buttons, gain potentiometer and the rotary encoder. PCB pads are also available for the microswitch “Morse key” as labelled in black (bottom right) but typically you would probably wish to plug a key or paddle in to the 3.5mm socket.

If installing the radio in an enclosure you would also want to wire the LCD module to the PCB rather than plug it in directly. Take care to ensure short cables, or use shielded (screened) cable in order to avoid radiating digital noise into the RF circuits.



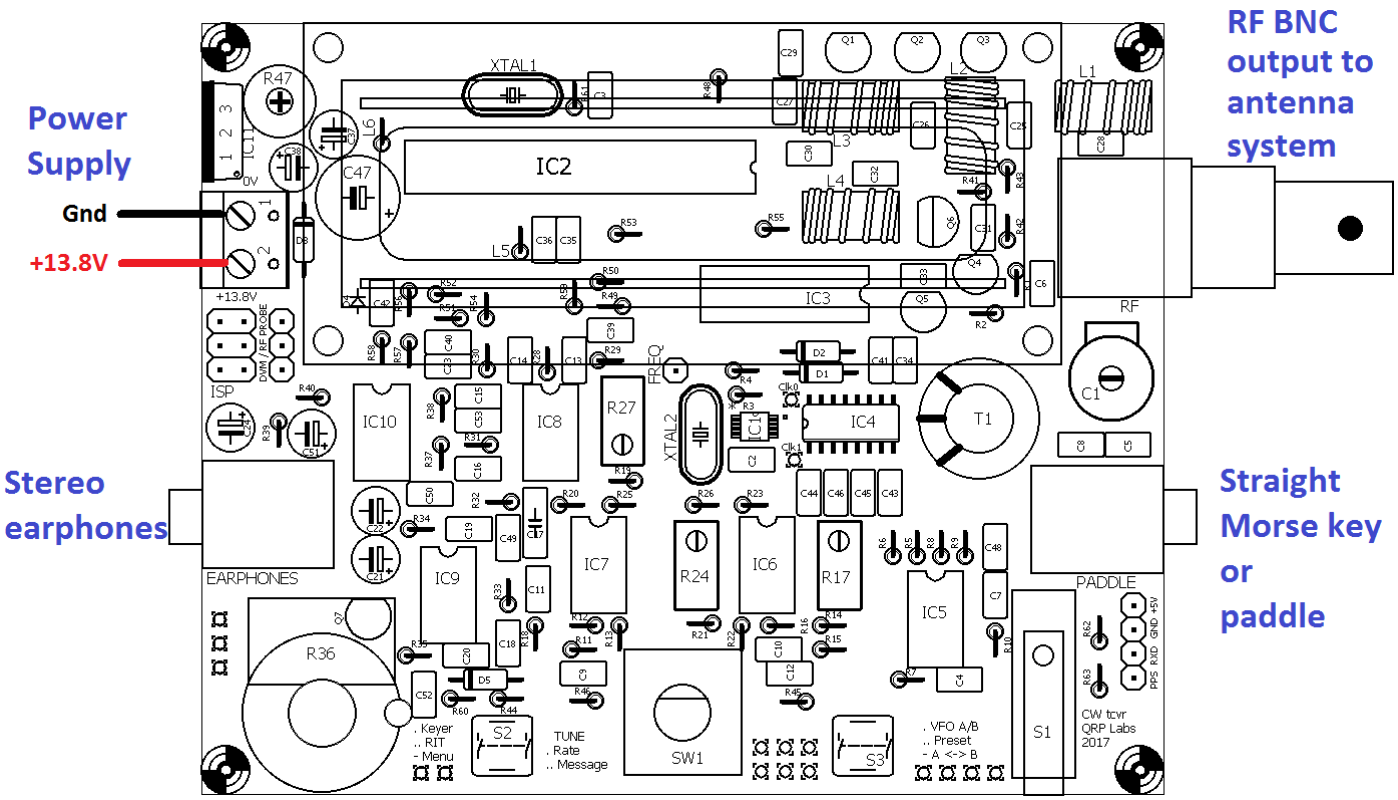
3.69 Connections for basic operation

The following diagram illustrates the basic connections for transceiver operation. A power supply is required, which needs to be able to supply up to 0.5A on transmit. The supply voltage may be from 7 to 16V, and the RF power output will depend on the supply voltage (higher output power is produced at higher supply voltages).

Note that the 7805 voltage regulator requires no heatsink; however the heat production will increase as supply voltage is increased, and the IC does get uncomfortably hot to touch at 16V supply. Although I still do not believe it is necessary, you may feel less disturbed if you fit a small heatsink to the 7805 voltage regulator if you intend to operate at higher supply voltages.

The earphones can be any stereo earphones such as commonly used with audio equipment, mobile phones and so on.

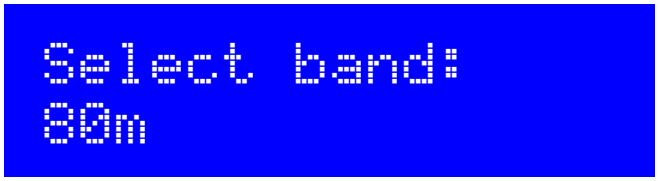
The RF output is a filtered 50-ohm output for connection to a usual antenna system (antenna, and matching unit if applicable).



3.70 Adjustment and alignment

The first thing that you will notice when you apply power to the radio, is that there is probably nothing at all shown on the display. This is because you need to adjust the contrast trimmer potentiometer R47 at the top right of the PCB! Adjust it with a screwdriver until the display text looks right to you.

You should now see the following text on the display:



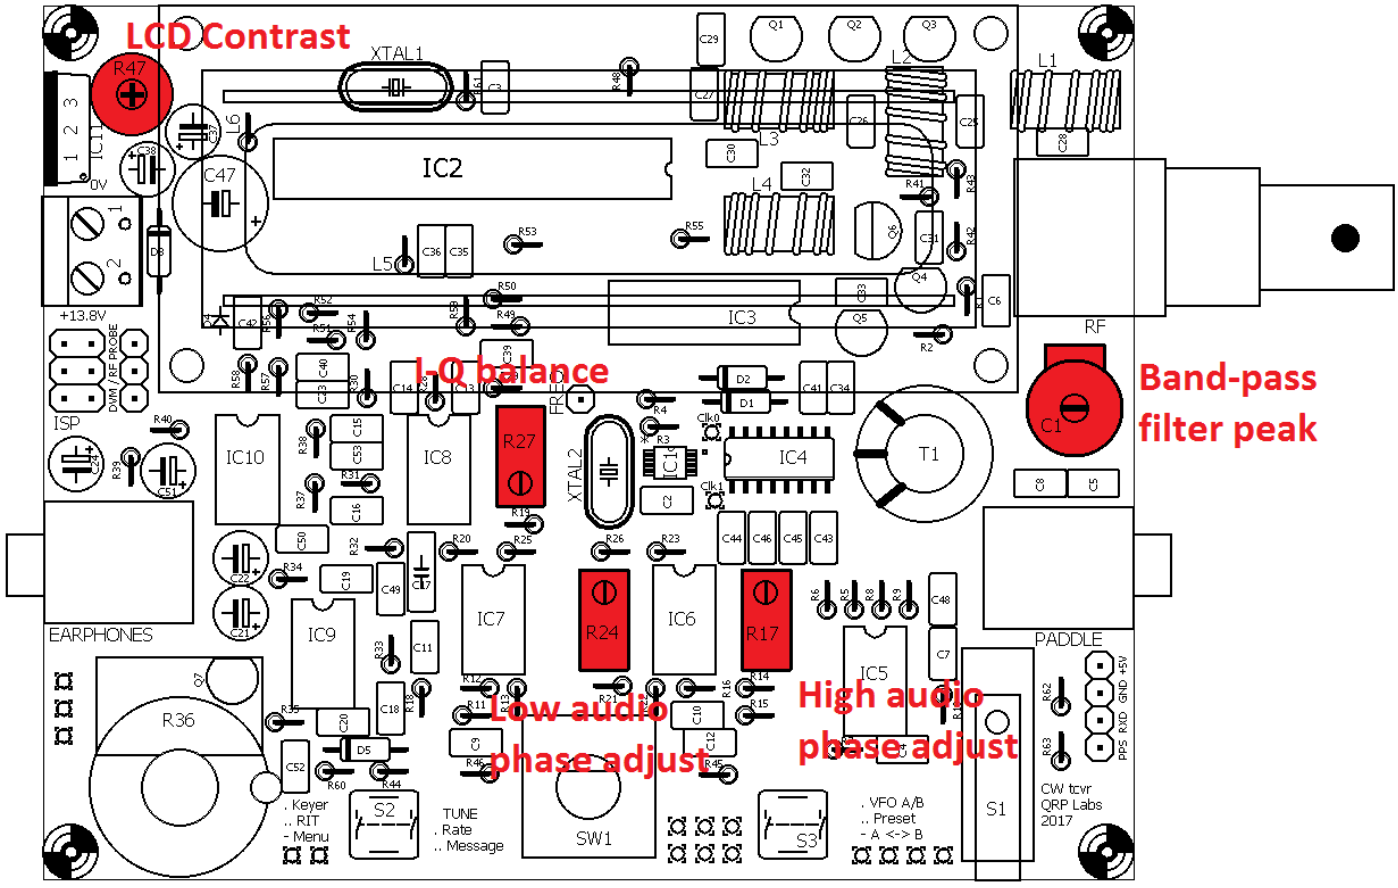
Turn the rotary encoder knob to select the band you have built the kit for. Then press the small button to the left of the rotary encoder, to make your selection.

There are four more adjustments which now need to be made as part of the alignment procedure. The adjustments are:

- Band-pass trimmer capacitor peaking, C1
- I-Q amplitude balance, R27
- Audio phase shift adjustments, R17 and R24

Until these are adjusted, the sensitivity of the radio will be very low. So, do this first, before going any further!

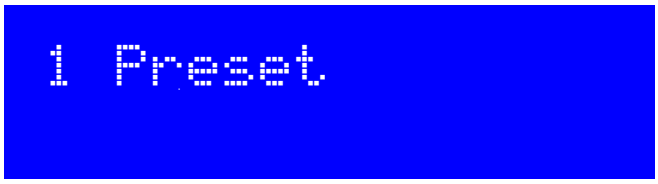
The location of these five adjustments is indicated on the following diagram.



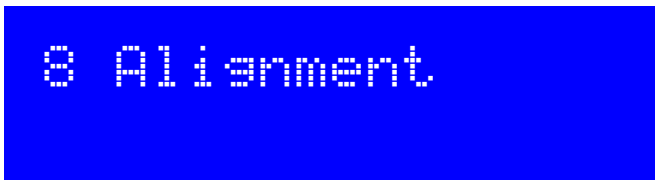
In summary: the alignment tools built into the radio consist of a signal generator which injects a signal into the RF front end, and digital signal processing which adds a 250-Hz digital filter to the existing 200Hz analogue filter, and calculates the amplitude of the signal detected in that bandwidth. During alignment, the amplitude is displayed on-screen as an intuitive bar across the bottom row of the display. Using a screwdriver, you adjust the trimmer component in order to maximise or minimise the displayed amplitude.

Unplug the antenna during alignment of the radio!

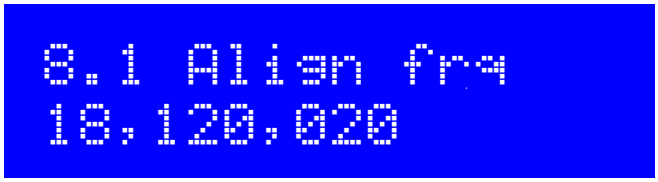
First adjust the band-pass trimmer capacitor C1. To do this, give one long press to the left button. The screen now displays the first menu category:



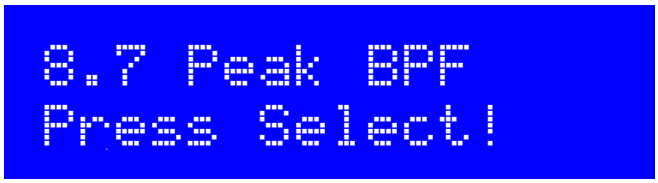
Turn the rotary encoder until you see the alignment menu:



Now press the left (“select”) button, to enter the alignment menu. For example, for 17m operation, the alignment frequency menu item should already be set to a frequency in the CW section of 17m, as follows:



Now turn the rotary encoder until you see:



Do as it says! **But if you have earphones plugged in, please take them out of your ears first.** The tone will be very loud. Press the left (“select”) button to switch on the signal generator so you can adjust the C1 trimmer potentiometer. Now if you have earphones plugged in (and lying hopefully, on your bench), you will hear a loud tone at 700Hz. The display will look like this photograph:

Adjustment of the C1 trimmer capacitor should change the size of the amplitude bar. You need to adjust the C1 trimmer for MAXIMUM amplitude. When this is done, the peak of the band pass filter will be centred on the CW section of the band.

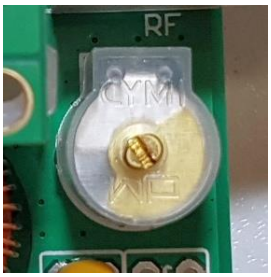
It is very important to understand the number at the top right of the LCD, here shown as 09. This is an amplitude scaling factor, expressed as a power of 2. In this example, the actual amplitude is divided by a factor of 512 (2 to the power of 9) then displayed on the screen. In this photograph, 27 little vertical bars are shown, which means the actual measured amplitude value is 13,824.

If the displayed bar drops below one third of the width of the LCD, then the division factor is reduced by one and the bar is re-displayed. On the other hand, if the displayed bar overflows the right edge of the screen, the division factor is increased by one. This simple method creates an auto-scaling display of the amplitude.

Therefore, to peak the band pass filter trimmer, first adjust the trimmer potentiometer while looking at the division factor in the top right of the LCD. Then carry out the fine adjustment using the displayed amplitude bar. The peak is quite sharp.

Be wary because there can be more than one peak (more than one response of this simple band pass filter). So, tune the trimmer capacitor through its whole range, and determine the maximum scaling factor that you see. In my case here, it is 09. Then make the very fine adjustment necessary to peak the amplitude bar.

When you have peaked the response, check carefully that the C1 trimmer capacitor is not at either end of its range. If it is, this means the resonant circuit is NOT correctly peaked. You need to adjust the number of turns on the long secondary winding of the T1 transformer. Visual inspection will show clearly whether or not the trimmer capacitor is at the end of its range.



Perfect!

OK! The plates of the trimmer capacitor are somewhere nicely in the their range, not at the minimum or maximum capacitance. You have found the peak response of the BPF and all is well.

Plates completely closed

Here the fixed and movable sets of capacitor plates are completely meshed, resulting in the highest capacitance. It means MORE inductance is needed. So carefully unsolder one end of the secondary 3 winding of T1, join a piece of wire, and wind it 5 more turns through the toroid. Then try again. Don't worry if it looks a bit messy.

Plates completely open

Here the fixed and movable sets of capacitor plates are completely unmeshed, resulting in the lowest capacitance. It means LESS inductance is needed. So carefully unsolder one end of the secondary 3 winding of T1, remove 5 more turns through the toroid, and resolder. Then try again.

Adjustment of I-Q balance

Now turn the rotary encoder “one click” clockwise to measure I-Q balance.

Note that the previous alignment used the audio signal BEFORE the final amplification stage, so the gain control had no effect on the signal level. In contrast, the I-Q balance and audio phase shift adjustments use the audio signal AFTER the audio amplification stage. This is necessary because these alignment adjustments inject a signal into the opposite (unwanted) sideband, and the signal level is much lower, therefore it needs to be amplified for the microcontroller to be able to measure it accurately. In this case therefore, the gain control DOES now have an effect. I suggest adjusting the gain control approximately to mid-way to start with. This will provide enough gain, yet not so much gain that the amplifiers are driven into overload, which distorts the signal and measurements.

You should try to carry out the adjustments with the measured audio values in the range 5 to 10 (as indicated by the division ratio in the top right of the display). If it reaches 12, the operational amplifiers are limiting, clipping the signal which will make it difficult or impossible to make the adjustment accurately. If the displayed value (top right of the display) is only 2 or 3, that indicates the gain is too low. Therefore, adjust the volume control so that the display is something like 9.

The I-Q trimmer potentiometer is R27. It is a multi-turn trimmer potentiometer so it may need to be turned quite a few times to get to the optimum value! For this adjustment, you are looking for the MINIMUM amplitude, not the maximum we adjusted the BPF trimmer to. We adjust for minimum because now the injected signal is measuring the unwanted sideband. We want to MINIMISE the unwanted sideband level.

Adjustment of 90-degrees audio phase shift

Similarly turn the rotary encoder one more “click” clockwise, which automatically sets the unwanted sideband audio signal to appear at 600Hz, and adjust the “low audio phase shift” trimmer potentiometer, R24. Again, adjust it for MINIMUM signal.

Turn the rotary encoder clockwise one more “click” and adjust the “high audio phase shift” trimmer potentiometer R17, again for minimum signal.

Now it is necessary to go back and forth between these three menu items for minimum unwanted sideband:

- 8.8 I-Q Bal (adjust R27)
- 8.9 Phase Lo (adjust R24)
- 8.10 Phase Hi (adjust R17)

This is because to some extent, these adjustments influence each other. Obtaining the optimum set of adjustments is an iterative process. So, turn the rotary encoder a click at a time anti-clockwise or clockwise, back and forth through these three menu items. Each time make small further adjustments to the appropriate trimmer potentiometer and observe the lower amplitude. Keep doing this until you see that you cannot really manage to get the unwanted sideband any lower in any of those adjustments. Pressing the right (exit) button twice leaves the menu system and returns the radio to normal operation.

Other items in the alignment menu relate to the calibration of the 27MHz reference oscillator of the synthesiser, and the 20MHz system clock oscillator of the microcontroller. These adjustments can be made manually, or by connection of a GPS module such as the QRP Labs QLG1 GPS receiver kit. However, since this calibration is a lot less urgent than the Band Pass Filter peaking and

unwanted sideband cancellation, they are left until the description of these menu items in the operating manual.

Following the adjustment of these alignment trimmers, the radio is ready to use. A lot of settings are available in the configuration menu, and you should read the operation manual to understand and make use of all the features!

4. Operating instructions

4.1 Overview of features

This 5W CW transceiver kit includes a large number of features defined by the firmware in the ATmega328P microcontroller chip. The following is a brief summary of the features to explore and enjoy. Read the subsequent sections for more detailed information on these features.

Synthesised VFO with rotary encoder tuning

The VFO is an Si5351A Synthesiser chip, configured by the microcontroller. A rotary encoder tunes the VFO, with a variable tuning rate. The radio includes two VFOs, A and B. You can swap from one to the other, copy the contents of the active VFO to the inactive one, or operate Split (Transmit on VFO A, receive on VFO B). There is also a RIT mode offering a receive offset of up to +/- 9,999Hz. The CW offset is also adjustable, and CW-R (sideband swap) mode is supported.

Memory features

There are 16 frequency presets for your favourite operating frequencies. Each frequency preset can be edited in the configuration menu, or loaded/saved into/from the currently operating VFO.

Message mode

The firmware supports storage of 12 messages. Four of these are 100 characters long, the other eight are 50 characters long. A single button click shows the list of messages to send. Message sending can be configured to send just once, or a configurable number of times, or indefinitely repeating. The interval between transmissions is also configurable. The message feature can be useful, for example, for setting up a repeated CQ call with a pause between repeats, during which you can listen for any answers. As soon as you touch the key to begin transmitting, the automatic message mode is cancelled.

CW Keyer

There is an onboard microswitch which can be operated as a “straight” (traditional) Morse key. The firmware also includes an Iambic keyer, for connection of a paddle. The keyer can be configured to operate in Iambic modes A or B, or Ultimatic mode. The keyer speed is variable both from the configuration menu and via a single button press during operation.

With its solid-state, microcontroller operated transmit/receive switch, the radio can operate in full break-in “QSK” mode, or if you prefer, semi-break in.

CW Decoder

A CW decoder operates in the chip. This can be useful on air, particularly for newcomers to CW, though it is never anywhere near as good in QRM or weak signal conditions as a good CW

operator using the wet-ware between his ears. The decoder has a “Practice” mode too, for you to practice your CW sending without actually generating RF. The decoder can also be used to conveniently enter text in the message storage, or for configuration of any of the other menu items. The decoder can also be switched off if desired.

CW or WSPR Beacon mode

A beacon is included too, and this can be configured to operate in CW mode or WSPR mode. Owners of the QRP Labs Ultimate-series weak signal mode transmitter kits will be familiar with the operation of WSPR. A GPS module such as the QRP Labs QLG1 GPS receiver kit can optionally be connected to this CW transceiver kit to provide frequency and time discipline, as well as setting the Maidenhead locator (from latitude and longitude) that is encoded in the WSPR message.

S-meter and Battery voltage

An S-meter and battery voltage indicator can be enabled for display on the LCD. These are both configurable to your needs. The battery voltage indicator would be useful if you intend to operate the radio portable on battery power.

Built-in alignment tools

One of the nicest features of this CW transceiver kit, is the built-in alignment tools menu. The radio can act as its own signal generator, injecting an appropriate signal into the receiver front end, then measuring the audio amplitude after single-sideband demodulation. The menu items allow you to easily peak the Band Pass Filter adjustment, and to adjust the I-Q balance and audio phase shift adjustments for best unwanted sideband cancellation.

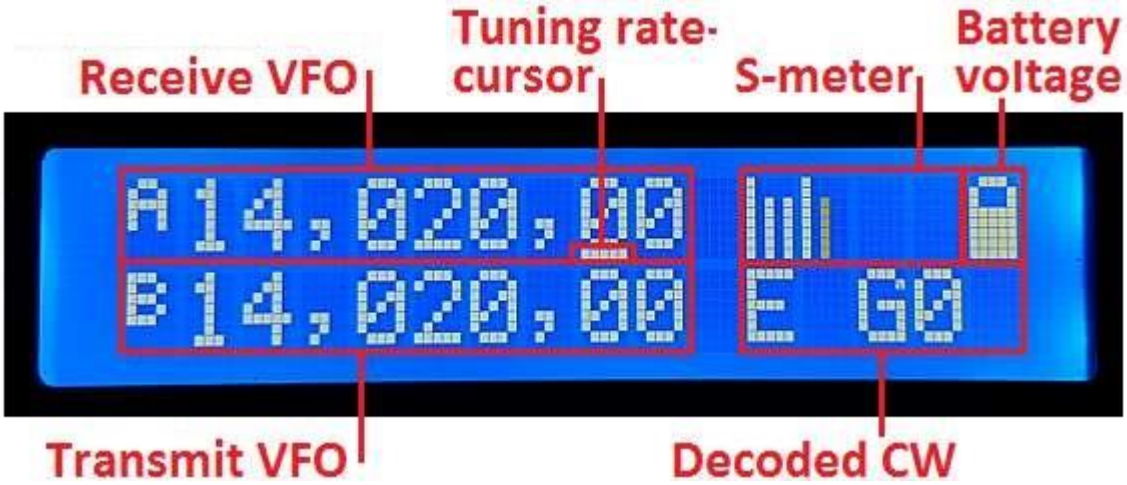
Built-in test equipment

For those times when the assembly didn’t quite go as well as we hoped, and we need to do some debugging – the radio includes its own suite of test equipment too! None of these items of test equipment are going to replace a $100,000 lab any time soon – but they provide very useful measurements for helping people without much test equipment, to debug the radio. They can even be used for testing other projects too!

- Voltage meter
- RF Power meter
- Audio channel amplitude measurements
- Frequency counter (0 to 8MHz)
- Signal generator (3.5kHz to 200MHz)

4.2 Display elements

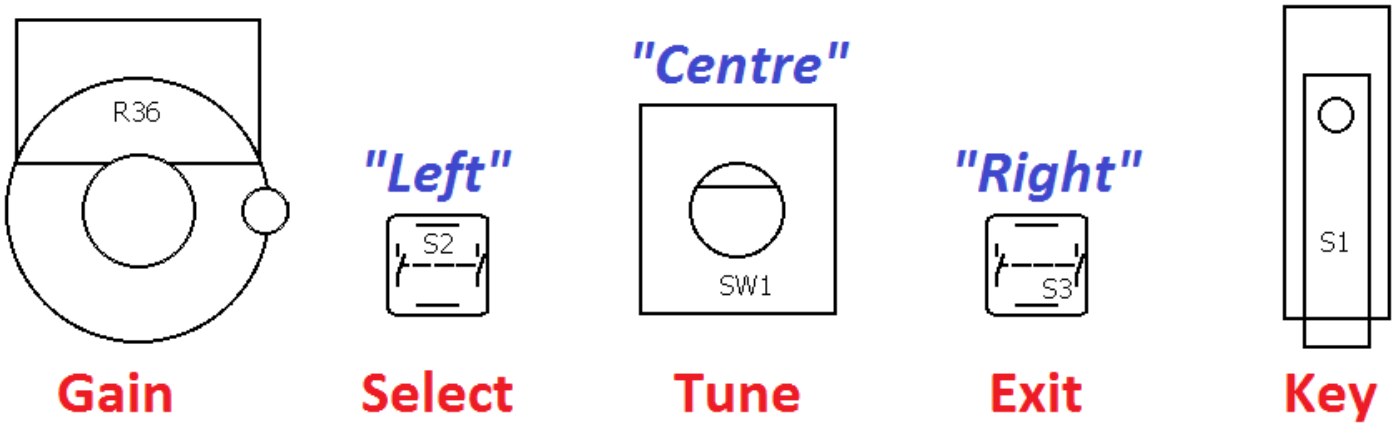
The kit uses a 2 row, 16 character LCD module with a blue backlight.



The main display layout during ordinary operation (which will be called “main operating mode”) is shown in the above photograph. The display during beacon or message transmission modes, menu editing, alignment etc. differs. The main display elements are as follows:

- The receive VFO frequency is always displayed, to 10Hz resolution, at the top left. This may be VFO A or VFO B. The nominally 700Hz CW offset is automatically applied. Ordinarily this frequency is also used for transmission.
- Tuning rate cursor: the underline appears under the digit which is currently tuned by the rotary encoder. In this example, the tuning rate is 100Hz per click, because the cursor is under the 100Hz digit.
- S-meter: these 4 characters display a basic (and not calibrated) S-meter. The scale is configurable (see later description). The S-meter may be shown or hidden.
- Battery voltage: a battery icon appears to indicate the battery voltage in 7 user-definable steps: from full to empty and 5 steps in between. It may also be shown or hidden.
- Transmit VFO: in SPLIT mode, the transmit VFO is displayed on the bottom row of the display.
- RIT (Receiver Incremental Tuning): when not in SPLIT mode, and when the RIT is non-zero, the RIT value is displayed in the bottom left (where the photo shows the VFO B frequency). When RIT is non-zero, and when not in SPLIT mode, the reception frequency is the transmit VFO frequency (which may be VFO A or B) plus the RIT (which may be a negative offset).
- Decoded CW: The remaining space on the bottom row is used for displaying the decoded CW text. When RIT is zero, and you are not operating SPLIT, the whole 16 characters of the bottom row are used for the CW decoder display. However, it may be hidden if desired.

4.3 Operator controls



This diagram shows the operating controls of the radio. All of the controls except the Gain potentiometer have multiple functions, depending on the operating mode, menu editing, etc. The tuning rotary encoder in the centre has a button on its shaft that is activated by pressing it, and this button also has multiple functions.

In this document, the three buttons are mostly referred to as “Left”, “Centre” and “Right”. The original names of the left and right buttons, “Select” and “Exit” respectively, refer to the common actions during configuration menu editing. Select edits a menu item or steps down into a sub-menu; Exit saves an edited menu item or backs up to the parent menu.

It is well worth remembering while you are familiarising yourself with the operation of the radio, that if you get into any unexpected function or menu – you can nearly always press the right (exit) button to cancel and get back to the main operation mode.

Each of the buttons (left, centre, right) may be pressed once, pressed twice (a double-click) or pressed for a long-hold. This facilitates three different functions for each button. In practice, the centre button is stiffer and it is difficult to achieve a double-click; therefore the centre button double-click has no function.

4.4 Tune rate

The rotary encoder tunes the active VFO. The rate of tuning is indicated by the underline cursor. In the example below, the underline cursor is under the comma between the 1kHz and 100Hz digits. This means the tuning rate is 500Hz.

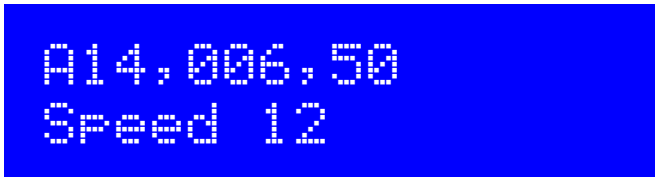
The available VFO tuning rates are 1kHz, 500Hz, 100Hz or 10Hz.

A press of the centre button (in the rotary encoder shaft) causes the tuning rate to change, in the cycle 1kHz -> 500Hz -> 100Hz -> 10Hz -> 1kHz etc.

The default tune rate up at start-up is a configuration item in the VFO menu (see later).

4.5 Keyer speed

The default keyer speed (in words per minute) at start-up is a configuration item in the Keyer menu (see later). During operation of the radio, the keyer speed can be easily adjusted. Click the left button once, and the speed will be displayed on the screen:



Now you can adjust the speed using the rotary encoder. Press any button to return to the main operating mode.

4.6 RIT

RIT (Receiver Incremental Tuning) allows the receive frequency to be adjusted while the transmit frequency (the displayed VFO frequency) remains the same. It is useful if the other station is off-tune, or drifting; other uses include working DX stations who may be listening on a different frequency some kHz away from their transmit frequency.

This radio transceiver allows RIT values from -9,999Hz to +9,999Hz.

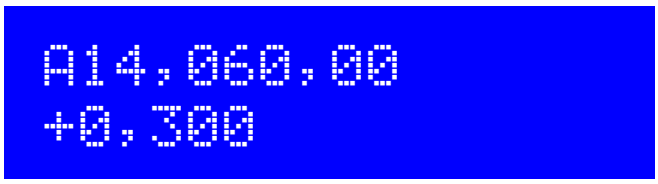
The default RIT at start-up is a configuration item in the VFO menu (see later). RIT can be easily adjusted during ordinary operation by double-clicking the left button:

Now use the rotary encoder to tune the RIT. As you do so, you will hear the RIT immediately applied to the VFO.

The tune rate of the RIT control is again indicated by the underlined digit (here 100Hz). In order to change the tune rate, press and hold the centre button (in the rotary encoder shaft) and turn the rotary encoder at the same time. You will see the cursor move to the left or right 1 digit at a time. Again, the cursor under the comma indicates 500Hz tuning steps.

To cancel RIT tuning (reset the RIT to zero), press the right button (exit); this returns to main operating mode and sets the RIT to zero.

To return to the main operating mode, press the left button (select). Now the RIT is displayed under the VFO, for example:



Remember that cancelling RIT mode is easy, just double-click the left button to show the RIT editing, then press the right button to cancel it (which means, set it to zero).

4.7 VFO mode

A single press on the right button changes the active VFO mode. There are two independent VFOs named A and B. There are three VFO modes for using these VFOs:

- VFO A is active as transmit and receive VFO; if non-zero, RIT is applied during receive
- VFO B is active as transmit and receive VFO; if non-zero, RIT is applied during receive
- Split: VFO A is used for receive, VFO B is used for transmit; RIT is ignored completely

Split mode is often used by DX stations, they transmit and receive on separate frequencies.

4.8 VFO A/B frequency swap

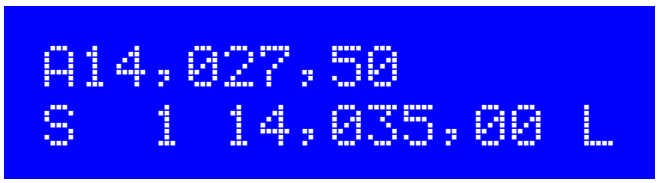
The contents (frequency) of VFO A and B can be swapped by a single long key-press to the right button. This can be useful when setting up the VFO frequencies.

4.9 Frequency Presets

There are 16 frequency presets which may be used for storing your favourite frequencies, or for just temporary use, or however you wish!

The presets are labelled 1 to 16, and can be individually edited in the Preset menu (see later). Often it is more convenient to just save them from the current VFO frequency.

To show the list of preset frequencies in normal operation mode, double click the right button. The display now shows something like this:



The top row of the display shows the currently active VFO frequency as usual.

The bottom row shows a “1” in the 4th character, this is the number of the preset displayed. The next number (here 14,035,00) is the frequency stored in Preset 1.

Use the rotary encoder to scroll through the list of presets until you find the one you want. Once you have selected the desired preset, press one of the three buttons to Save, Cancel or Load the preset, as follows:

- SAVE the current VFO to the selected preset, by pressing the left button
- CANCEL the preset operation (back to main operating mode), by pressing the centre button
- LOAD the selected preset frequency into the current VFO, by pressing the right button

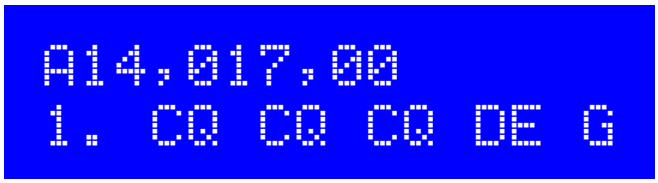
The “S” in the first character and “L” in the 16th character at the far right, are intended as a reminder of which button to press to Save and to Load.

4.10 Automated message transmission mode

My favourite use of the automated message transmission mode is to send a CQ call repeatedly. If a station answers, you can start transmitting and it cancels the automatic CQ mode.

There are 12 message memories. The first four memories are 100 characters long; the remaining eight memories are 50 characters long.

In order to send a pre-saved message, press the centre button with a single long press. The first of the saved messages is shown on the screen, for example if a CQ call is stored in Message 1, you may have something like this:



The bottom row shows the message number at the far left (here it is message 1) followed by the first part of the stored message. If it is blank, that means of course that you have not stored any messages yet!

You can now use the rotary encoder to scroll back and forth between the 12 stored messages and find the one which you want to transmit.

The message can be transmitted multiple times according to the “Repeats” parameter in the Messages menu (see later description). The interval between the repeated transmissions is also defined in the Messages menu, in the “Interval” parameter.

Once you have selected the message that you want to transmit, press one of the three buttons as follows:

- REPEAT: Transmit the message repeatedly by pressing the left button
- ONCE: Transmit the message only once by pressing the centre button
- CANCEL: Cancel the messages operation by pressing the right button

When REPEAT message transmission mode is activated, the number of repeats and the interval between repeats is as specified by the Repeats and Interval parameters in the Messages menu.

The stored message transmission is sent at the currently defined keyer speed.

During the actual stored message transmission, you can immediately cancel the transmission at any time by pressing the right button (exit) or by keying the transmitter with the onboard microswitch Morse key, or a paddle if you are using one.

4.11 Menu System

There is an extensive menu system with more than 80 different configuration or operating parameters stored in non-volatile memory (EEPROM). These are editable to control every aspect of the radio’s behaviour.

The menus are organised into 9 groups as follows:

- 1. Preset
- 2. Messages
- 3. VFO
- 4. Keyer
- 5. Decoder
- 6. Beacon
- 7. Other
- 8. Alignment
- 9. Test equipment
- Save settings!

To enter the menu system, give a single long press to the left (select) button. Use the rotary encoder to scroll back and forth between the nine sub menu groups listed. To enter one of them, press the left (Select) button. To return to the main operating mode, press the right (Exit) button.

The golden rule while in the menu system, is to press the left (Select) button to go in to a deeper menu level or edit an item, and the right (Exit) button to back up.

In order to edit a menu item, navigate to the menu item then press the left (Select) button to start editing. When you have finished editing the item, press the right (Exit) button to save it.

NOTE that changes to configuration parameters only take effect on the radio, when you leave the menu system and return to the main operating mode. During viewing or editing of menu items, the radio remains in receive mode on the currently selected VFO frequency. The exception to this is certain alignment and test equipment tools, where these need to use parts of the radio.

4.12 Saving current operating parameters (VFO frequency etc)

The final (10th) item “Save settings!” is a special item which causes certain operating parameters to be stored to EEPROM. These then are the defaults the next time you power up the radio. This is very convenient if you want to recommence operating next time you switch on, with exactly the configuration your radio is in now. The controls sequence to save the settings is very simple. This makes it easy and quick to save your current configuration when you wish to switch off the radio.

a) Single long press to the left button, to enter the configuration menu system
b) Turn the rotary encoder one click anticlockwise to show “Save settings!” on the screen
c) Press the left button once more, to actually save the settings

The list of items saved is:

- VFO Mode (A, B, Split)
- VFO A frequency
- VFO B frequency
- Tune rate
- RIT
- RIT tune rate
- Signal generator frequency

4.13 Types of configuration menu item

There are five types of menu configuration item, and editing these is a little different depending on the type.

1) LIST: a fixed list of values applicable to that menu item, for example Keyer mode
2) BOOLEAN: an ON/OFF parameter, such as used to control whether the battery icon shows
3) NUMBER: a numeric parameter such as a stored frequency preset
4) TEXT: a text configuration item such as a stored message
5) UNEDITABLE: some menu items are display-only, such as the alignment or test tools

4.14 Editing a configuration menu parameter

To start editing a parameter, navigate to the desired parameter in the appropriate menu, and then press the left button (Select). When editing is active, you will see a cursor appear under the digit being edited. For example, here is menu item 2.13, the message repeat interval:

The underline cursor below the 4 indicates that editing is active; turning the rotary encoder will change the parameter value.

When you are finished editing, press the right (exit) button to conclude editing. This saves the parameter in the microcontroller's EEPROM memory.

A flashing inverted cursor is also available, you can choose that in the "Cursor Style" parameter in the "Other" menu (see later section).

4.15 Editing a LIST parameter

Editing a list parameter is very simple, it is just a matter of turning the rotary encoder. The display scrolls through the list items. For example, this is the Keyer mode parameter, menu 4.1:

Note that the editing indicator cursor appears under the leftmost character.

When you are happy with your selection, press either the left or right buttons, to save the change.

4.16 Editing a BOOLEAN parameter

Editing a BOOLEAN parameter is exactly the same as editing a LIST parameter, except that now the list of items is always restricted to just ON and OFF (representing True/False).

4.17 Editing a NUMBER parameter

When editing a number parameter, the cursor underline appears under the currently edited digit. The cursor starts at the far left (most significant digit). The rotary encoder tunes the digit. The operation is very similar to tuning a VFO in ordinary operation. This example shows editing the default (power-up) VFO A frequency:

To alter the “tuning rate”, you can either

a) Press the left (select) button to move the cursor to the next digit to the right OR
b) Press and hold the centre button, while turning the rotary encoder shaft – this allows you to move the cursor left or right.

Editing of the number is concluded, and the number is stored to EEPROM, when either:

a) You press the right (exit) button OR
b) You press the left (select) button so many times that the cursor falls off the right hand side

Yet another way to input numbers, which is a REALLY convenient way, is to use the Morse key and CW decoder! During editing of numeric parameters, the CW decoder is activated but only decodes number characters 0-9. The CW decoder expects well-timed CW, with correct spacing between words and characters. The CW decoder expects you to key in the numbers at near to the configured Keyer speed. If you start keying at a much different speed, the CW decoder will adapt to your keying but this may take several characters to “sense” your keying speed, so some characters can be missed.

When you have keyed in the whole number, the number is automatically saved to EEPROM, which leaves editing mode. Once you are used to editing numeric parameters by keying in CW, it becomes the easiest and fastest way to edit menu parameters.

4.18 Editing a TEXT parameter

An example of a text parameter you may wish to edit is the stored messages. For example, stored message 2 is edited in menu item 2.2:

By far the easiest way to edit TEXT parameters is simply to use the CW decoder! As before, it expects well-timed CW, with correct spacing between words and characters. The CW decoder expects you to key in the characters at near to the configured Keyer speed. If you start keying at a much different speed, the CW decoder will adapt to your keying but this may take several characters to “sense” your keying speed, so some characters can be missed.

Editing of the parameter is concluded either when you press the right button (exit), or when no more characters are available for editing; for example, if you filled up the chosen Message memory.

It is also possible to edit a text parameter entirely with the buttons and rotary encoder, though this is usually a slower way to edit text parameters. Owners of the QRP Labs Ultimate3S (or earlier) QRSS/WSPR transmitter kits will already be familiar with this style of editing text.

The text parameter supports all of the characters which the Message keyer can encode, which is the same as the CW decoder can decode. Specifically, A to Z, 0 to 9, Space, then punctuation characters / \ ? . , (note, the break character \ appears at the moment as the Japanese yen character ¥ - this will be fixed in a future firmware version).

The following characters/symbols have special functions.

Insert: Use this symbol to insert a character in the text. Find this character using the rotary encoder, then press the left button to activate it. All the characters to the right of the cursor position are shifted right one position, including the character which was originally in the current position.

Backspace (delete): If you select this character as the current character using the rotary encoder, then when you press the left button, the current character is deleted and the cursor moves back left one position.

Delete all: If selected as the current character, pressing the left button has the effect of deleting the entire message, starting again at the left of the screen. There is no “undo”, so use with caution!

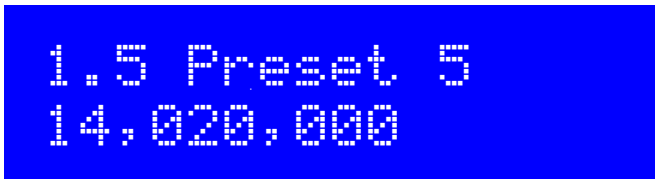
Enter Right (finished): The behaviour of this symbol is the same as Enter, except that it preserves all the text, including the text to the right of the cursor. It simply saves the whole line.

Enter (finished): If selected as the current character using the rotary encoder, pressing the left button is used to finish editing the setting. The setting is saved, and you leave editing mode. Note that the text that is saved is only the text to the left of the Enter symbol. If you select this symbol and press the left button when you are not at the furthest right position of the message, then everything right of your position is deleted.

You can also move the cursor backwards and forwards within the text being edited, by pressing and holding the centre button, then turning the rotary encoder. This moves the cursor position within the text parameter.

4.19 Frequency presets menu

There are 16 frequency presets, labelled 1 to 16. This example shows Preset 5:



All of the Preset menu items are NUMBER types. Refer to the “Editing a NUMBER parameter” section above for instructions on how to edit a NUMBER parameter.

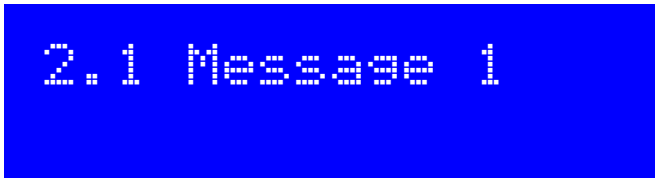
It is also convenient to load the current VFO into the preset memories as described in the section above titled “Frequency Presets”.

4.20 Messages menu

There are 14 configuration items in the Messages menu:

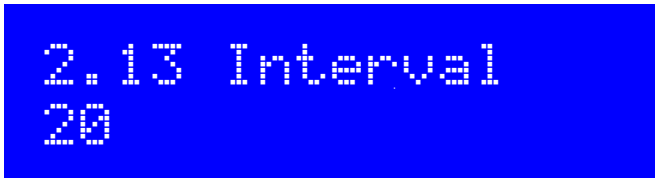
2.1 Message 1 (100 characters text stored message)
2.2 Message 2 (100 characters text stored message)
2.3 Message 3 (100 characters text stored message)
2.4 Message 4 (100 characters text stored message)
2.5 Message 5 (50 characters text stored message)
2.6 Message 6 (50 characters text stored message)
2.7 Message 7 (50 characters text stored message)
2.8 Message 8 (50 characters text stored message)
2.9 Message 9 (50 characters text stored message)
2.10 Message 10 (50 characters text stored message)
2.11 Message 11 (50 characters text stored message)
2.12 Message 12 (50 characters text stored message)
2.13 Interval
2.14 Repeats

The 2 stored message presets are 100 or 50 characters long, according to the list above. For example:

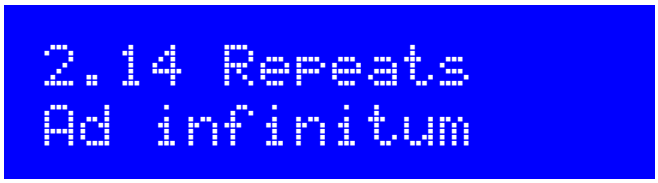


Turn the rotary encoder to select the Message from 1 to 12 which you wish to edit, then press the left (“select”) button. Now you can edit the message text in one of two ways:

1) Choose each character individually from the list, using the rotary encoder. When you have chosen the correct character, press the left (“select”) button to move to the next character. This process is described in more detail in the preceding section on editing text parameters.
2) Key in the desired text on the straight Morse key on the board, or using your external paddle. The CW decoder must be enabled for menu editing (see “Enable edit” parameter).



The Interval is a NUMBER parameter that specifies the interval in seconds, between repeated transmission of a stored message (if repeats are configured: see next parameter).

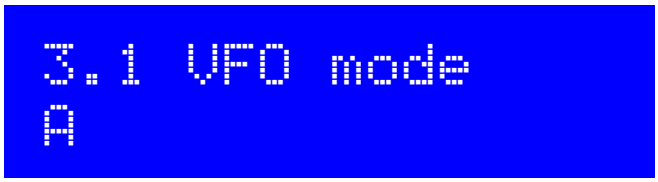


The Repeats parameter specifies how many times the message transmission will be repeated, in the repeat transmission mode. The Repeat parameter is actually a LIST type, since it can be a number from 1 to 99, or “Ad infinitum”. In the latter case, the Message transmission continues indefinitely (ad infinitum).

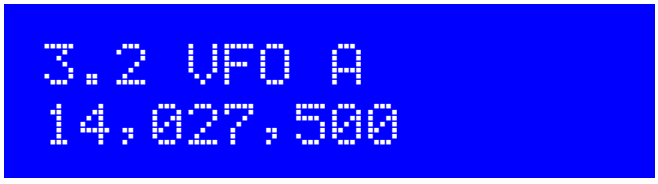
4.21 VFO menu

The VFO menu contains a number of configuration parameters which affect the VFO operation and CW reception. Many of these parameters are only power-up default parameters for the VFOs. The current VFO frequency, mode etc is not stored in these parameters. If you wish to save the current VFO frequency, mode etc into EEPROM so that when the radio is next powered up, the exact same state is available from power up, use the “Save settings!” feature described previously.

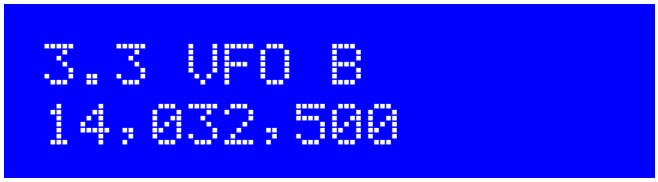
These configuration items in this menu are explained below.



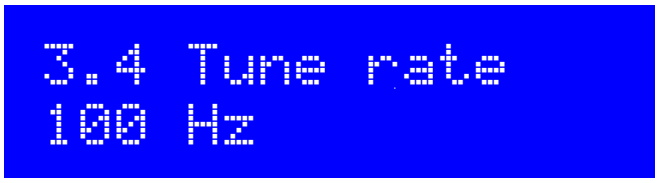
This parameter specifies the VFO mode at power-up. It can be A, B or Split. The current VFO mode during ordinary operation is not stored in this parameter unless you “Save settings” as described previously.



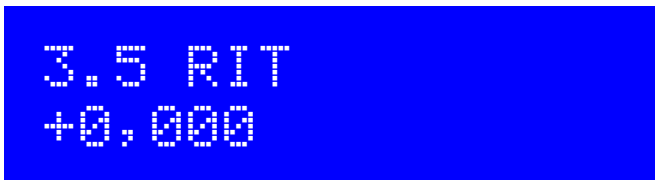
This parameter specifies the VFO A frequency at power-up. The current VFO A frequency during ordinary operation is not stored in this parameter unless you “Save settings” as described previously.



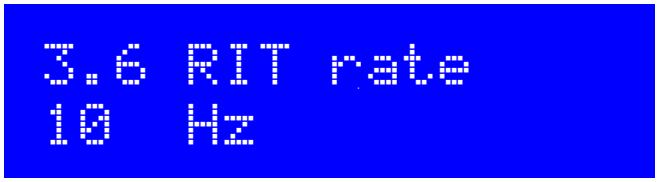
This parameter specifies the VFO B frequency at power-up. The current VFO B frequency during ordinary operation is not stored in this parameter unless you “Save settings” as described previously.



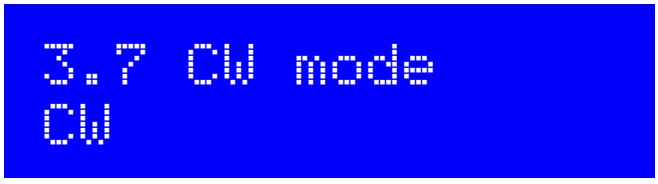
This LIST parameter specifies the Tune rate power-up. Available values are: 10MHz, 1MHz, 100kHz, 10kHz, 1kHz, 500Hz, 100Hz, 10Hz or 1Hz. The current Tune rate during ordinary operation is not stored in this parameter unless you “Save settings” as described previously.



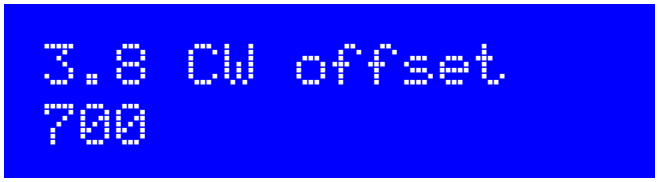
This parameter specifies the RIT at power-up. The current RIT amount during ordinary operation is not stored in this parameter unless you “Save settings” as described previously.



This parameter specifies the RIT tuning rate at power-up. The current RIT tuning rate during ordinary operation is not stored in this parameter unless you “Save settings” as described previously.



This LIST parameter specifies the CW mode. Ordinarily CW is received in Upper sideband with a 700Hz offset. They may be some occasions where operation on the other sideband is desired (lower sideband), for example to exclude an interfering nearby station when the CW filter performance is asymmetric. In these cases you can change the parameter value to CW-R (reverse mode CW) to select Lower sideband reception mode.



This parameter specifies the CW offset in Hz. It is the difference between the VFO frequency during transmit and receive. It is automatically applied during receive in order to resolve a perfectly netted transmission on the same frequency as yours, at 700Hz audio output.

If you wish to change the CW offset frequency you may do so using this parameter. However, be warned that the 200Hz audio analogue filter in the circuit is still centred on (approximately) 700Hz. If you moved the configured CW offset frequency too far away, then the received audio will fall outside the CW filter and be attenuated.

The chosen band configuration for your radio. On first powering up the radio, the display requests your selection of band, and it is stored in this configuration parameter. You are not likely to need to touch this setting again. Changing the band results setting sets a frequency in the chosen band, 20kHz above the lower band edge. This frequency is written into:

- VFO A
- VFO B
- Presets 1 to 16
- Alignment frequency
- Beacon frequency

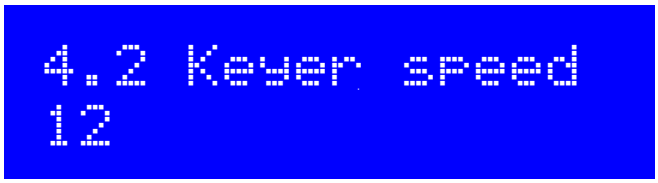
4.22 Keyer menu

The Keyer menu contains a number of configuration parameters relating to the CW keyer, which are described below.

The mode of the CW keyer function in the firmware. Possible modes are:

- Straight
- IAMBIC A
- IAMBIC B
- Ultimatic

If you wish to use a traditional up/down Morse key, or the onboard microswitch, these are called “straight” keys and you should select the “Straight” mode. If you wish to use a modern paddle plugged into the 3.5mm socket on the right side of the transceiver PCB, then select the desired operating mode e.g. IAMBIC A.

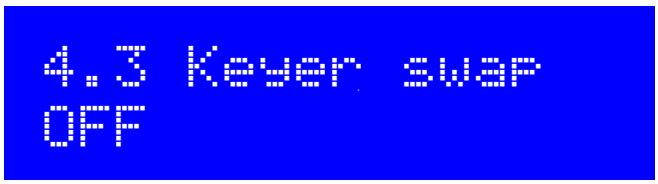


This is the default power-up speed of the Keyer function in Words Per Minute (wpm). The current Speed during ordinary operation is not stored in this parameter unless you “Save settings” as described previously.

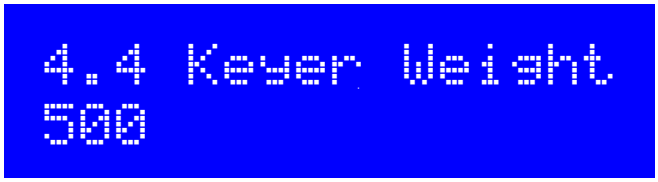
Keyer speed can be altered easily from the ordinary main operating mode, with a single press of the left button, as described previously.

Keyer speed is also used for stored message sending, and for the beacon function when in CW mode.

The keyer speed is also used to configure the CW decoder during transmit or during menu item editing. When transmit or editing are commenced, the speed is copied into the CW decoder and initialises it. Thereafter if you transmit (or enter data during editing) at a different speed, the CW decoder will adapt to your speed. However, if the speed difference is large, the adaption can take several characters to correctly “sense” your keying speed, which can result in incorrectly decoded characters or missed characters.



This is a BOOLEAN parameter which lets you swap the “dit” and “dah” connections in software, if you find that your paddle is reversed.



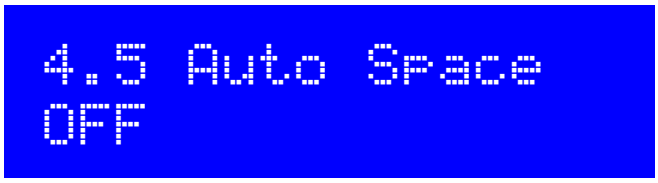
Ordinarily Morse dit and dah durations have a 1:3 ratio. The space between symbols is equivalent to 1 dit, between characters 3 dit lengths, and between words 7 dit lengths. This is standard Morse timing. However, some people may wish to alter this, for various reasons.

The Keyer Weight parameter allows variation of the ratios. The value has three digits. The default value of 500 corresponds to 50.0%. This means the “duty cycle” of a stream of dits is exactly 50%. The key-down dit length is therefore the same as the key-up inter-symbol pause.

If the weight is increased from the default 50.0%, then the key-down “dit” is made longer. A “dah” is lengthened by the SAME amount. The corresponding inter-symbol (or character, or word) gap is shortened by the same amount. The additional time spent on the key-down is therefore taken from the key-up period. The keyer speed is unchanged by altering the weight parameter.

As an example: suppose you want to make your Morse sound “harder” by shortening the dits and dahs. You could set the parameter to 450, which means 45.0%.

The parameter range is 050 to 950 (5% to 95%) though you would not normally ever need to go anywhere near these unreasonable limits. In the event that you enter a value outside this range, the firmware automatically applies these limits to the actually used parameter.



Auto-spacing means that the pause between CW characters is forced to be 3 dit lengths (more or less, if you have CW weighting configured, see above).

The majority of keyers do not implement auto-spacing. You use the paddle to send your dits and dahs making up the Morse character you wish to send. As soon as you next press the paddle, the next character is started. The keyer forces correct 1:3 ratio of dits and dahs and inter-symbol spacing, but it does not force you to wait for the correct duration of 3 dits between transmitted characters.

Some keyers do implement automatic character spacing, such as the old (1973) Accu-Keyer design by James WB4VVF see https://inza.files.wordpress.com/2011/01/accu-keyer.pdf .

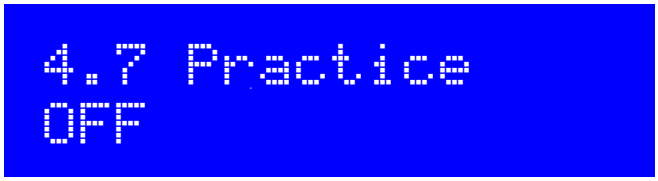
This configuration therefore allows you to switch on automatic character spacing if you wish. In this case, if you press a paddle too SOON, before the 3 dit durations have elapsed after the last character completed, the keyer will wait until the correct time to start the next character.

In the even that you press the paddle too LATE, there is nothing the keyer can do to travel back in time and force it to 3 dit lengths for you. You might have intended an inter-word space, for example. So pressing the paddle too late cannot be corrected.

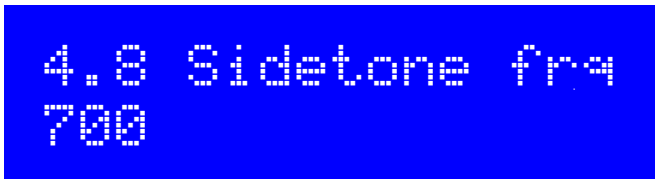
This setting defines the break-in (QSK) behaviour of the radio. Two settings are possible:

Full: after the delay time for RF envelope shaping, the Transmit/Receive switch is set to “Receive” shortly after key-up. In this way, you will hear the other station (or any QRM, QRN etc) transmitting in between the dits and dahs of your own transmissions. Many experienced operators like to be able to have a feel for what is happening on the band, in between their key-downs. In some ways you feel like you are listening to your own sidetone audio as just another signal on the band, and you can still hear other signals too.

Semi: After key-up, there is a delay before the Transmit/Receive switch is set back to “Receive” mode. The receiver is therefore kept muted during your whole CW transmission, not listening to the band in between your transmitted symbols. Many operators prefer to avoid the distraction of hearing the band between their dits and dahs. In Semi-QSK mode the Transmit/Receive switch is set back to “Receive” only after a suitable delay (of 8 dit lengths), long enough to occur only at the end of the transmission.

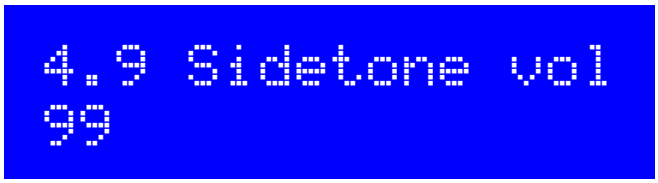


Normally you would leave Practice mode switched OFF. However if you want to practice sending CW, and see if the CW Decoder can decode you, then you can switch Practice mode to ON. In practice mode, the radio does everything it normally would, except that it never sends any RF power to the antenna!



This NUMBER parameter allows you to change the Sidetone frequency if you wish. Sidetone is the audio tone which is generated by the microcontroller on key-down and injected into the audio signal path. Sidetone is ONLY an operator convenience to let you hear your keyed signal, and has no impact at all on the transmitted RF amplitude or frequency.

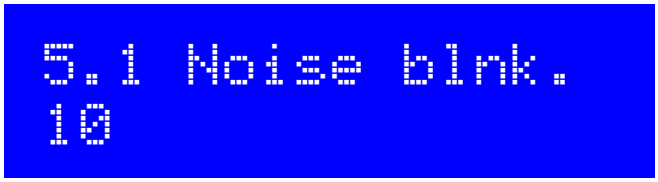
It is strongly recommended to leave the Sidetone frequency set to the same frequency as the CW Offset frequency in the VFO menu. Your ears will get used to recognising the 700Hz audio tone, and it makes it then much easier to accurately tune to a station you hear transmitting on air, such that his signal will also be at 700Hz audio in your receiver. When you hear him at 700Hz, he will be in the middle (near, anyway) of your CW audio filter. When you transmit you will also be netted accurately to his frequency. All being well, this should mean that your signal also ends up nicely in his CW filter passband too. Then you can QSO!



You can use this parameter to reduce the volume of the sidetone audio. Most people will find the default setting of 99 too loud. So experiment with lower values until you find a sidetone audio level which you find comfortable.

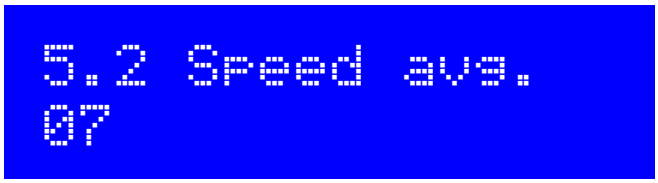
4.23 Decoder menu

The Decoder menu contains a number of configuration parameters relating to the CW decoder, which are described below. Some of these parameters control some aspects of the decoder behaviour. Some constructors may find it interesting to experiment with these settings and see if you can improve the performance of the CW decoder in your specific circumstances. For example, some stations may experience more noise interference than others, depending on your location etc.



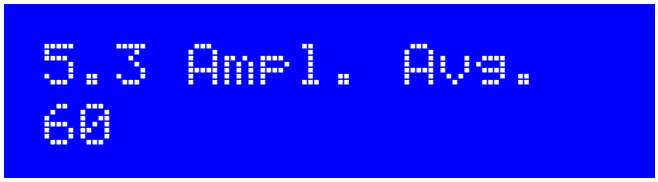
This parameter defines the duration of the noise blanker in milliseconds. The microcontroller's 10-bit ADC samples audio at 12.019 samples per second. 48 samples are analysed by an implementation of the Goertzel algorithm (kind of a single bucket of a Fourier Transform), which results in a digital filter bandwidth of 250Hz. In other words, it results in a measurement of the amplitude 250 times per second, i.e. once every 4 milliseconds. The amplitude is analysed by logic which compares it to a threshold amplitude to decide if a tone has been detected or not. Impulse noise that generates shorter pulses than the noise blanker parameter, is ignored.

If the noise blanking period is too short, then noise impulses will not be blanked effectively. On the other hand, if the noise blanking period is too long, then it will impair the decoder's ability to decode high speed Morse. For example, 24wpm Morse has dits lasting 50 milliseconds.



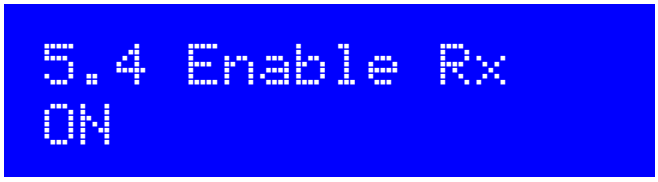
The duration of dits and dahs is measured in order to define a threshold at which to define a tone burst as a dit or a dah, and whether to define no tone at all as an inter-symbol, inter-character or inter-word gap. The measurement of this timing is implemented via an exponential moving average, whose averaging duration is determined by this parameter (the weight of each new measured symbol in the accumulated average).

If the exponential moving average is too fast (the parameter value is too low) then noise etc will throw off the timing averages too easily. If the exponential moving average is too slow (the parameter value is too high), then too many characters of the other station's transmission will be missed, while we try to adjust to the speed of his sending. This can be particularly offensive in some contest or pileup situations where exchanges are very short.

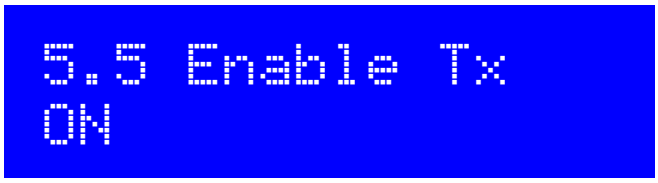


The decoder maintains an amplitude threshold, which it uses to decide whether a tone is detected or not. The level of this threshold must be varied automatically in order to cope with stations having a wide range of different signal strengths. Other perils may include QSB (signal fading) of the station you are listening to. The amplitude threshold is implemented via an exponential moving average. The weighting of each new sample (every 4ms) added to the accumulated exponential moving average value is the reciprocal of this parameter.

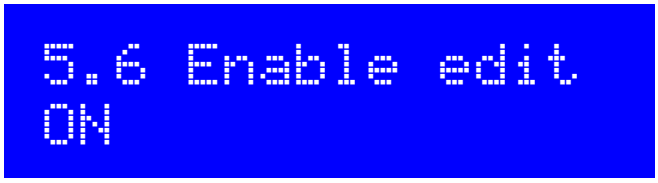
If the exponential moving average is too fast (the parameter value is too low) then noise etc will too easily throw off the amplitude threshold and it may take time to recover to its proper level. If the exponential moving average is too slow (the parameter value is too high), then it may take too long to adjust to the received station's amplitude, resulting in missed characters while the decoder slowly adjusts itself. It would also be too slow to automatically respond to QSB (signal fading).



An experienced CW operator may well dislike the CW decoder scrolling across the display all the time. With this setting you can switch "Enable RX decode" to OFF and the receiver decoding is disabled.



With this setting you can switch "Enable TX decode" to OFF and the transmit decoding is disabled. When this setting is ON, the CW decoder will decode your own keying and display it on the screen while you transmit. For an experienced CW operator that may be distracting too!



This parameter enables CW decoding while editing. When ON, anything you key during editing of NUMBER or TEXT type configuration parameters, edits the parameter. This is a really useful feature that makes it very easy to enter frequencies or stored messages, for example.

4.24 Beacon menu

The beacon function is an added bonus feature of this QRP Labs CW transceiver kit! We already have extensive experience for several years, developing the Ultimate-series QRSS/WSPR transmitter kits (current incarnation, the Utimate3S). These have a huge array of functionality and modes including CW, QRSS, DFCW, FSKCW, Hellscreiber (full speed and slow FSK), WSPR, JT9, JT65, ISCAT, Opera and PI4. The vast majority of people use the Ultimate3S kit for WSPR operation. Since it costs nothing (no extra hardware, at least) to add this functionality to the CW transceiver, why not! Let's do it!

The CW transceiver beacon function therefore contains a simplified WSPR implementation which can transmit standard WSPR messages. It also has a GPS interface for discipline of time, frequency and Maidenhead locator. The implementation of course does not have the full range of flexibility and functionality as the Ultimate3S kit.

WARNING: WSPR transmissions operate a continuous 100% key-down duty-cycle for almost 2 minutes. You should check carefully whether the BS170's get too hot during this period. WSPR is much more demanding on the PA transistors than CW. If you are operating with higher output powers (by using a relatively high power supply voltage) then you might notice the BS170s get unreasonably hot. Even though the output stage is Class-E, nothing is 100% efficient! It will still dissipate some power as heat. In this case you may need to fix the BS170 transistors to a small heatsink to help dissipate the heat. The BS170 transistors Q1, Q2 and Q3 are placed at the edge of the PCB with their flat sides facing outwards, to facilitate this

The beacon function can also operate a CW beacon.

Weak Signal Propagation Reporter

WSPR stands for Weak Signal Propagation Reporter. It is digital message format filled with clever forward error correction. The message consists of three parts: the operator's callsign, Maidenhead locator (4-character, e.g. IO90) and two digits specifying the power. At the receiving station, messages are decoded and uploaded to a central internet database. At any time you can go to WSPRnet http://wsprnet.org and click on the map, enter your callsign (and other filters if you wish), and see a map of where your signal is being heard.

You could also undertake more in-depth propagation studies by downloading the database of reception reports.

The WSPR message is encoded into a set of 162 symbols, each may be 0, 1, 2 or 3, using a compressed data format with forward error correction. The symbols are transmitted as tones, each tone separated by 12,000 / 8,192 Hz i.e. approximately 1.46Hz. The duration of each symbol is the reciprocal of the tone spacing, which is approximately 0.683 seconds. WSPR messages take about 110.6 seconds to transmit, and always start at even minutes past the hour.

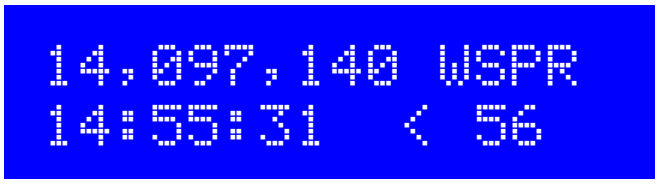
Due to the very narrow 6Hz bandwidth of the transmission, and the clever forward error correction, WSPR signals can propagate globally even with a fraction of a watt.

In WSPR, timing is critical, so when using WSPR you must set the time configuration parameter as exactly as possible. Be sure to keep the editing cursor under the rightmost (1-minute) digit of the time parameter, watch your clock until the seconds turn over to 00, and then press the left button. This will ensure the seconds are in sync with your real clock time. If careful attention is given to setting the frequency and the real time clock, then successful WSPR reports will be obtained. Of course these things are easier if you are using a GPS module: the Maidenhead

locator will be calculated from the received latitude and longitude, and the time decoded nicely from the GPS serial data stream.

The microcontroller in this kit takes care of the WSPR message encoding algorithm, without any assistance from a PC host computer. It also calculates the tone spacing and symbol duration.

In between message transmissions, the display will show instead just a clock (see below), while we wait patiently for the next WSPR transmission to begin, according to the settings of the configuration parameters Frame and Start. This is useful for checking that the time on your kit is accurately set. The display also shows the minute at which the next frame will start transmitting. In the example below, the time is 14:55:31 UT and the next frame will start at 14:56:01.

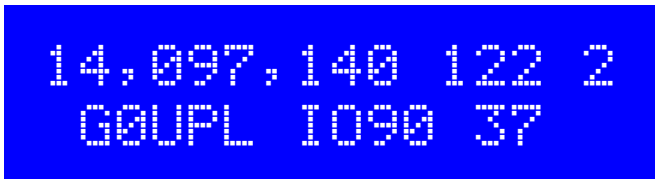


When a GPS unit is connected, the firmware automatically uses the 1 pulse-per-second signal to measure the transmit frequency and compensate for any inaccuracy due to calibration error or frequency drift due to temperature. The serial data stream from the GPS is used to set the real time clock (for syncing the WSPR transmission timing). The Maidenhead locator is computed from the latitude and longitude information parsed from the GPS serial data.

A WSPR transmission takes 1 minute and 52 seconds. The GPS time and location data is parsed from the GPS serial data stream at the END of every WSPR transmission. On the first WSPR transmission after power up, the time may not be accurate. The 27MHz synthesiser reference frequency is measured and adjusted, in a 4 second period after the end of the WSPR transmission. Parsing the time and location, and adjusting the 27MHz reference frequency, all takes place in under 7 seconds. The process is completed before the start of the next WSPR transmission slot. Nevertheless, you should not configure your kit for continuous WSPR transmissions in every 2-minute WSPR slot (Frame parameter is 2), which is considered very antisocial to fellow WSPR operators.

A GPS receiver isn't essential for WSPR operation but it is highly recommended because it makes operation more accurate, easy and fun.

During the actual WSPR message transmission, the display shows something like this:

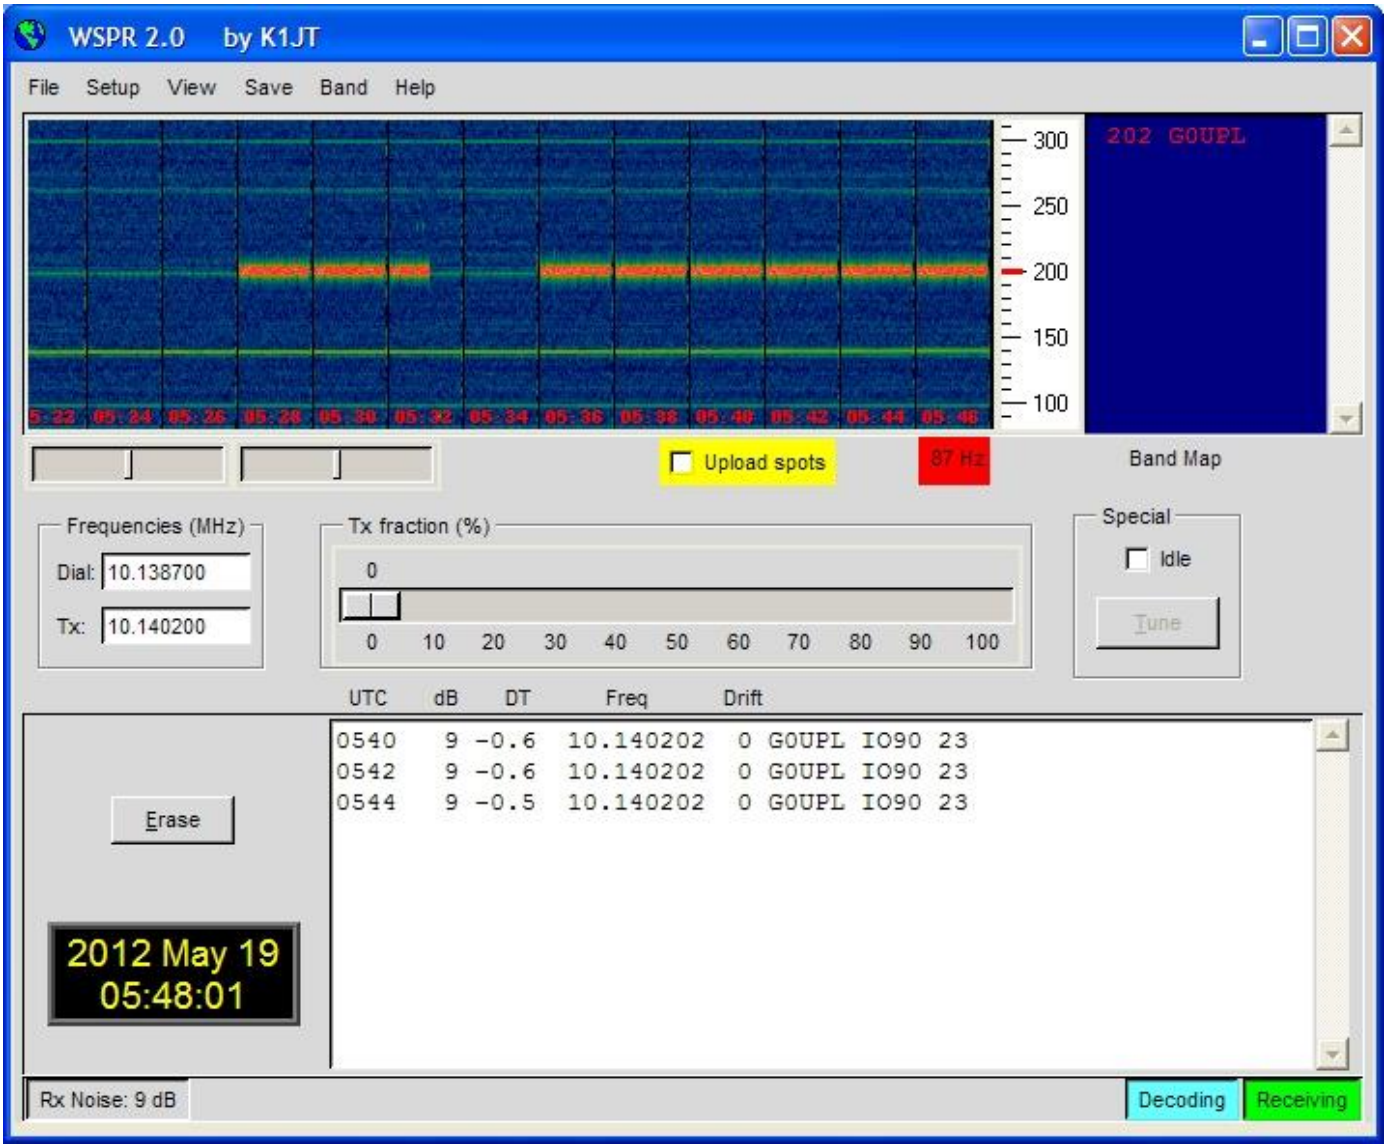


The elements of this display are explained as follows:

- 14,097,140 Transmission frequency (tone 0)
- 122 Current symbol is 122 (of 162 symbols making up a WSPR transmission)
- 2 Current tone being transmitted (one of 0, 1, 2 or 3)
- G0UPL Callsign encoded into the transmission
- IO90 5-character Maidenhead Locator square, encoded into the transmission
- 37 Power in dBm, encoded into the transmission

On a PC spectrum display such as the Argo software http://www.weaksignals.com/ WSPR messages look something like the screenshot below when received locally (or usually worse, because you probably are over-driving your receiver when receiving your own signal!):

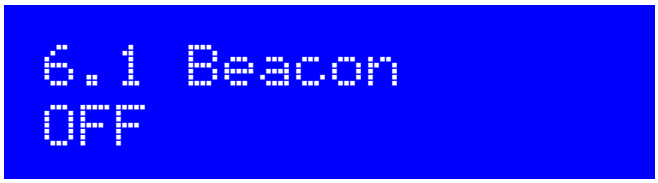
WSPR decoding takes place in the WSPR program by K1JT (see http://physics.princeton.edu/pulsar/K1JT/wspr.html). Below is a screenshot showing the WSPR 2.0 screen following reception of a few transmissions (output frequency = 1,500Hz, Frame = 02, Start = 00).



A number of other software packages are now also capable of decoding WSPR transmissions.

NOTE: the GPS interface is connected in parallel in the circuit, with the paddle. Therefore, you should NOT have the GPS connected, while operating the radio as an ordinary CW transceiver. If you do, the GPS serial data and 1pps will key the transmitter! Disconnect the GPS before using the radio as a CW transceiver.

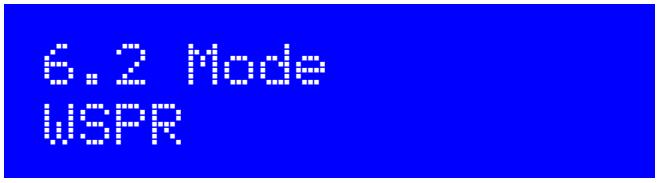
The following sections describe the configuration parameters in the Beacon menu.



This is the master switch controlling whether beacon mode is enabled or not. If beacon mode is enabled, then the radio starts operating in beacon mode on power-up.

While beacon mode is operational, it can be cancelled immediately at any time by pressing the right (exit) button. Remember that you should not have a GPS connected, when in ordinary CW transceiver mode – it would key the transmitter since the GPS and paddle share the same processor I/O signals.

Beacon mode is entered upon leaving the configuration menu system, if the beacon is enabled by having this parameter set to ON.



This parameter determines the transmission mode during beacon operation. There are two possible beacon modes:

CW: the kit simply sends stored message 1 repeatedly, according to the configured Keyer speed, and with message start timing determined by the Frame and Start parameters (see next sections).

WSPR: the kit sends WSPR according to the configuration parameters in the following sections.

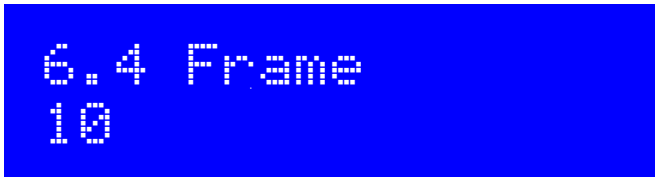
This parameter determines the transmission frequency during beacon operation. In WSPR mode, this is the frequency of tone 0.

It should be noted that the WSPR sub-bands on the bands are only 200Hz wide. You need to have your 27MHz reference oscillator accurately calibrated so that you can be sure your actual transmission frequency is close to the frequency specified in this parameter. You also need to specify the correct frequency so that your transmission is inside the appropriate 200Hz sub-band.

Note that these are the actual transmission frequencies, there is no CW offset, no RIT, no other modifications. The specified frequency is also DIFFERENT from the “USB dial frequency” specified at WSPRnet http://wsprnet.org – the “USB dial frequency” is 1500Hz lower than the actual transmit frequency, so that the decoded audio is at 1500Hz.

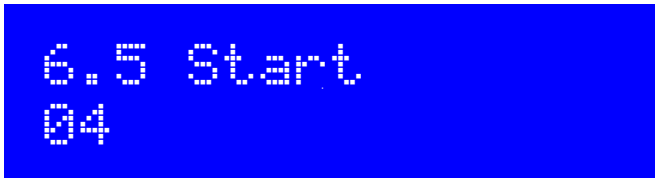
Therefore, ensure that for WPSR transmissions, you choose a frequency in one of the WSPR sub-bands according to the following table:

80m:	3.594000 – 3.594200
60m:	5.288600 – 5.288800
40m:	7.040000 – 7.040200
30m:	10.140100 – 10.140300
20m:	14.097000 – 14.097200
17m:	18.106000 – 18.106200
15m:	21.096000 – 21.096200
12m:	24.926000 – 24.926200
10m:	28.126000 – 28.126200



This parameter defines the repetition rate of the WSPR transmission. In the example shown here, Frame 10, this means that the WSPR message will be transmitted once every 10 minutes.

Transmission in every 2 minute WSPR slot is considered anti-social. 10 minute repeat transmissions is usually considered normal.



If everybody transmits with 10 minute repetition rate starting on the hour, then there will be bursts of activity every 10 minutes where everyone is transmitting at once, and the potential for interference from another station will be large. To avoid this, you can define the start timer. In this example a start time of 04 means that the first transmission will start at 4 minutes past the hour, and subsequent transmissions will commence at Frame minutes after that – in this case, 14, 24, 34 etc minutes past the hour.

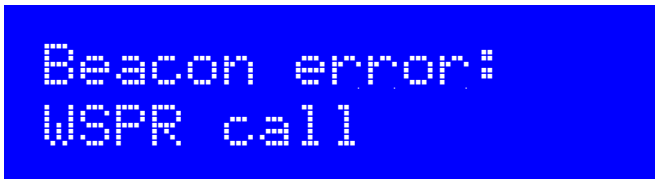
The WSPR callsign is the first parameter which is encoded into the WSPR message. Your callsign must obey certain restrictions imposed by the WSPR protocol. These restrictions helps ensure that the WSPR encoding process can compress callsigns efficiently, along with the Maidenhead Locator square and Power level, into only 50 binary bits of information in total.

The callsign can only be 4 to 6 characters long. The callsign must consist of the following:

1) One character which can be A-Z or 0-9 or a SPACE
2) One character which can be A-Z or 0-9
3) One character which must be a number 0-9
4) Three characters which can be A-Z or a SPACE

For callsigns such as mine, consisting of 5 characters, I must enter a space character as the first character in order to satisfy these callsign rules.

If the callsign you enter does not obey the necessary rules, then an error message is displayed on exiting the configuration menu system:

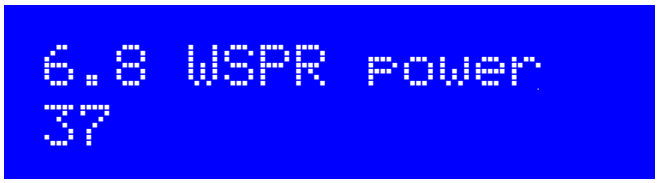


In this case, go back to the WSPR Call parameter and try to understand how to correct it in order to make your callsign satisfy the requirements.

Note that if entering the callsign text using the key, you cannot enter a space with the key! So, you will need to enter the initial space character (if required) using the buttons and rotary encoder as discussed in the earlier section on editing TEXT parameters.

The Locator is the second parameter which is encoded into the WSPR message. It is the 4-character Maidenhead square. The text you enter here, must be a valid Maidenhead square, otherwise an error message will be generated on exiting the configuration menu system.

If you have connected a GPS receiver, the GPS receiver can update the Locator, computing it from the latitude and longitude information contained in the serial data string from the GPS receiver module.



The third and final parameter encoded into the WSPR message is the transmitter power, defined in dBm. Note that this parameter is manually edited here and is encoded into the WSPR message. It does NOT indicate a measured power which is actually transmitted. This is a common misconception. It only indicates what number the operator configured for the WSPR message encoding.

WSPR powers are constrained to certain values 0, 3, 7, 10, 13, 17, 20, 23, 27, 30, 33, 37, 40, 43, 47, 50, 53, 57 and 60dBm. If you specify a value not in this list, then an error message will be generated on exiting the configuration menu system.

In this example, the configured value is 37dBm which corresponds to 5 watts of RF transmitter output.

The kit has an internal real time clock which is used for timing the beacon (WSPR and CW) transmissions. This configuration allows you to set the real time clock. The clock setting takes effect, and the seconds (internally counted but not displayed) are set to zero, when editing of this menu is concluded: either by pressing the left button after setting the minutes, or by pressing the right button at any time.

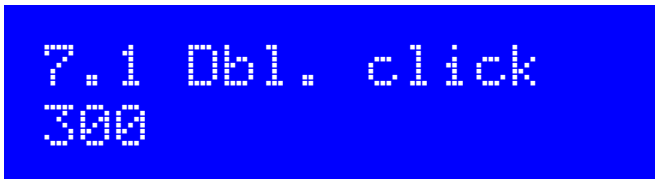
Accurate timing is critical for the WSPR (etc) modes. With careful adjustment of the “System frq.” parameter, the 20MHz oscillator will keep accurate enough time for WSPR for up to a week, even without GPS.

Note that if using a GPS module and if there is a valid serial data stream properly decoded, then the time is set automatically.

An accurate real time clock is not required other than for the WSPR beacon transmission timing.

4.25 Other menu

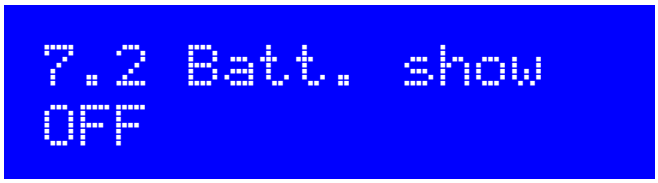
This menu contains miscellaneous other settings which do not fit well in other configuration menu categories.



This is a NUMBER parameter which controls the decisions on what type of press has been made to a button. By default, it is set to 300 milliseconds (as shown here) but you may alter this if you wish.

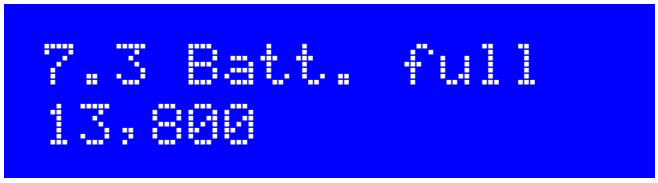
It is the number of milliseconds after first pressing the button, at which certain decisions are made:

a) If you have not pressed the button again after this interval, then it means you intended a single press.
b) If you are STILL pressing the button all this time later, 300 milliseconds after the first press, then it means you executed a “single long press”.
c) If you pressed the button again before the 300 milliseconds elapsed, it is a “double click”.

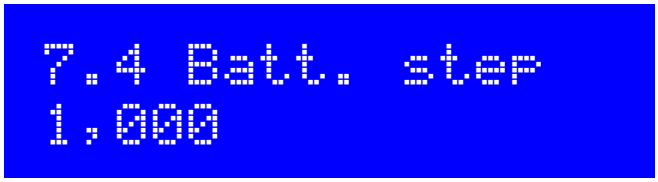


This BOOLEAN parameter controls whether or not the battery icon is displayed on the screen at the top right corner. Measurement and display of battery voltage may be useful to those operators who intend to operate the radio from battery power, for example during portable operations.

In order to measure and display the battery voltage, it is necessary to jumper the “DVM” input header pin to the supply voltage header pin. This hardware wiring is described elsewhere in this document.



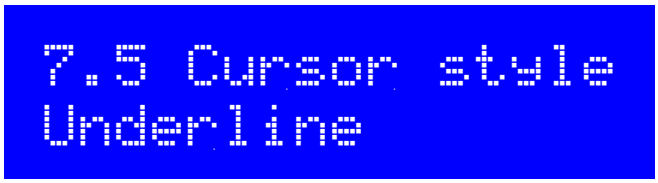
This is the voltage, specified in millivolts, at which the battery is considered “full”.



This is the step, specified in millivolts, for each bar of the battery icon.

In this example, Batt. full is defined as 13.8V and the step is 1V. The battery icon has 7 possible states, ranging from empty to full and 5 intermediate states in between. The meaning of the displayed icon will be, in this example:

- Full: 12.81V to 13.8V (and indeed, above 13.8V also)
- 5 bars: 11.81V to 12.8V
- 4 bars: 10.81V to 11.8V
- 3 bars: 9.81V to 10.8V
- 2 bars: 8.81V to 9.8V
- 1 bar: 7.81V to 8.8V
- Empty: 7.8V and below

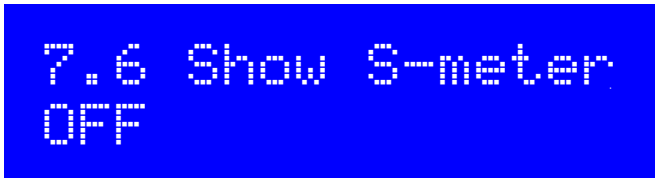


Two different cursor styles are possible. You can select your favourite, here. The two possible values are:

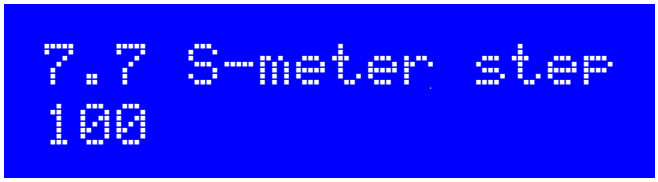
Underline: a simple solid line under the character being edited

Blink: the display alternates between the edited character, and a solid white block

Note that this setting only affects the cursor that is shown during menu system editing. In normal operating mode, the underline cursor is always used for tuning rate indication, regardless of the Cursor style setting.



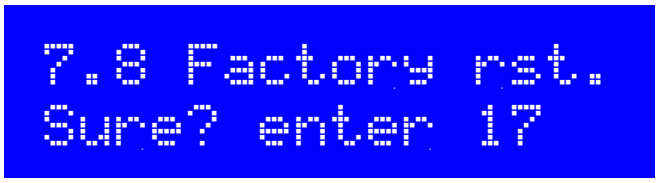
A rudimentary S-meter is shown in the top right of the display, if this parameter is set to ON.



This NUMBER parameter effectively defines the sensitivity of the S-meter. The S meter has 12 bars maximum. Each bar of the S-meter equates to the specified “S-meter step” number on the amplitude measurement scale. So, in this case the scale of the 12 bars of the S-meter will mean 0 to 1200 in amplitude measurement terms.

A lower S-meter step number makes the S-meter more sensitive; a higher number makes it LESS sensitive.

The S-meter reading is indicative only, it does not have any highly accurate meaning. In any case the audio sampled by the Analogue to Digital converter is after the audio amplifier gain stages so the amplitude depends on the receiver gain setting.



This menu item can be used to cause a factory reset. Factory reset returns you radio to the supplied default factory configuration. Everything is erased and set back to the default parameter values.

In order to prevent accidentally triggering this drastic step, the factory reset is implemented as a virtual 2-digit numeric parameter. To cause a reset:

- Press the left (“select”) button to start editing this menu item. 00 is displayed
- Use the rotary encoder to change the value to 17
- Press the left (“select”) or right (“back”) buttons to enter the value 17, which causes the factory reset

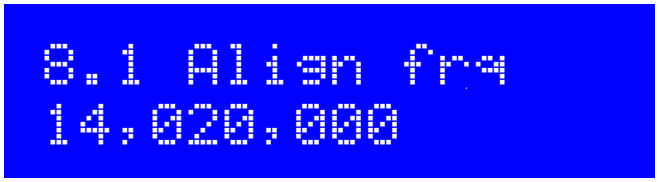
Factory reset takes a few seconds while the entire EEPROM contents are written. After the factory reset you will see the “Select band” prompt again, the same as when you first power up the radio.

4.26 Alignment menu

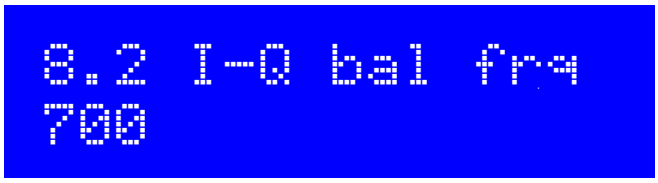
The alignment menu contains several tools for alignment and calibration of the radio, using the built-in signal generator to inject a test signal back into the receiver’s front end.

Correct use of these alignment tools makes it possible to adjust and align the receiver without any external test equipment at all.

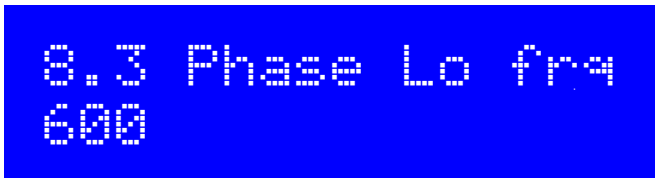
Please also refer to the alignment/adjustment section at the end of the assembly part of the manual, which describes how to use these tools to peak the Band Pass Filter response, and to minimise the unwanted sideband using the I-Q balance and audio phase shift adjustments.



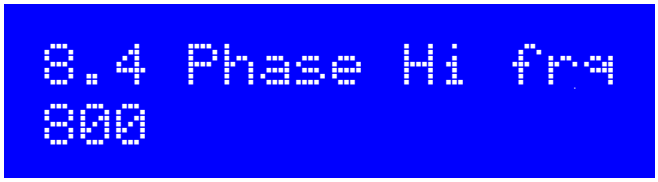
The Align frq. parameter specifies the frequency which the alignment tools operate. You should ensure that the frequency specified is in the centre of the CW section of the band of operation of your radio.



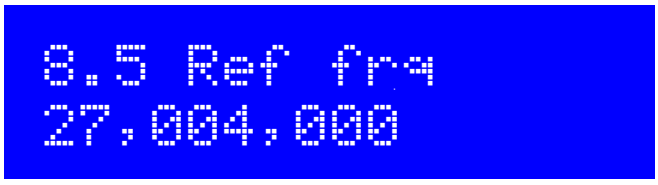
The audio frequency at which the I-Q balance adjustment is performed. By default this is set to 700Hz, the centre of the audio filter and what is usually used for the CW offset frequency.



The audio frequency at which the LOW audio frequency 90-degree phase shift is performed.



The audio frequency at which the HIGH audio frequency 90-degree phase shift is performed.

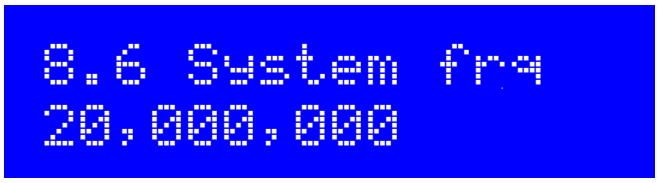


The reference frequency for the Si5351A synthesiser chip. If you set this to the actual oscillation frequency of the 27MHz crystal, then the output frequency of the radio will be accurate.

Usually the 27MHz crystals oscillate between 3 to 5kHz too high. This is the reason for the default setting of 27.004MHz (4kHz high).

You can measure the 27MHz reference value yourself if you have a reliable general coverage receiver whose frequency is known to be accurate. There are other methods too! You could set the signal generator to a certain frequency such as 10MHz. Then beat it against a 10MHz reference, for example. Measurement of the audio offset would enable a calculation of what the correct 27MHz reference value ought to be.

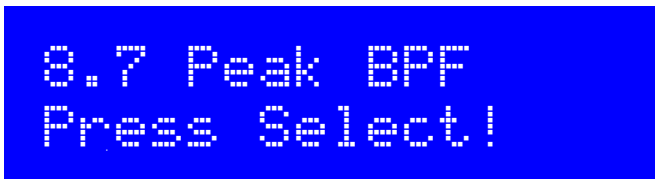
If a GPS unit is available, then this makes everything very simple – then you can use the GPS calibration tools to calibrate this value (see below).



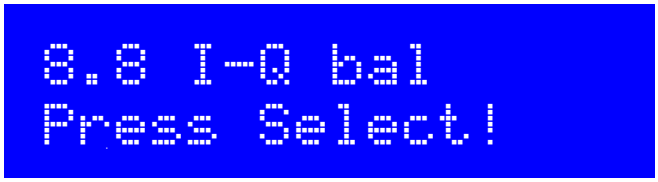
The system oscillator frequency. In this radio, the microcontroller clock is a 20MHz crystal. If you are able to measure the actual 20MHz frequency (without disturbing it), you can enter the frequency here. You could, for example, listen for the 20MHz radiation on a general coverage receiver whose frequency indication you trust.

The 20MHz system clock is used for timing purposes only. It is not very critical, unless you intend to operate the WSPR beacon function without a GPS.

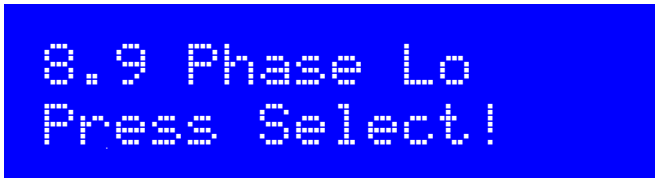
If a GPS unit is available, then you can use the GPS calibration tools to calibrate this value (see below).



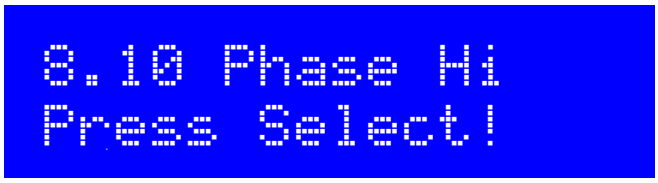
Pressing the left (select) button activates the signal generator on the configured frequency and displays a bar on the screen showing the measured audio amplitude at 700Hz. The Band Pass Filter trimmer capacitor should be adjusted for maximum measured amplitude. This process is described in the earlier section “Adjustment and alignment” at the end of the assembly part of the manual.



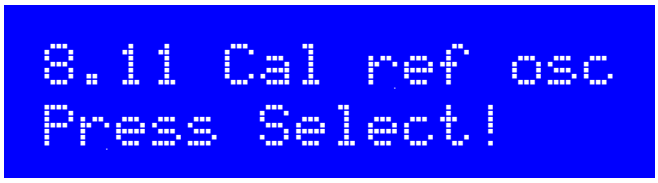
Pressing the left (select) button activates the signal generator on the configured frequency with an offset to put the received signal in the unwanted sideband. It displays a bar on the screen showing the measured audio amplitude at 700Hz. The I-Q balance trimmer potentiometer should be adjusted for minimum measured amplitude. This process is described in the earlier section “Adjustment and alignment” at the end of the assembly part of the manual.



Pressing the left (select) button activates the signal generator on the configured frequency with an offset to put the received signal in the unwanted sideband at the audio frequency configured (for example, 600Hz). It displays a bar on the screen showing the measured audio amplitude. The Low frequency phase adjustment trimmer potentiometer should be adjusted for minimum measured amplitude. This process is described in the earlier section “Adjustment and alignment” at the end of the assembly part of the manual.



Pressing the left (select) button activates the signal generator on the configured frequency with an offset to put the received signal in the unwanted sideband at the audio frequency configured (for example, 800Hz). It displays a bar on the screen showing the measured audio amplitude. The High frequency phase adjustment trimmer potentiometer should be adjusted for minimum measured amplitude. This process is described in the earlier section “Adjustment and alignment” at the end of the assembly part of the manual.

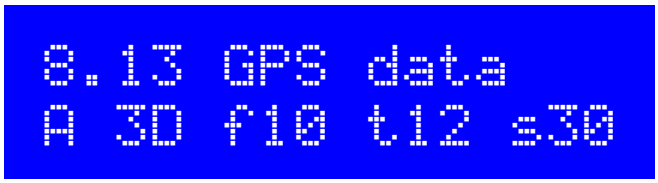


If you have connected a GPS receiver module such as the QRP Labs QLG1 GPS receiver http://qrp-labs.com/qlg1 with a one pulse per second (1pps) output signal, then when you press the left (select) button the microcontroller uses the 1pps as a frequency counter gate. The 27MHz reference value is divided by 4 and routed to the Timer1 input of the microcontroller, where it is counted for 4 seconds to obtain a frequency count. This value is stored in the EEPROM in the configuration parameter editable in menu item “8.5 Ref frq”.

The firmware calculates compensation adjustments to correct for the frequency error and ensure an output frequency precisely on target (typically with sub Hz accuracy). Naturally changes in ambient temperature will also cause the crystal oscillator frequency to change somewhat.

Using the GPS to calibrate the reference oscillator, system oscillator, or GPS info display (see later section), also automatically parses the serial data stream and sets the real-time clock and the Maidenhead Locator square (computed from latitude and longitude); these are used by the Beacon mode when using the radio as a WSPR beacon.

If you have connected a GPS receiver module such as the QRP Labs QLG1 GPS receiver http://qrp-labs.com/qlg1 with a one pulse per second (1pps) output signal, then when you press the left (select) button the microcontroller uses the 1pps as a frequency counter gate. It counts the 20MHz system clock internally for 4 seconds to obtain a frequency count. This value is stored in the EEPROM in the configuration parameter editable in menu item “8.6 System frq”.



When a GPS receiver (1pps and serial data) is connected and the alignment/calibration functions are enabled by pressing the left (select) button, data from the GPS is shown on the display. The five displayed info fields are to be interpreted as follows:

- A valid GPS Data (V would mean invalid data)
- 3D 3D fix (could be None, 2D or 3D)
- f10 GPS solution fix uses 10 satellites
- t12 GPS receiver is tracking 12 satellites
- s30 average signal strength of the 12 tracked satellites is 30.

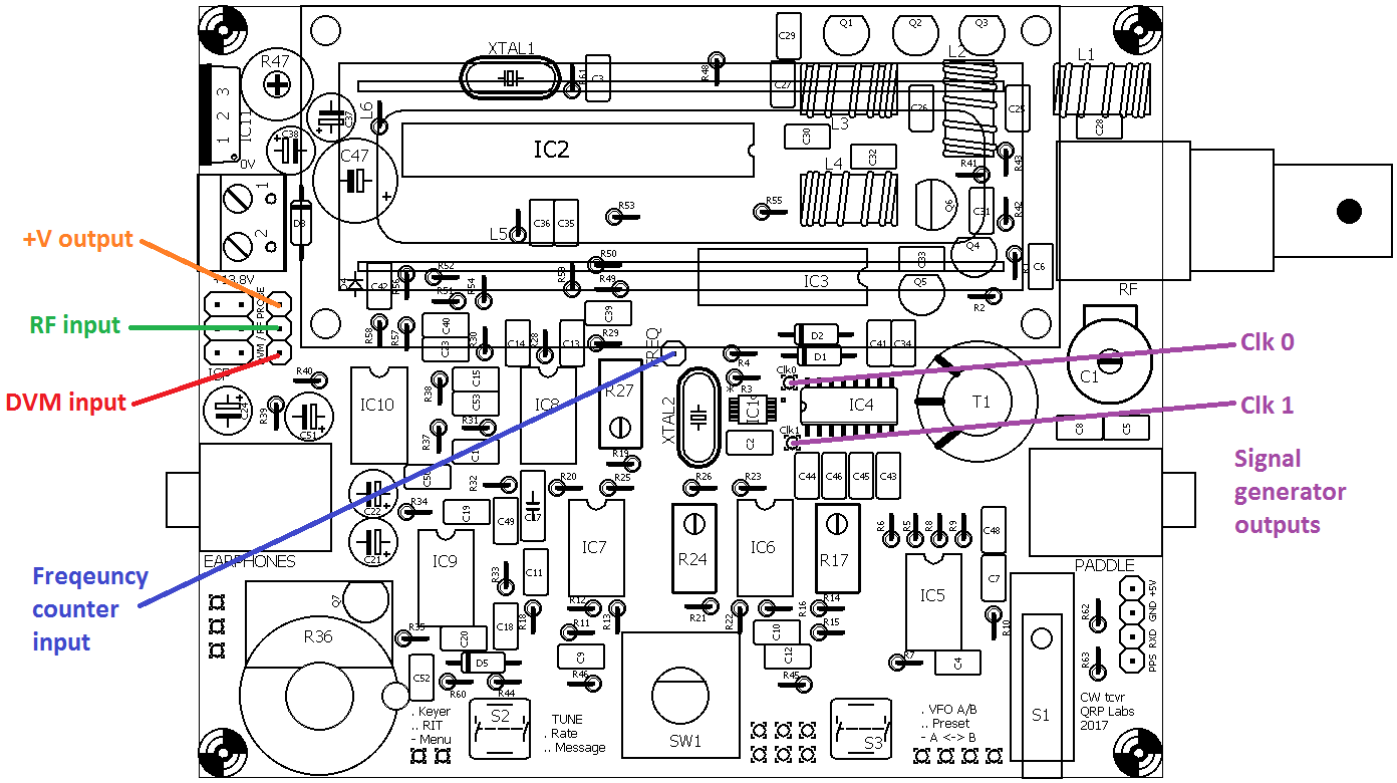
The GPS data menu item is for display of GPS information only. It can be useful to verify that the GPS is working properly and determine the best location for the GPS antenna, based on the number of tracked satellites and signal strength.

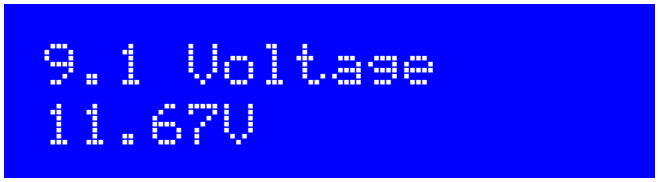
4.27 Test equipment

The test equipment menu provides several items of test equipment, which can be used to diagnose faults in your radio, and even for other testing purposes too!

The diagram below shows the connection points for the test equipment. **If you are attempting to measure external equipment or circuits, then you will also need to make a ground connection between the CW transceiver and the external circuit.**

These items of test equipment are described below. All except for the signal generator, are display-only items, with no corresponding stored configuration parameter.

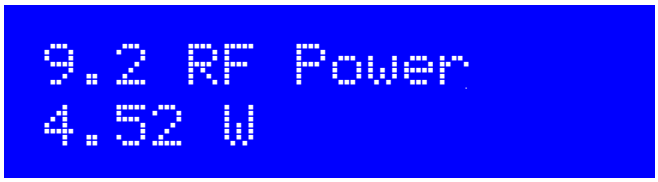




This the Digital Voltmeter (DVM) function. The measurable voltage range is 0-20V DC.

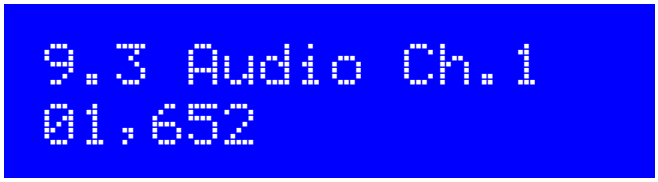
When the on-screen battery voltage display is used, you must connect the DVM input pin to the +V output pin (refer to previous diagram showing these connections).

In this example, a 12V power supply is being used to power the radio. The DVM input pin is jumpered to the +V output pin shown. The measured voltage of 11.67V is 12V minus the voltage drop over the reverse polarity protection diode D3.

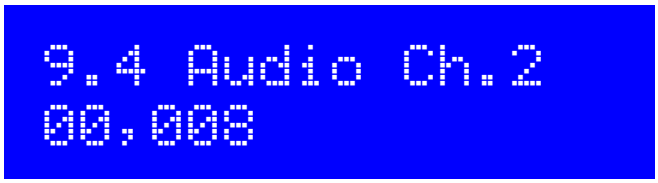


This the RF Power meter function. The measurable power range is 0-5W. The RF power measurement circuit uses a simple diode detector. There are non-linearities in the diode function, and differences from diode to diode; therefore, the measured power output is not highly accurate. However, it is certainly a very good indication and debugging tool.

Note that the RF Power meter and the DVM use the SAME Analogue to Digital (ADC) microcontroller input. You must not try to use the RF Power meter and the DVM at the same time! Ensure only one or the other is connected.



This item just displays the raw amplitude number calculated by the Goertzel algorithm for the audio channel 1, which is connected to the output of the audio amplifier. The value shown here will depend on the input signal level but also on the gain control. You can easily verify that as you turn up the gain control knob, the displayed value increases.



This item just displays the raw amplitude number calculated by the Goertzel algorithm for the audio channel 2, which is connected to the output of the phase nulling circuit. The value shown here is independent of the gain control. The value is much less than that measured on Audio Ch.1. This is because one ADC least significant bit equates to a voltage of about 5mV. The signal amplitude at that point in the receiver signal path is too low to produce much output from the ADC unless the received signal is very strong.

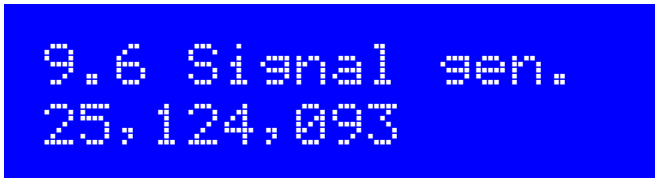
This is the frequency counter. The resolution is 10Hz, which results in an update rate of around 8 times per second approximately.

The frequency counter input is connected directly to the Timer1 input of the microcontroller. There is no pre-amplifier or level adjustment. The ATmega328P processor operates from a 5V supply. It expects the frequency counter input signals to be of an appropriate amplitude.

According to the ATmega328P datasheet, a “low” has a maximum input voltage of 1.5V and a “high” has a minimum input voltage of 3.5V. Therefore, the minimum amplitude signal to drive the frequency counter successfully would be 2V peak-peak centred on a 2.5V DC offset. Exercise great care to ensure that the voltage levels are correct, to avoid damaging the ATmega328P input pin.

Additionally, since the ATmega328P has synchronous timer inputs, the highest frequency which can be counted is limited to about 40% of the system clock (20MHz).

Therefore, this frequency counter has range of 0 to 8MHz. The upper frequency end of this range will only be achieved in the case of a nice tidy squarewave of adequate amplitude an 50% duty cycle. Lower quality signals will result in a lower upper frequency limit.



The signal generator function is switched off until you press the left button to select it. Then the cursor appears under the 10MHz digit. You can then adjust this number just like any other configuration parameter. Use the rotary encoder to increase or decrease the frequency. Press-and hold, then turn the rotary encoder, to change the tune rate (move the cursor left or right).

As you adjust the frequency, the output frequency of the synthesiser is tuned to match.

The output frequency range is from 3.5kHz to 200MHz. The Si5351A Synthesiser chip datasheet maximum frequency specification is 200MHz. However, in practice it has been found to still operate reliably up to almost 300MHz.

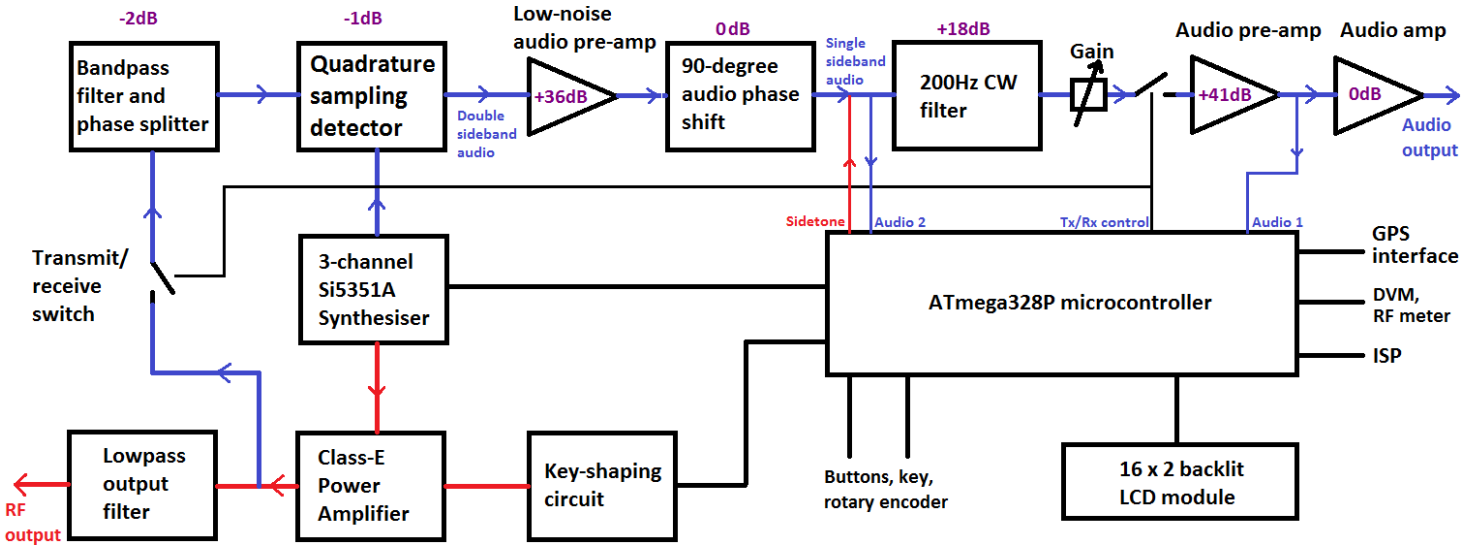
The output waveform is a squarewave with amplitude about 3.5V peak-peak. The output is at the Clk0 and Clk1 terminals (see diagram, above).

Note that the output is directly connected to the Si5351A Synthesiser chip's output pin. Take very great care not to short the output to ground or in any other way abuse this output! If you damage the Si5351A chip it is very difficult to replace

Note that where possible, the Si5351A's Clk0 and Clk1 outputs are operated in quadrature with a 90-degree phase offset. The relationship does not hold at frequencies below 3.2MHz and may not hold into VHF (To Be Determined).

5. Circuit design of the QCX

5.1 Block diagram and summary



This CW transceiver is a high performance, yet simple and low cost, analogue design. The transmitter uses a high efficiency Class-E amplifier which results in low current draw on transmit, and inexpensive transistors with no heatsinks.

The receiver is a direct conversion type utilising the famous high performance Quadrature Sampling Detector, also known sometimes as the “Tayloe Detector” or even “I-Q Mixer”. This receiver front end architecture has been used in the early Flex Software Defined Radios, Softrock series, Norcal NC2030 and many other SDR’s and other high performance front ends. The detector has very high third order intercept (IP3) and dynamic range, as well as low loss.

The resulting I & Q outputs are at audio baseband and go through a 90-degree phase shift network which cancels the unwanted sideband. A 200Hz bandwidth CW filter is followed by more amplification and drives common earphones.

The oscillators in the transceiver are provided by the modern Si5351A digital phase locked loop IC controlled by the microcontroller.

Permeating the entire design is microprocessor control by the ATmega328P microcontroller. This allows implementation of a large number of functions normally only found in radios costing 10-100x the price!

A really nice feature of the design is the built-in alignment and test equipment, which make it possible to build, align and even debug the assembly of the radio, all with NO additional test equipment.

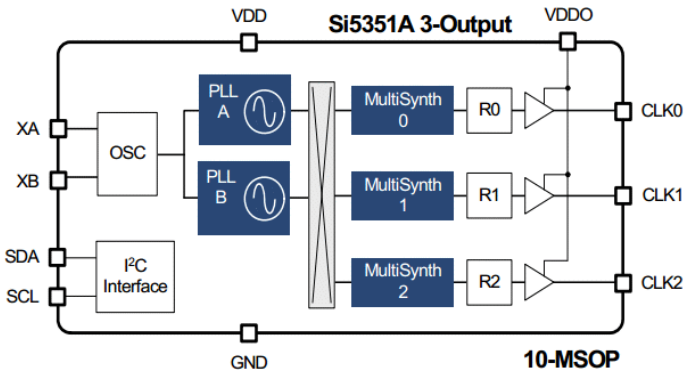
5.2 Circuit diagram

The complete circuit diagram (schematic) is shown on the previous page.

5.3 Synthesised oscillator

I always start with building the VFO of a radio. It was the hardest thing to get right. How to get that analogue LC-tuned VFO accurate, free of drift, free of chirp, tuning over the required range, and with mechanical gearing to be able to make fine frequency adjustments? A real challenge. Not any more! Now we have Direct Digital Synthesis (DDS) ICs and Digital Phase Locked Loop (PLL) ICs, inexpensive and easy to use, that solve all the problems.

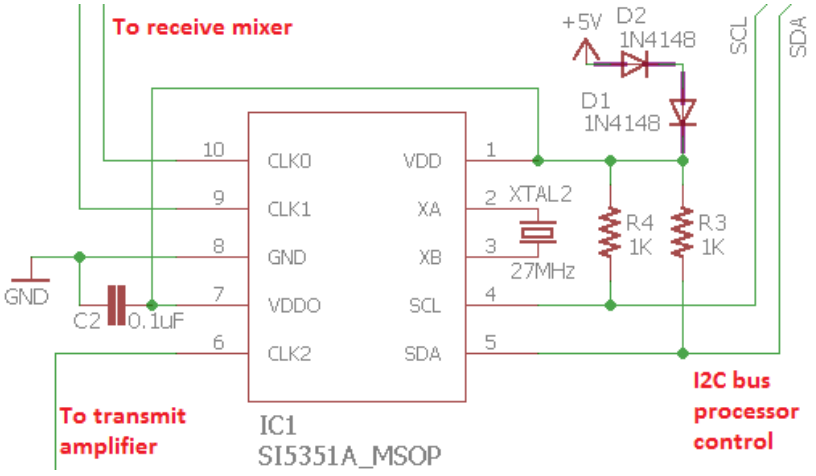
The Si5351A Synthesiser chip used in this design provides three separate frequency outputs, with a frequency range spanning 3.5kHz to 200MHz. The frequency stability is governed by the 27MHz crystal reference. Pretty stable, in other words.



The block diagram (right) is taken from the SiLabs Si5351A datasheet. Briefly, the 27MHz reference oscillator is multiplied up to an internal Voltage Controlled Oscillator in the range 600-900MHz (the PLL), then divided down to produce the final output frequency. The multiplication up and the division own are both fractional and so the frequency resolution is extremely finely controlled. The chip has two PLLs and three output divider units.

For best jitter performance, the Si5351A datasheet recommends the use of even integer dividers (no fractional component) in the MultiSynth dividers and in this CW transceiver design, this recommendation is followed.

The synthesiser section of the circuit diagram is shown here (right). The Si5351A datasheet dictates the use of a 25 or 27MHz crystal. QRP Labs has always used the 27MHz crystal in our designs because it allowed us to obtain precise 1.46Hz tone spacing for WSPR transmissions all the way up to the 2m amateur band (145MHz). Those calculations don't work out with the 25MHz crystal. This requirement doesn't apply to this CW transceiver design but economics of scale means there are advantages to sticking with the same component values, all other things being equal!



The Si5351A has a large number of internal 8-bit registers to control the synthesiser behaviour, and these are programmed by the microcontroller using the I2C serial protocol. 1K resistors R3 and R4 are pull-ups required for the operation of the bus at 400kHz.

The Si5351A chip requires a 3.0 to 3.6V supply (nominally 3.3V) but the rest of this transceiver's digital circuits operate with a 5V supply. For the reduction of complexity and costs, two 1N4148 diodes in series are used here to drop the 5V to a suitable voltage for the Si5351A. It works well.

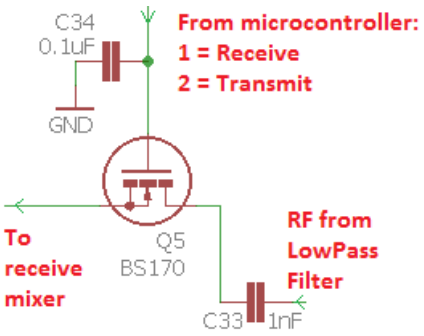
There are three outputs of the Si5351A synthesiser and these are all used to good advantage. The Clk2 output is used to feed the transmit power amplifier, and the Clk0/1 outputs are used to drive the Quadrature Sampling Detector (QSD) during receive. These outputs can be switched on and off under the command of the microcontroller. This provides an opportunity for some simplification because the Clk0/1 outputs can be simply switched off entirely during transmit. This relieves pressure on the transmit/receive switch. There just cannot be any reception during transmit because there is no oscillator input to the receive mixer. Conversely, the Clk2 output is switched off during receive.

A feature of the Quadrature Sampling Detector is that either the RF input, or the LO input, must provide two paths in 90-degree quadrature. This is normally applied at the Local Oscillator where it can be easily controlled for best performance. So, two oscillator signals are required, with the same frequencies but a precise 90-degree phase offset. Generating this quadrature Local Oscillator signal is always difficult. Analogue phase shift circuits have limited accuracy. Often a divide-by-4 circuit is used, to produce quadrature oscillator outputs from an oscillator input at 4x the reception frequency. This also creates challenges particularly as you try to increase the reception frequency to cover higher bands. For example, on 10m e.g. 30MHz, a local oscillator at 120MHz is required and the divide-by-4 circuit must be able to operate at such a high frequency. Devices such as the 74AC74 can do so, but pushing it higher into the 6m band cannot be done with the 74AC74.

The Si5351A has a phase offset feature, which is not really very clearly described in the SiLabs documentation. However, QRP Labs has perfected the technique to put two of the Si5351A outputs into precise 90-degree quadrature, which is maintained without tuning glitches as the frequency is altered. It's a nice development because it eliminates one more circuit block (the 74AC74 divide-by-4 circuit), again reducing complexity and cost. To the best of my knowledge this the first time the Si5351A has been implemented in a product directly driving a QSD with two outputs in quadrature (no divide-by-4 circuit).

5.4 Transmit/Receive switch

Since the receiver is entirely disabled during transmit, because of the absence of any local oscillator signals to the Quadrature Sampling Detector, the demands on the transmit/receive switch are considerably reduced. Now the circuit does not have to provide the massive amount of attenuation necessary to prevent the transmitter from overloading the receive circuits. All it has to do is provide a reasonable amount of attenuation, enough to stop the 5W signal (45V peak-peak) from damaging the receiver input mixer.

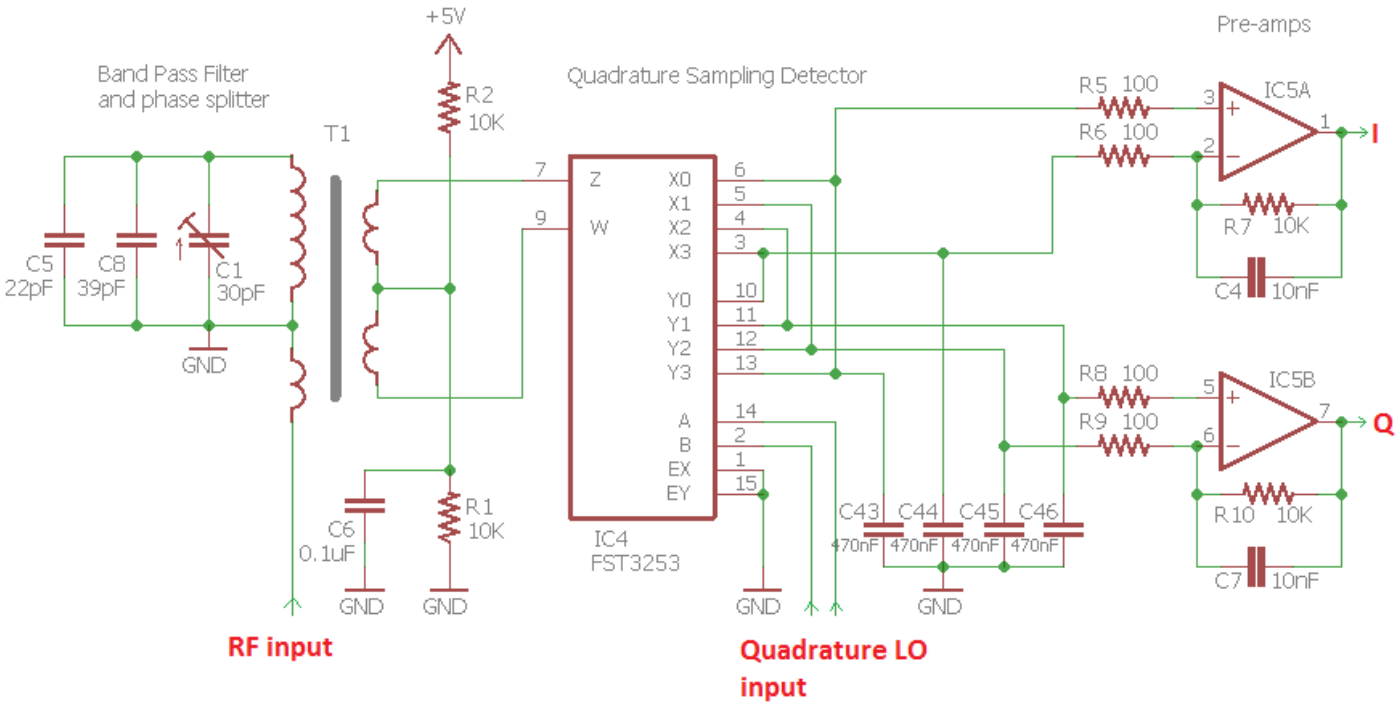


The transmit/receive switch is implemented by a single BS170 MOSFET. The source is at DC ground (via the primary of input transformer T1). The control signal from the microcontroller switches the MOSFET on or off. Interestingly, capacitor C34 close to the MOSFET gate is found to be necessary to prevent inductive pickup of the 5W RF from partially switching on the MOSFET.

The switch wouldn't provide enough attenuation to mute an operating receiver; but during receive, our receiver isn't operating; all the switch has to do is protect the Quadrature Sampling Detector from seeing 45V peak-peak which would destroy it.

5.5 Band Pass, Phase Splitter, QSD and pre-amps

Since the band-pass filter, Phase splitter, Quadrature Sampling Detector and pre-amp circuits are so tied up together, I am going to consider them all together in this section.



This circuit implements an input band-pass filter and double-balanced Quadrature Sampling Detector with low-noise pre-amps. Yet it does this with a low parts count, and resulting low complexity and cost. The FST3253 is a dual 1:4 multiplexer which is often seen in QSD circuits. It has fast switching times and very low on resistance of only a few ohms. The input signal is switched by the quadrature LO to each of the four integrating capacitors C43-C46 in turn, for 90-degrees of the RF cycle each. The result is that the audio difference (beat) between the RF input and LO input appears across each of the four integrating capacitors, with four phases at 0, 90, 180 and 270 degrees.

The operational amplifier IC5a takes the difference of the 0 and 180-degree outputs and amplifies it, resulting in the I output of the QSD. Similarly, IC5b differences the 90 and 270-degree outputs to produce the Q output.

The combination of the relatively large 470nF capacitors and the low source resistance results in a fast roll-off of the audio response. This is effectively a very narrow band pass filter since any incoming RF more than a few kHz away from the LO frequency is greatly attenuated. The QSD is therefore inherently a very high performance mixer design with high third order intercept and dynamic range, and low loss (0.9dB).

The FST3253 dual switch is often connected with the two switches simply paralleled together (which does half the switch ON resistance). But I prefer the double-balanced mixer configuration which provides higher performance. The double-balanced configuration requires two RF inputs 180-degrees out of phase (opposite to each other).

Despite the high IP3 and dynamic range, it is still prudent to provide some input band pass filtering to protect the mixer from strong out of band signals. In this CW transceiver design, the T1 transformer provides a simple solution to all of these problems with a very low parts count.

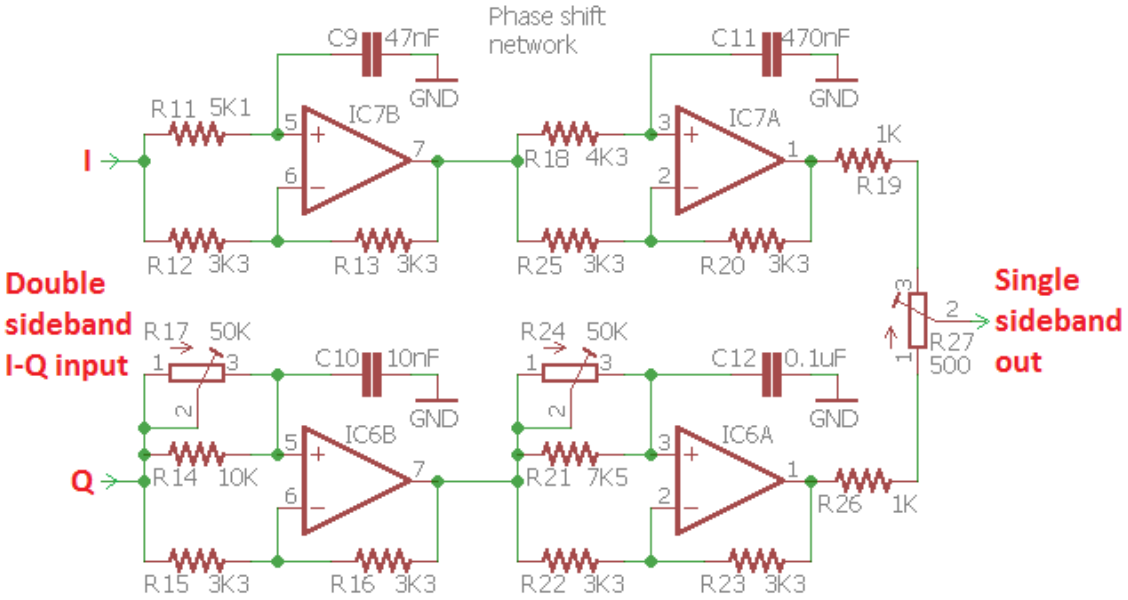
The primary couples the incoming RF into the two secondary windings which feed the double-balanced detector. One end of the primary is grounded which neatly keeps the DC potential of the input at ground, so the transmit/receive switch is easily implemented by a single MOSFET (see previous section). The two secondaries are connected as a centre-tapped single winding, which means that the outputs have 180-degree phase difference as required.

The secondary “centre-tap” is connected to a DC bias formed by R1, R2 and C6 at mid-rail i.e. 2.5V. This simple bias does not source or sink any significant current due to the balanced nature of the system, therefore no buffering is required. The DC bias feeds through the pre-amps, and into later stages – including the 90-degree phase shift network and the first three op-amps of the CW filter. It is a great benefit not to have to AC couple each stage with coupling capacitors, and then bias each stage individually. In this circuit, the same DC bias flows through all the way from this centre-tapped input transformer. This reduces component count and - you guessed it – complexity and cost. Another benefit may be that since much of the receiver signal path is DC coupled, it might be easier to reduce the inevitable “thumps” on switching between receive and transmit.

Finally, the band pass filter is implemented by a fourth winding on the same transformer T1, with some fixed capacitors and a trimmer capacitor forming the resonant circuit. It is only a single resonant circuit band pass filter so has limited stop-band attenuation, but it does have the benefit of low parts count, and simplicity of adjustment due to the single adjustment control.

5.6 90-degree audio phase shift

By this stage the I and Q outputs are each double-sideband, and we need to process them to demodulate single sideband.



The circuit used here is an active two-path all-pass phase shift network based on four operational amplifiers. The circuit is based on the same phase shift block as the Norcal NC2030 http://www.norcalqrp.org/nc2030.htm

In the real world, nothing is perfect – there are component tolerances to think about. The unwanted sideband suppression is maximised when the amplitude of the two paths is equal, and the 90-degree phase shift is accurate.

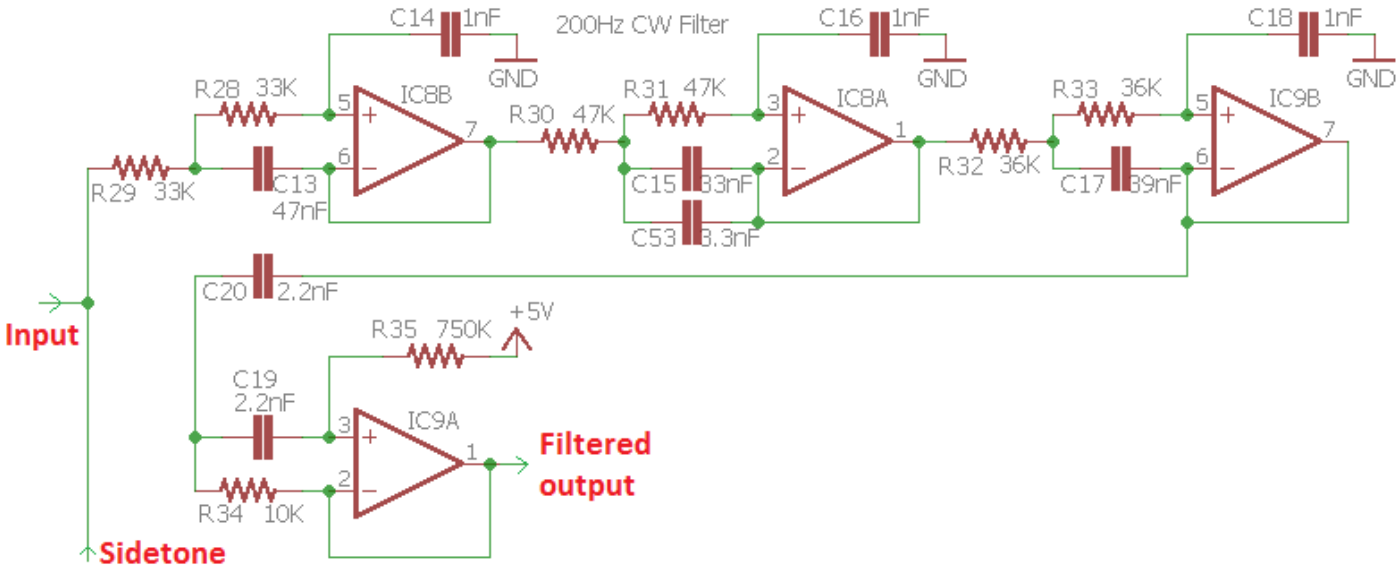
To improve the accuracy of the 90-degree phase shift, R17 and R24 allow adjustment of the phase shift at higher and lower audio frequencies respectively.

R27 allows adjustment of the balance between the I and Q channels, to equalise the amplitude from each path.

This CW transceiver kit includes built in alignment and test equipment, with a signal generator that can inject a test signal into the receiver input. It makes it easy to perform these adjustments, as described previously.

5.7 CW filter

The CW filter used in this receiver has a 200Hz bandwidth. The circuit is based on the HI-PER-MITE CW filter kit design by David Cripe NM0S, available from the Four State QRP group: http://www.4sqrp.com/HiPerMite.php (thanks David for permission to use it here). This is a high performance circuit specifically designed to avoid objectionable ringing.



There are three stages of low-pass filtering and one stage of high-pass filtering. The first three stages retain the 2.5V “midrail” bias all the way through from the input transformer T1. The final stage IC9A is biased using the 5V supply (avoiding a few extra components to create a real 6V midrail at half the supply).

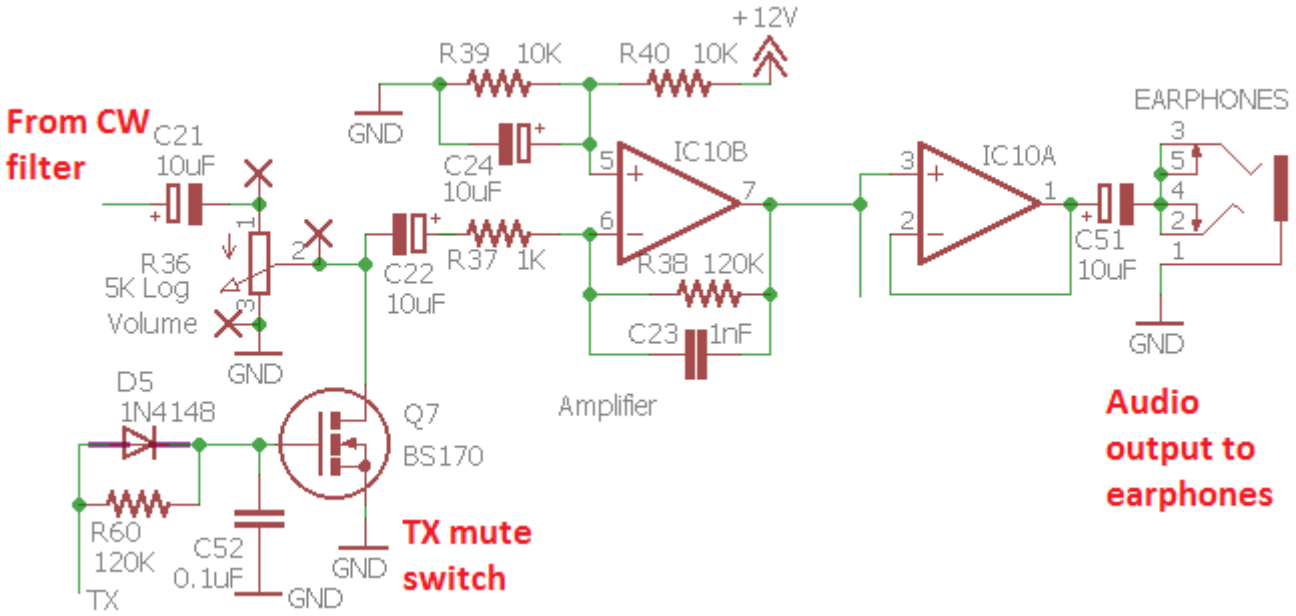
Sidetone is generated by the microcontroller and is a squarewave. To make it sound nice and clean, the sidetone injection is done at the input to the 200Hz CW filter, which cuts off any of the squarewave harmonics leaving a clean 700Hz sidetone.

The CW filter also provides a measured 18dB of gain.

5.8 Audio amplifier

The final stage in the receiver signal path is the audio amplifier, to drive earphones at a comfortable listening level.

R36 is a logarithmic potentiometer used as the gain control. With the wiper fully clockwise the receiver is at full volume. As the potentiometer is turned anticlockwise it forms a potential divider which attenuates the audio signal from the CW filter output.



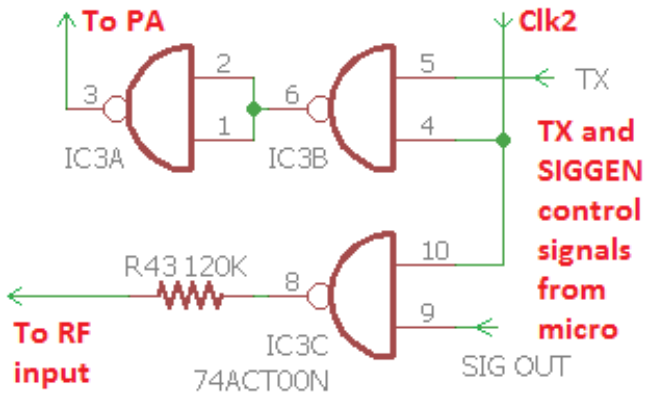
There is also a TX mute switch formed by Q7, another BS170 MOSFET. This was a late addition to the design: despite all attempts, I could not remove the nasty click on receive/transmit switching. The mute switch helps to attenuate it. The switch is operated by the microcontroller Receive/Transmit switch output. When the BS170 switch is on, it has a low resistance to ground which greatly attenuates the audio signal.

To reduce the audio “thump” when the transceiver is switched from transmit back into receive, the mute switch needs to remain switched on for a short while after the receiver is switched back on. A small wait while the thump subsides. This delay is achieved by the R-C network formed by R60 and C52. This would also introduce a delayed switch-on of the mute switch, which would allow the thump when switching to transmit to be heard. To prevent this, diode D5 was added, which bypasses the resistor R60 at the receive-to-transmit switchover. It ensures that at the receive-to-transmit event, the mute switch is enabled instantly; but on the transmit-to-receive switchover there is a short delay.

IC10B is a simple amplifier configured for 41dB of gain. The ½-V midrail bias is created by R39, R40 and C24. Using the 5V power line as “midrail” was found to add too much noise. Finally, IC10A is a simple unity-gain buffer. Although it is just an op-amp it is found to be perfectly adequate for driving standard earphones.

5.9 Transmit signal routing and PA driver

The 74ACT00 is a quad NAND logic gate. The input threshold voltage for a binary "1" is 2.4V which means that the gate is easily switched on by the ~3.3V peak-peak squarewave output from the Si5351A. The output of the 74ACT00 is 5V peak-peak, perfect for driving the BS170 MOSGETs in the Class-E PA into saturation.



The Clk2 signal from the Si5351A is used as the transmit oscillator as previously mentioned. It would have been easy to enable/disable the Clk2 output in software in the Si5351A chip configuration. However, this transceiver design also includes the built-in signal generator feature, for aligning the Band Pass Filter and adjusting the I-Q balance and phase adjustment controls. So, some of the spare gates in the 74ACT00 are used to switch the signal generator on/off and the RF Power Amplfier (PA) signal on/off, separately.

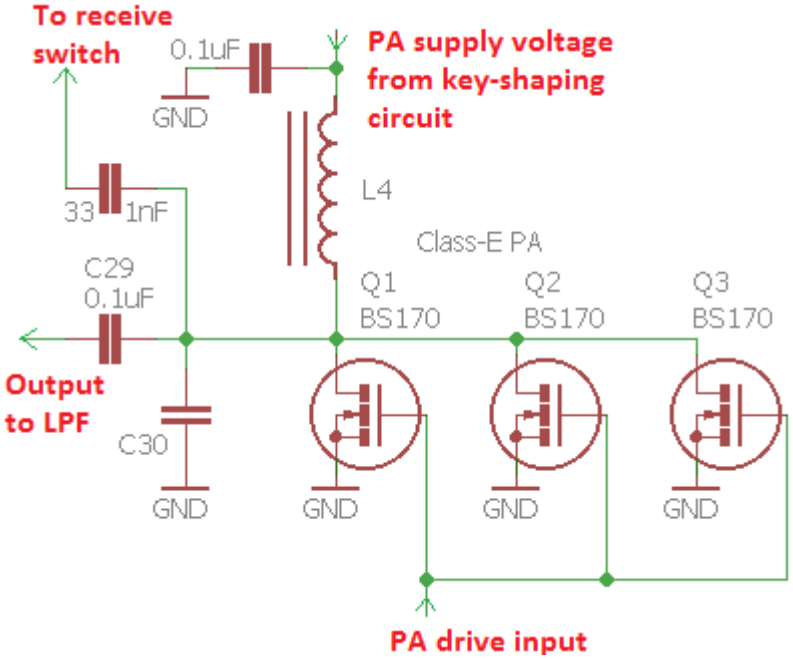
When the SIG OUT control line from the microcontroller is high, the Clk2 signal is enabled as signal generator, and routed via a 120K resistor straight to the RF input of the transceiver.

When the TX control line from the microcontroller is high, the Clk2 signal is routed to the PA. The final inverting gate IC3A is added to make sure that when the TX gate IC3B is off, the driver voltage presented to the BS170 gate is low, so the transistors are off.

5.10 Class-E Power Amplifier

A Class-E power amplifier is a wonderful thing. It has a very high efficiency, sometimes over 90%. This has several important benefits:

a) Since not much power is dissipated, we can use smaller (and cheaper) transistors
b) So little power is wasted as heat that the requirement for a heatsink is reduced or eliminated
c) During transmit the radio requires less current, so the drain on a battery is less – important for people who want to operate portable.



A Class-E Power Amplifier contains a resonant circuit at the frequency of operation, so it is only suitable for single-band use. A lot has been written about Class-E, much of it is very technical and mathematical.

Some excellent background reading are two papers by Paul Harden NA5N:

http://www.aoc.nrao.edu/~pharden/hobby/_ClassDEF1.pdf and
http://www.aoc.nrao.edu/~pharden/hobby/_ClassDEF2.pdf

Paul NA5N describes two defining features of Class-E:

1) Use of a square-wave drive to reduce switching losses: the transistors are either on, or off… no lossy region in between
2) Reducing the effects of the transistor capacitances. Class-E has a resonant tuned circuit. The capacitance of the transistors, normally an unpleasant lossy aspect, is now a part of the tuned circuit.

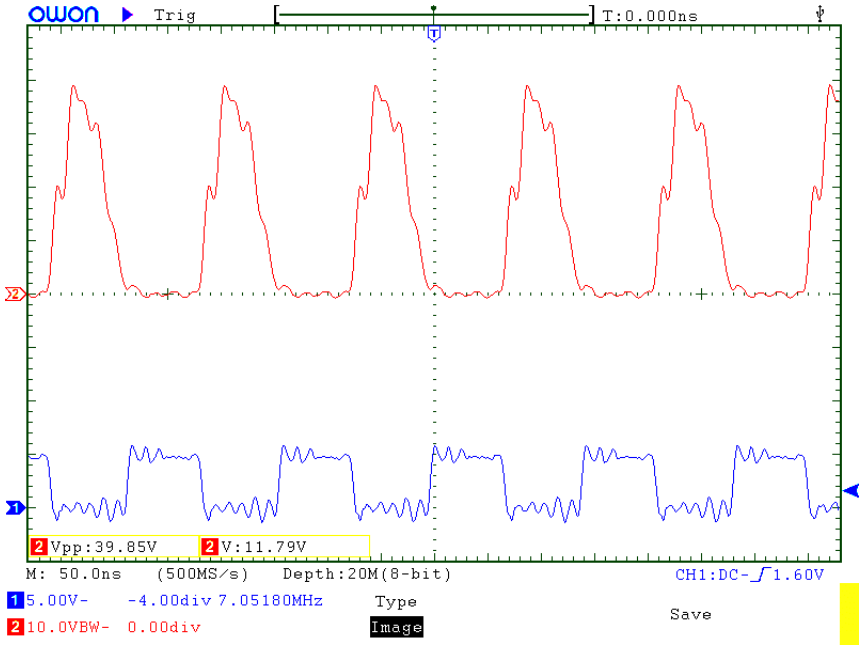
Class-E also has a reputation for being difficult to achieve. All those intense mathematics Google will help you find, don't help. In reality, once you realise the secret – it is not so difficult. Calculation of the impedance of a resonant circuit is simple, and there are many online calculators which will do the job for you. For example, http://toroids.info/T50-2.php which allows you to type in the operating frequency, and the desired resonant circuit impedance. Then the calculator computes the required inductance, capacitance, and the number of turns required for a certain toroid (in our case we use a T50-2).

The Class-E design process is simple. Choose the output impedance. We choose 50-ohms, because this is the input impedance of the Low Pass Filter we will use. The online calculator will tell you what inductance is needed, and how many turns to wind on the toroid. The online calculator also tells you the required capacitance to bring it to resonance at the operating frequency. Here we resort to experiment, because it is a little difficult to know what the output capacitance of the transistor is. The device capacitance varies depending on supply voltage and whether it is on or off. A simple experiment is required, adding different small capacitances to the circuit, and measuring the efficiency (measure supply voltage and supply current to calculate power input; then measure RF power output. Divide one by the other to get the efficiency). It is easy to find what additional capacitance is required to peak the efficiency. The resonance is quite broad and non-critical.

In this implementation, three BS170 transistors are used in parallel. The BS170 is inexpensive and small, but is rated for 500mA drain current and up to 830mW of dissipation. Per device. Three in parallel provides plenty of capability to achieve a 5W output on a single band.

There are always minor variations between device characteristics from one transistor to the next. If these were bipolar NPN transistors, we would not be able to parallel them in this way. If one transistor takes more of the load and starts to heat up, its resistance further decreases and this causes it to get even hotter. This process is known as "thermal runaway" and results (quickly) in destruction of the transistor. Emitter resistors are used to help balance the load. But with MOSFETs, their resistance INCREASES as the temperature goes up – so there is an inherent self-balancing when multiple devices are used in parallel, without any need for additional balancing resistors which would increase component count and waste some power.

This oscilloscope screenshot shows the classic Class-E waveform. Please ignore the ringing due to poor set-up of the 'scope probes etc. The lower (blue) trace is the 5V squarewave at the gate of the BS170 transistors. The upper (red) trace is the voltage as the BS170 drain. It peaks at approximately 40V in this example. This measurement was done with 12V supply and on 40m (7MHz).

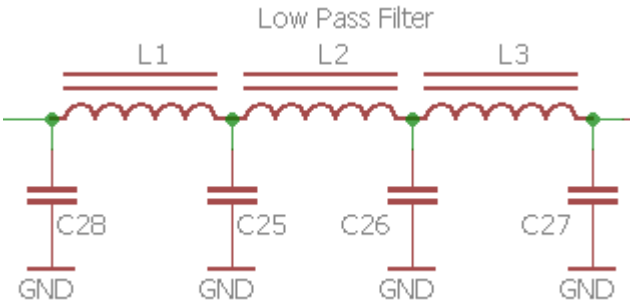


The important point to note is that when the BS170 are switched ON (the gate voltage is 5V), the drain voltage is zero. When the BS170 is OFF the gate voltage pulses nicely to a large amplitude. Class-E!

The summary: Class-E is actually quite easy to achieve in practice! Perhaps all the complicated mathematics might help to squeeze out another % or two of efficiency. But for practical purposes, it's a wonderful building block to use in a single-band CW transceiver.

5.11 Low Pass Filter

The transmitter output is rich in harmonics and must be followed by a good Low Pass Filter, to attenuate the harmonics and satisfy regulatory compliance.



The standard, well-proven QRP Labs Low Pass Filter kit http://qrp-labs.com/lpfkit is used here. To save space and cost, the components are installed directly on the PCB, not on a plug-in board.

It is a 7-element filter design originally by Ed W3NQN then published for many years on the G-QRP Club web site's technical pages.

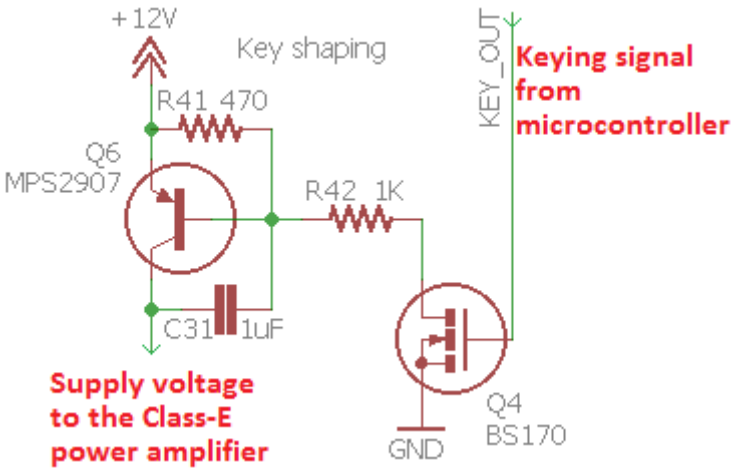
5.12 Key-shaping circuit

A hard-keyed CW transmitter generates clicks many hundreds of Hz away from the transmitted signal that can annoy users of adjacent frequencies. This is purely a consequence of the mathematics of the Fourier transform and is unavoidable. Any time you switch a signal instantly on or off, you WILL splatter energy onto unwanted nearby frequencies.

To combat this, any good CW transmitter should include an RF envelope shaping circuit to soften the key-down and key-up transitions. The ideal envelope shape is a raised cosine, but this is difficult to implement without significantly increasing the complexity of the circuit.

The simple key-shaping circuit used here uses only a few components but produces good results.

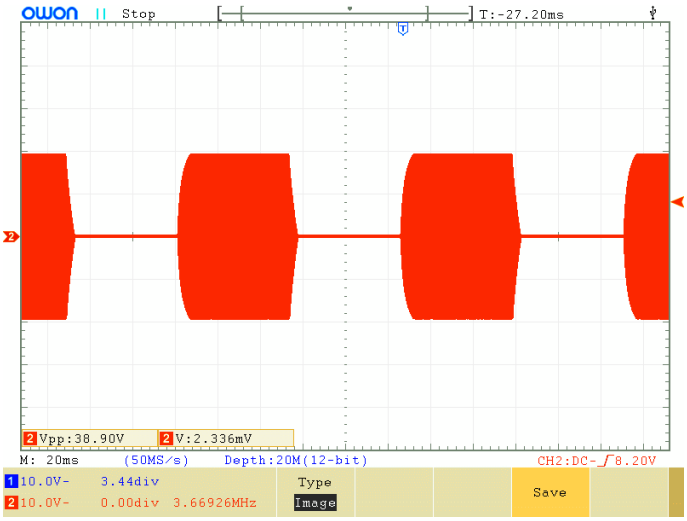
This circuit was derived by one published by Don Huff W6JL, see https://www.qrz.com/db/W6JL/ though as he says, "*this integrator-type keying circuit is found in many published homebrew designs over the past 40 years or so, so it is nothing new*". It uses a PNP transistor (Q6) and R-C integrator circuit. Don W6JL uses this key-shaping circuit to drive a 600W Power Amplifier.

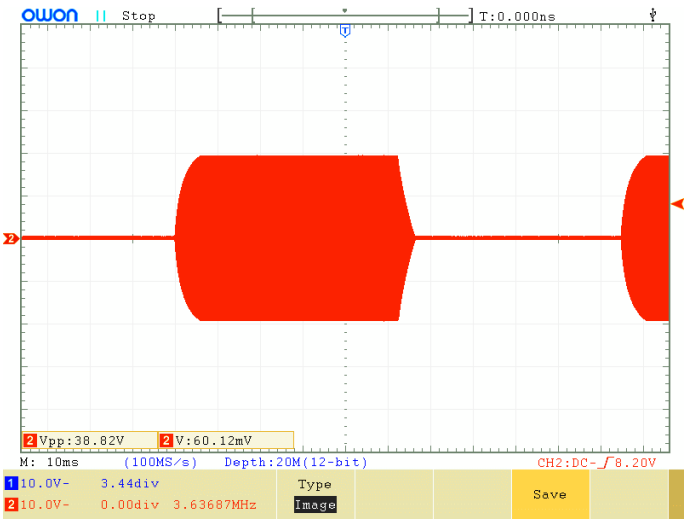


On key down the Q4 switch is "closed" by a high signal coming from the microcontroller. In a really simple transmitter, Q4 could just be replaced by a straight Morse key to ground! But in our case, the microcontroller implements automated stored message sending, beacon modes, and Iambic keyer – so we need the microcontroller to be the boss of everything. The microcontroller reads the state of the straight key or paddle, and processes it to produce a key output. When in straight key mode the microcontroller transfers the signal straight through from the key input, to the key output control line – but in other modes the processor must generate the keying signal.

The component values set the rise and fall time. With the components shown, the rise and fall time is about 5 milliseconds.

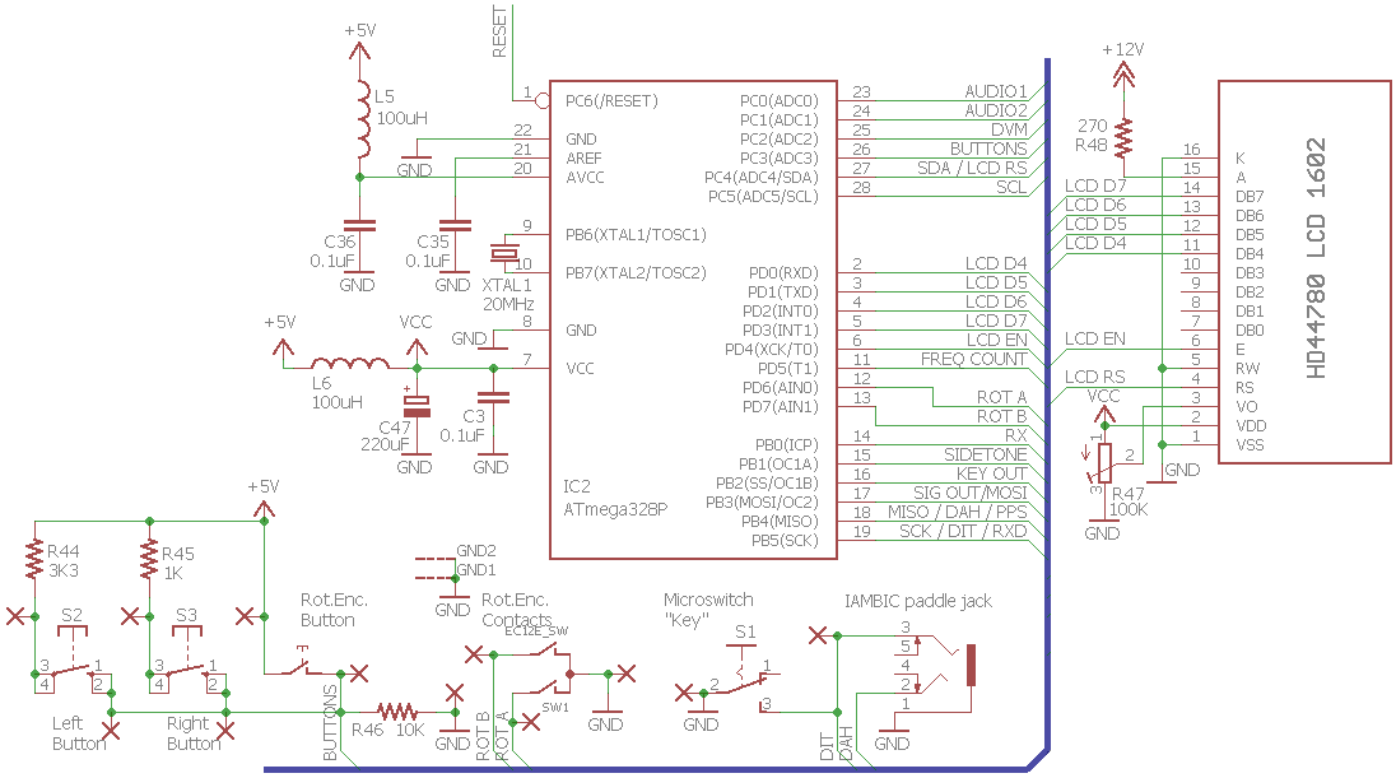
The following oscilloscope screenshots show a 40m band (7MHz) transmission, keyed with a continuous series of CW dits at approximately 24 words per minute. The amplitude is approximately 3.8W into a 50-ohm dummy load (with 12V power supply).





5.13 Microcontroller

The ATmega328 microcontroller circuit controls many aspects of this transceiver. Below is this section of the transceiver circuit. Several points are worthy of discussion.



ATmega328P processor

The ATmega328P was chosen because it has enough processing power and I/O to handle all the tasks required here. It is also common and inexpensive, and lots of QRP Labs products already used it, bringing economies of scale in both the kit preparation and the coding. The processor is operated at its maximum rated 20MHz system clock speed.

The code is all written in C and is not open source. While the same ATmega328 processor is used in the popular Arduino Uno products, there is no relation between code written for the Arduino environment and the custom code written for this CW transceiver.

Tuning clicks

Some constructors of radio receiver projects that use the Si5351A report loud clicks every time the frequency is changed. The cause of these clicks is one or both of two underlying issues:

a) Faults in the software configuring the Si5351A
b) Power line or radiated noise from the microcontroller/LCD back into the sensitive receiver

The first of these is not an issue here since we have already extensive experience using the Si5351A and have perfected its configuration.

The second issue is important to address. Every time the microcontroller updates the Si5351A configuration to cause it to change frequency, it typically also writes the new frequency to the LCD. There is a burst of activity in the microcontroller, and on the digital control signals to both the Si5351A and the LCD. The LCD controller chip will also be doing some work to effect the changed display. All of these digital transitions can radiate noise into the receiver front end. Changes in power consumption cause noise on the supply lines which can also be converted into noise detected in the receiver front end.

To combat the radiation issue, the ATmega328P microcontroller is sited at the back of the board, right under the LCD module. The tracks between the LCD module and the microcontroller are therefore kept as short as possible, to minimise radiated noise.

To keep noise out of the supply, the 5V supply to the microcontroller and LCD module is filtered by 100uH inductor L6 and 220uF capacitor C47 (may be supplied as 470uF, even better!).

In combination, these measures ensure that there are no “clicks” in the audio when tuning the receiver; just a small “flutter” as I call it, which is a natural consequence of the sudden change in frequency (Fourier rules).

Liquid Crystal Display module

The transceiver uses an HD44780-compatible LCD Module with 16 characters by 2 rows. The LCD is operated in the 4-bit mode in order to minimise the I/O pins used. No data is read back from the LCD which means the Read/Write pin can be grounded. In total only 6 I/O pins are used for writing to the LCD.

The usual contrast adjustment trimmer potentiometer is R47 and must be set to obtain a readable display.

The LCD backlight consumes about 30 or 35mA of current. The backlight could be connected directly to the 5V supply but this would somewhat increase the power dissipation of the 7805 regulator. In order to avoid overheating the regulator, this backlight is powered instead directly from the +12V rail via R48, a 270-ohm resistor. This resistor value was chosen so that over a supply voltage range of 7 to 20V the backlight brightness still appears reasonable. If you want a reduced brightness display, you could increase the value of R48.

Sidetone

In this transceiver, the sidetone is generated by Pulse Width Modulation using the ATmega328’s Timer1 peripheral. The frequency is configurable in the software via the configuration menu, and so is the volume. In order to control the volume, the microcontroller adjusts the duty cycle from 50% (maximum volume) down to under 1% (for minimum volume).

The sidetone is injected into the receiver path via a 3.3K resistor at the input to the CW filter. The sidetone generated by the microcontroller is a squarewave, rich in harmonics. As the volume is reduced, the duty cycle percentage drops and the amplitude of the 700Hz fundamental tone also drops. There are many harmonics of course, and the CW filter does a great job of removing these, so what is left in the earphones is a pleasant and pure 700Hz sinewave. This is why the sidetone is injected at the CW filter INPUT.

During transmit, when the sidetone is operational, the mute switch Q7 is also closed – but there is enough leakage through the imperfections of this switch that the sidetone gets through anyway. The 3.3K sidetone feed resistor R59 is chosen to pump enough signal through that it overcomes the attenuation of the mute switch. Without the mute switch, R59 would be a much higher value.

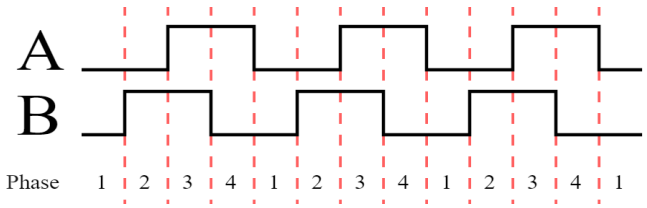
Key paddle, rotary encoder switch and buttons

The microcontroller keeps an eye on all the buttons, key paddle inputs, and rotary encoder switches. When button or switch closures occur as the operator activates a control, the microprocessor responds immediately as required.

The onboard microswitch “key” is wired in parallel with one of the paddle inputs. The paddle inputs, and the rotary encoder switch, are read using dedicated microcontroller I/O signals.

All mechanical switches exhibit switch bounce, where the switch contacts generate multiple transitions for a short time when the switch is activated. It is common to see in many projects, resistor-capacitor networks to debounce switches (including the rotary switch). Simple debounce circuits involving a resistor and a capacitor inevitably involve a compromise when choosing the R-C time constant. It is easy to miscalculate and make the time constant too short (bounce noise still gets through) or too long (rapid switch closures are missed). In some cases it is impossible to find the sweet spot in between these two extremes.

In my opinion, resistor/capacitor debouncing is a poor solution to the problem, when the circuit contains a microcontroller. It is easy to debounce the switch edges in software! This allows you to control time-constants or other debounce logic much more precisely. Of course, it saves those additional resistors and capacitors too, which all helps reduce the cost and complexity of the kit! This is the reason why in this kit, you will not see any resistor or capacitor debouncing of any of the controls. Everything is done in the software.



The rotary encoder is debounced using a state machine, rather than any timing loops. The rotary encoder produces two switch-closure outputs which have a 90-degree (quadrature, again) phase shift. The microcontroller can monitor these transitions and determine the number of “clicks” of the rotary encoder, and the direction the knob was turned in, and at the same time debounce the switch transitions.

Another unnecessary component often seen is a pullup-resistor on a switch signal to a microcontroller, so that when the switch is open (not pressed) the microcontroller sees a “high” voltage. This is unnecessary because modern microcontrollers such as the ATmega328P all contain configurable internal pull-ups!

I had a little more trouble when it came to the Left, Centre (shaft of the rotary encoder) and Right push-buttons. Despite thinking that the microcontroller had plenty of I/O signals available, when I came to implement all the features I had in mind, I realised there weren’t enough I/O signals to read the buttons!

The solution was to analogue-multiplex all three buttons onto a single input signal to the microcontroller, which is one of the Analogue to Digital Converter (ADC) channels. No microcontroller internal pull-up is used because I need to have precise control over the voltage levels. The input signal is pulled low by a 10K resistor R46. One side of all three buttons is connected to the I/O pin. The other sides of the buttons are connected to 5V via different resistors: 3.3K (R44) for the left button, 1K (R45) for the right button, and direct connection for the centre button. When one of the buttons is pressed, the resistors form a potential divider that sets the voltage to the microcontroller depending on which button is pressed. Some calculation results in the following table of voltages depending on which button is pressed:

Button pressed	**Voltage**
None	0.00V
Left	3.76V
Centre	5.00V
Right	4.55V

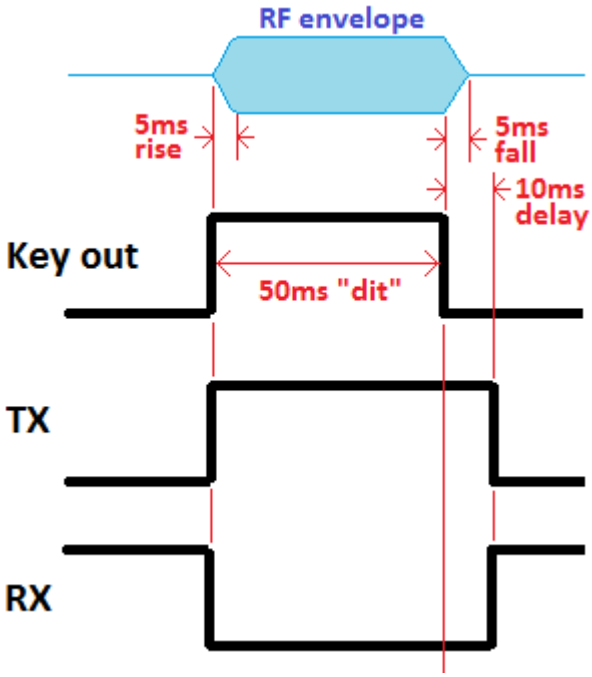
In all three cases, the voltage when a button is pressed, is higher than the 3V logic “1” threshold of the microcontroller. I am able to use a pin-change interrupt to detect that a button has been pressed, then read the ADC channel 3 and compare the measured voltage to the table, to determine which button was pressed.

It’s a nice trick for reading multiple buttons on a single ADC input, and it would work also for a larger number of buttons! Each one just needs a different resistor value and eventually, some care would need to be taken to ensure that the voltage differences could be read reliably, not masked by ADC noise or component inaccuracies. For three buttons, none of these problems arise.

TX/RX Switch control, and Key Out signals

As already discussed, the Key Out signal either reflects directly the state of a straight key, in Straight keyer mode, or it is a processed keyer signal when using the Iambic keyer modes or Beacon function of the transceiver. The Key Out signal is generated by the microcontroller with precise timing in the Beacon and Iambic keyer modes. It is routed to the RF envelope key-shaping circuit discussed previously.

The Transmit/Receive switch must remain in “transmit” state for a short time after key-up, in order for the RF envelope of the key-shaping circuit to drop gently down to zero, which takes approximately 5ms. Due to this, the microcontroller implements a 10ms delay between key-up and switching the radio back to receive mode.



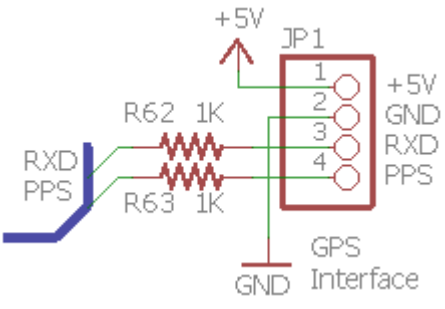
The diagram (right) illustrates the relationship between these signals, for an example 24 words per minute “dit”. The Key out signal has a “high” period of 50ms exactly. The ramp-up and ramp-down of the RF envelope has 5 millisecond (approximately) rise and fall times. The “RX” control line generated by the microcontroller switches on the receiver (allows RF through to the receive mixer) when it is “high”. It is held in the “low” (transmit) state for 10ms after key up completes.

The “TX” signal is the inverse of the “RX” signal, and it switches the gate of the audio mute switch Q7 during transmit. One of the NAND gates IC3D is used as the inverter to create the “TX” signal from the microcontroller’s “RX” output.

5.14 Optional GPS interface

The GPS was a late addition to the design. It is added to facilitate several useful features:

- Calibration of the 27MHz reference oscillator
- Calibration of the 20MHz system clock
- For WSPR, discipline of the frequency (drift correction)
- For WSPR, setting and discipline of the real time clock
- For WSPR, setting the Maidenhead Locator square



The optional GPS interface is provided by a 4-pin header at the bottom right of the board, next to the 3.5mm socket for the keyer. The pinout of the 4-pin header exactly matches the one on the QRP Labs Ultimate3S QRSS/WSPR transmitter kit, and the QRP Labs QLG1 GPS receiver kit. This makes connecting the radio to the QLG1 GPS kit very easy, if you wish. However other GPS modules could also be used. The following requirements of the GPS module must be met:

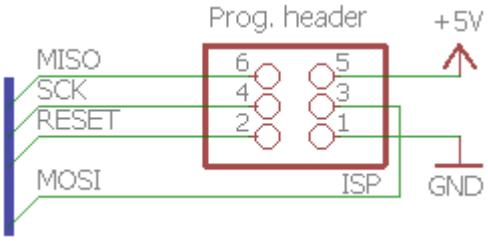
- Positive-going (leading edge) 1 pulse per second signal with a reasonable pulse width – e.g. some older GPS module have a 1us pulse and this will not be long enough. The QLG1 GPS receiver provides a 100ms (0.1s) duration pulse, though shorter pulses would also work.
- 9,600 baud serial data sending standard NMEA 0183 GPS sentences
- "TTL" voltage levels i.e. 0V "low" and 5V "high" (or at least, below 1.5V and above 3.5V)

The 1pps and Serial data signals from the GPS are connected via 1K resistors, to the "dit" and "dah" inputs to the microcontroller. The GPS is therefore wired directly in parallel with the paddle. The GPS may not be used at the same time as the paddle. This would cause the transmitter to be keyed by the 1pps and serial data signals. The 1K resistors protect the GPS outputs in case the paddles or onboard microswitch "key" inadvertently ground them.

The ATmega328P has a USART serial data peripheral. However, the pin assignments were already made, so far down the design process, at the time the GPS receiver option was included. Furthermore, the I/O pin availability was already scarce. So, the two GPS signals share the same I/O as the paddle inputs. A software-emulated USART peripheral module now reads the GPS serial data, at 9600 baud.

5.15 In Circuit Programming (ISP) interface

A 2 x 3-pin header is installed on the PCB to facilitate In Circuit Programming (ISP) of the ATmega328P microcontroller in future, if new firmware versions become available.



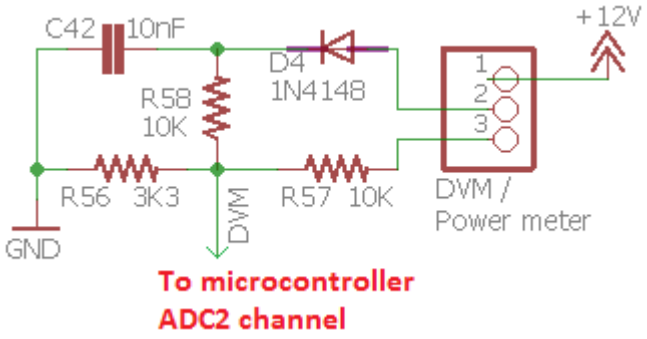
Firmware updates can be done with a simple USBISP AVR programmer available from eBay for under $2 including international shipping. The 2 x 3-pin header pinout matches the standard AVR programmer cables.

The ISP interface uses the same I/O pins as the GPS interface and the Paddle. When upgrading the firmware, be sure to disconnect the GPS (if you had one connected). And do not press any paddle key while doing the firmware update!

5.16 Test Equipment

The built-in test and alignment equipment is a really nice feature of this CW transceiver kit.

DVM and RF Power meter



The DVM and RF Power meter is implemented using the 10-bit ADC channel 2 input to the microcontroller.

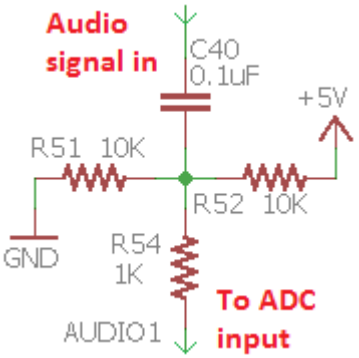
When measuring voltage, connect the voltage to be measured to pin 3 of the 3-pin DVM/RF Power connector. The voltage is dropped by the potential divider formed by R56 (3.3K) and R57 (10K). This applies a division by a factor of 4.03. Since the ADC can measure voltages up to 5V, this means the DVM function has a range of 0V to 20V maximum, and each ADC bit has a resolution of 0.02V.

When measuring RF power, connect the RF to be measured to pin 2 of the 3-pin DVM/RF Power connector. In this case D4 and C42 form a simple RF detector. The RF is rectified by D4 and smoothed by C42. R56 (3.3K) and R58 (10K) again form a potential divider that divides the rectified voltage by a factor of 4.03. The resulting range of the power meter is from 0 to 5W approximately.

For normal operation of the radio, if you wish to see a battery voltage icon on screen, then connect pin 1 to pin 3 of the 3-pin header. This connects the voltmeter input to the 12V supply of the radio.

In the unlikely event of accidentally overloading the RF power input or the DVM input, the 10K resistors R57 and R58 limit the damage to the ATmega328P processor or maybe prevent damage altogether. Perhaps. (don't feel tempted to try it intentionally).

Audio ADC

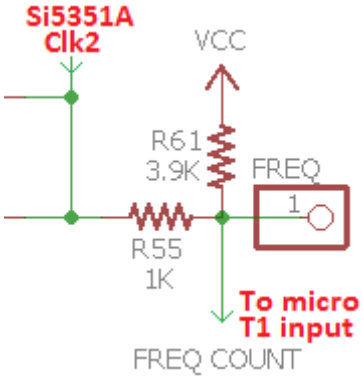


There are two audio connections from the receiver signal chain to the microcontroller. One is connected at the output of the I-Q balance adjustment potentiometer. In other words, the input to the CW filter. The second audio connection is connected after the final audio amplification gain stage. Both of these audio signal channels are fed to Analogue to Digital Converter (ADC) inputs of the microcontroller.

The circuit diagram (right) shows the circuit at AUDIO 1 (ADC channel 0) which is connected to the audio amplifier output. A duplicate circuit is used on the other channel. The purpose of the circuit is to remove the DC bias from the audio signal, and apply a new bias of 2.5V, to bias it to the middle of the ADC's input range. The 1K resistor in series with the ADC pin is intended to provide some kind of limited protection to the microcontroller in the event that the voltage falls outside the range 0-5V.

The ADCs in the ATmega328P have 10-bit resolution which translates to about 5mV. The ADC conversion result is a number in the range 0-1023, with 512 representing zero. An audio voltage of +/- 2.5V can therefore be measured. In practice, the audio signal is much less than this, which means the full ADC range is not really used. The AUDIO2 channel (connected at the CW filter input) has even less amplitude so is not used for anything except the BPF Alignment procedure, which has a very strong signal.

Frequency Counter



The frequency counter test pin input is connected directly to the microcontroller's 16-bit Timer1 input pin.

There is a 1K series resistor (R55) to connect it also to the Si5351A's Clk2 output. This is used during the optional GPS-disciplined 27MHz reference crystal frequency measurement. In this function, the Si5351A is configured to route its raw 27MHz output, divided by 4, to its Clk2 output. This passes through the 1K resistor R55, to the microcontroller. The 1K resistor provides protection to the Si5351A in the event you accidentally have something connected to the FREQ input pin, and the Si5351A is operating its Clk2 output at the same time.

Since the 3.3V peak-peak signal from the Si5351A is rather marginal for operating the Timer1 input, a 3.9K pullup resistor increases its centre point. Now "low" is 1.02V and "high" is 3.65V, which is enough to trigger the Timer1 input reliably.

The frequency counter can operate from 0 to 8MHz theoretically, assuming a clean 50% duty-cycle squarewave signal of sufficient amplitude. The 8MHz upper bound is a limitation of the AVR processor which has a synchronous timer input, and can only count to 40% of the system clock frequency (40% of 20MHz is 8MHz).

The signal to be counted must satisfy the logic thresholds of the ATmega328P, namely a "low" or "0" is less than 1.5V, and a "high" or "1" is greater than 3.5V.

Signal Generator

The signal generator mode was also discussed in the operating manual section. The signal output is simply taken from the Clk0 or Clk1 output of the Si5351A. Care should be exercised not to draw excessive load (e.g. short circuit) from these pins, which could damage the Si5351A. It will be very difficult to replace a damaged Si5351A.

Self-test of Signal Generator and Frequency Counter

Note that once the Signal Generator has been activated by scrolling to the Signal Generator menu item, and pressing the left (select) button to enable it – the Signal Generator remains active on the set frequency, until you press the right (exit) button and leave the Test Equipment menu.

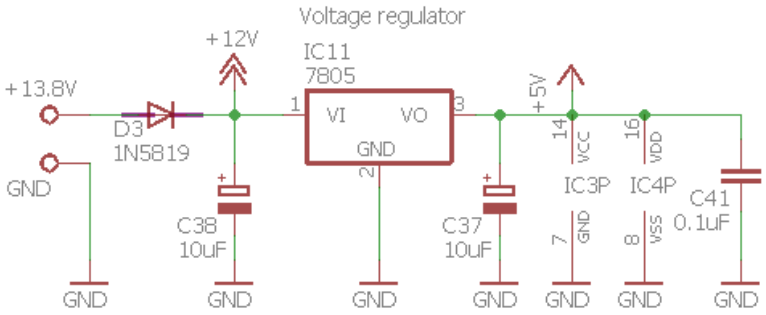
Press the left button (select) to enable the signal generator; an underline cursor appears under the digit that will be tuned by the rotary encoder. Adjust the signal generator to produce a frequency some way under 8MHz. Let's say, 6MHz. When you leave edit mode, by pressing the left (select) button until the cursor disappears off the right side of the 1's digit, OR by pressing the right button (exit), then the cursor will no longer be shown on the display. Turning the rotary encoder 1 click anticlockwise shows menu 9.5, the frequency measurement. Now if you connect a wire from the FREQ input to the CLK0 output, you will measure the signal generator's frequency. This is shown here in the photograph (right); clearly the 2kHz low reading indicates I have not calibrated the 27MHz reference value and/or the 20MHz system clock value!

In the photograph, the white wire shown looping around the rotary encoder connects the FREQ pin (just under the “M” character of the LCD, in the photograph) to the Clk0 output pin (just under the “z” character of the LCD).

This is a convenient way to get the frequency counter to verify the correct operation of the signal generator (and hence the Si5351A synthesiser). The signal generator output is available at both the Clk0 and Clk1 pins, hence you can test them both.

5.17 5V voltage regulator

5V for the microcontroller, Quadrature Sampling detector chip, LCD module and IC3 (quad NAND gate) is provided by IC11, a 7805 5V 1A voltage regulator.

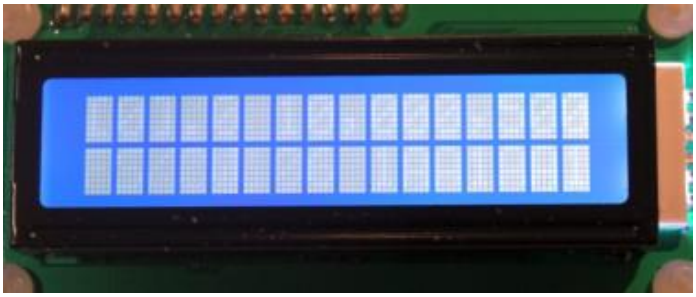


Note that the input is protected against reverse polarity by D3, a Schottky diode type 1N5819. This also drops the voltage by 0.3 to 0.4V, which has the effect of reducing the output power.

If you are brave, and confident that you will NEVER connect power to the radio with reversed polarity, you can omit this diode and fit a jumper wire over it.

6. Fault-finding

6.1 Blank LCD or blocked LCD



If your LCD screen looks like either of these, then it is a sure sign that you have not adjusted the contrast trimmer potentiometer R47.

6.2 No backlight at all

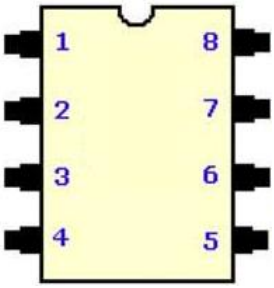
If there is no LCD backlight at all, check that you have installed R48, and also check that you have properly installed the LCD connector between the main PCB and the LCD module.

6.3 A row of blocks appears on the top row

If you see a row of blocks along the top of the LCD module, and the bottom row is empty, this means that the microcontroller has not communicated with the LCD module.

Check that your IC2 microcontroller is correctly installed in its 28-pin socket, with the correct orientation (dimple on the chip matches the dimple on the socket and the PCB silkscreen). Check that all of the pins of IC2 are correctly inserted in the socket, not bent.

6.4 DC voltage readings



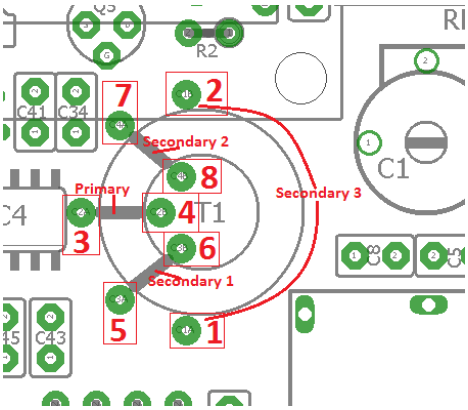
The following table lists the DC voltage read at various points around the circuit. This may aid troubleshooting. The voltage measurements were made using the in-built DVM, in menu item 9.1. These measurements were made using a 12V power supply.

Where an IC pin number is mentioned, remember that pin numbers start from the top left (just to the left of the dimple at the end of the chip) and are counted anticlockwise from there (see diagram of 8-pin IC for example, right).

Where “left”, “right”, “top” and “bottom” are mentioned, they assume the PCB is orientated in the normal way.

All measurements were made probing the PCB from the top side. In some cases, poke the wire to touch the pad of a particular capacitor or resistor.

References to the pinout of transformer T1 use the nomenclature indicated in the diagram (right).



In many cases these measurements may not exactly match your own. In particular if you use a power supply other than 12V, then voltages which are derived from the 12V supply line will be different. For example, bias voltages on op-amps which are biased to half the supply rail.

Bear in mind that in some of these measurements, the act of measurement will itself change the measurement. The “input resistance” of this DVM is only 13.3K (R56 and R57 in series, assuming high input resistance of the microcontroller pin). If you were to make these DC measurements with a high input resistance “real” DVM rather than the inbuilt DVM of this radio transceiver, these measurements would change. Again: if your measurement is in the right ballpark, do not worry if it differs from these.

When making these measurements, be very careful that whatever wire you are using to probe the circuit does not cause shorts to adjacent pins or components, which could cause damage.

I suggest avoiding directly probing the Si5351A chip pins, they are just too small: the risk of shorting adjacent pins is high. You can easily probe nearby components which are connected to the Si5351A pins, if you wish – refer to the PCB tracks diagram. Similarly, I do not recommend directly probing the FST3253 pins. Again, it is easy to probe nearby components which are connected to those pins, and reduces the risk of damaging something by causing inadvertent short circuits.

Location	Voltage	Comment
+ supply terminal	11.98	As I already mentioned: a 12V supply
Clk0 test pin	~1.70	The Clk0 pin in normal operation has a 3.3V peak-peak squarewave with 50% duty cycle. The DVM is measuring the average of that. Measuring here makes a lot of nasty noise in the audio.
Clk1 test pin	~1.70	The Clk1 pin in normal operation has a 3.3V peak-peak squarewave with 50% duty cycle. The DVM is measuring the average of that. Measuring here makes a lot of nasty noise in the audio.
Left side of C2	3.40	This is the voltage of the Si5351A supply, pins 1 & 7
Right side of D2	4.96	This is the +5V regulated supply
T1 pins 1, 2, 3 & 4	0.00	
T1 pins 5, 6, 7 & 8	2.36	
Top side of C43	2.28	C43-46 are the QSD integrating capacitors. The voltage across each one differs slightly. The following measurements show these small differences.
Top side of C44	2.44	
Top side of C45	2.42	
Top side of C46	2.30	
IC5 pin 1	2.64	IC5a output, the pre-amp I output

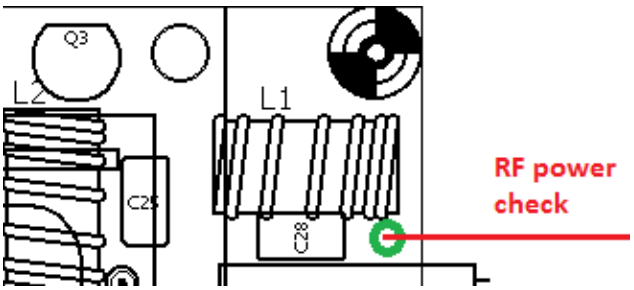
LCD pin 4	4.92	LCD RS pin
LCD pin 5	0.00	LCD RW pin
LCD pin 6	0.00	LCD E pin
LCD pin 7	1.08	LCD DB0 pin
LCD pin 8	1.08	LCD DB1 pin
LCD pin 9	1.06	LCD DB2 pin
LCD pin 10	1.04	LCD DB3 pin
LCD pin 11	0.00	LCD DB4 pin
LCD pin 12	4.94	LCD DB5 pin
LCD pin 13	4.92	LCD DB6 pin
LCD pin 14	0.00	LCD DB7 pin
LCD pin 15	4.41	LCD backlight anode
LCD pin 16 (rightmost)	0.00	LCD backlight cathode

6.5 RF Power output check

If you go into menu “9.2 RF Power”, you can check your RF power output. Your RF output should preferably be connected to a dummy load, since the RF power calculation assumes that the voltage is across a 50-ohm load.

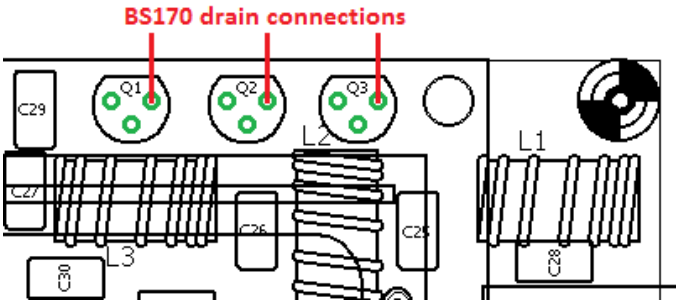


At the top right corner of the PCB, you will find a pad on the PCB where the L1 wire is soldered in. This pad is connected directly to the RF output pin of the BNC connector (see diagram). If you connect a wire from here, to pin 2 of the 3-pin DVM/RF Power header, then key-down, the display will read the power output in Watts. It is easiest to have the transceiver in Straight key mode and just press the microswitch.

Remember that the simple diode RF detector is not likely to be particularly accurate. But if you see a reading of a few watts, it will give you confidence that your transmitter is working properly.

If you do NOT see any power output on key-down, then you probably have a fault in the Power Amplifier. A common mistake, as I mentioned previously during the assembly steps, is failure to remove or burn off the enamel insulation on the enamelled copper wire wound onto the toroids.

Check the RF power wire touched to the BS170 drains first (see diagram). You can still touch the wire to these BS170 drains from the top side of the board. Key-down and check the wattage reading. At this point the indicated power will be even less reliable than across the dummy load. But at least see if it reads e watts.



If you see power output at the BS170 drains, but not at the overall transceiver RF output, then this means that the fault lies in the Low Pass Filter. Check the soldering and the enamel situation, on those toroids.

If you do not even see power output at the BS170 drains, then perhaps the L4 drain inductor in the PA has incorrectly soldered wires, that have not made an electrical connection – so check the L4 wires first and make sure the enamel is properly scraped or burnt off, to make a proper connection.

To probe other parts of the Power Amplifier circuit is less easy, because the LCD module prevents easy access. You will need to prop the PCB up vertically, and reach behind with the wire, while trying to still be able to watch the LCD screen from the front.

6.6 Audible continuous clicking noise during receive

This is not a fault of the radio, it is a consequence or limitation of the simple design. When the LCD is updated by the microcontroller, the activity on the signal lines to the LCD and in the microcontroller, causes digital noise which propagates into the sensitive radio receiver. In most cases when the display is updated, for example, when you change the frequency, this weak click is completely inaudible. In any case altering the frequency results in an inevitable audio discontinuity as the received spectrum suddenly shifts to the new LO frequency, and this more than masks any weak click from updating the display.

The continuous clicking noise during receive, sounding like the motor of a boat (perhaps), is due to the display update for the S-meter. You are likely to only notice this noise when the antenna is disconnected, or you have a dummy load connected. Ordinary band noise normally massively exceeds the weak clicking.

In some cases (depending on your power supply, antenna, grounding etc) the interference may be worse than normal. If this is the case, you can just switch off the S-meter. Remember that the S-meter indication is anyway only a rough indication, and with a little experience your own ears will do a much better job of estimating Signal level of the received station. The S-meter can be switched off in the “Show S-meter” configuration parameter in the “Other” menu.

7. Measurements

The measurements in this section were performed on assembled kits. There will always be differences from one kit to the next, due to component tolerances, adjustment differences, how you wound toroids, etc. In addition, it is often difficult to make good RF measurements. Therefore,

everything you read in this section should be interpreted as an INICATION only. Your actual results may (and probably will) differ. The following information just gives a guide of very roughly, what you might expect to see.

7.1 Equipment

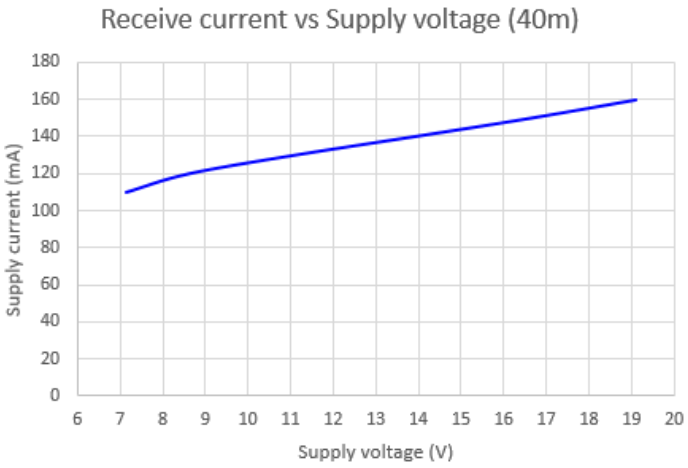
For reference, and for the sake full disclosure, the following equipment was used in making these measurements:

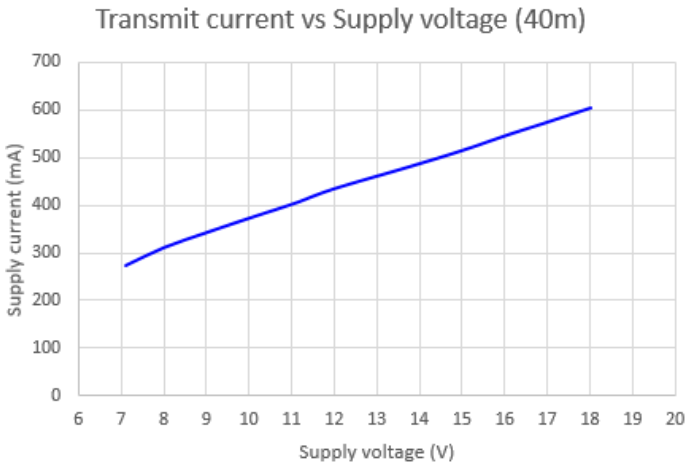
- OWON XS3102A 12-bit 100MHz Digital Storage Oscilloscope
- ADVANTEST R3361C 2.6GHz Spectrum Analyser with 50-ohm tracking generator
- QRP Labs 50-ohm Dummy Load kit http://qrp-labs.com/dummy
- XONAR U5 24-bit external USB sound card
- Argo and Spectran audio analysis software from http://weaksignals.com
- QRP Labs Ultimate3S for test signal generation http://qrp-labs.com/ultimate3/u3s
- Simple 14.000MHz battery-powered crystal oscillator signal generator
- Two generic yellow DVMs
- 12V fixed power supply, and variable voltage bench supply

7.2 Transceiver current consumption

The current consumption of your radio may be an important consideration if you intend portable battery-powered operation. Current consumption depends on supply voltage.

These measurements were carried out on a 40m band version of the kit. They will not differ much for other bands. At 13.8V supply for example, current consumption is about 140mA on receive, and almost 500mA on transmit.





At supply voltages above 13.8V, check the temperature of the 7805 voltage regulator, which may need a heatsink as it dissipates more heat at higher supply voltages.

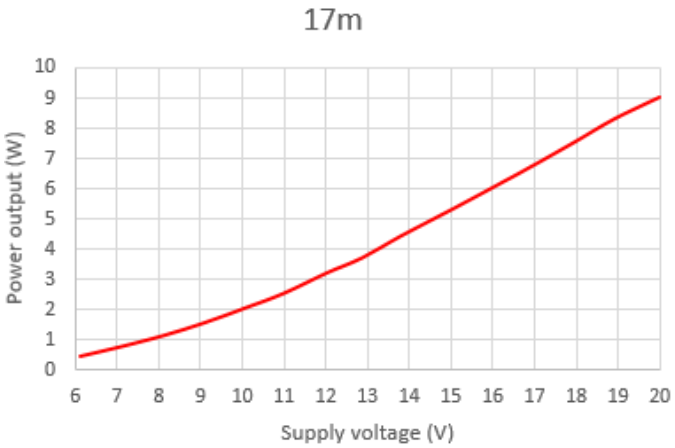
7.3 Transmitter power output

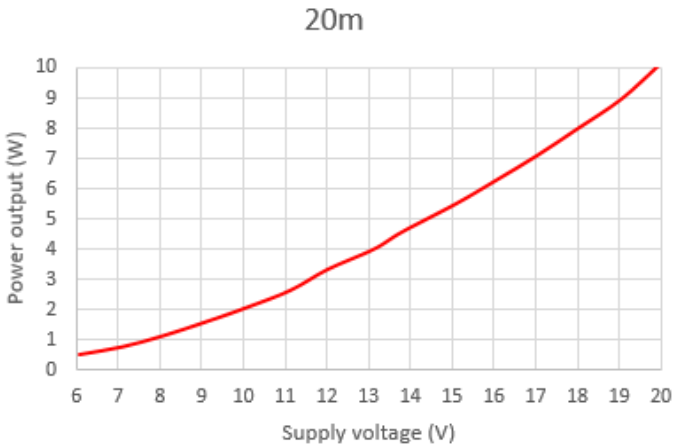
The transmitter RF power output varies depending on the power supply voltage. It is also dependent on band. Your results may vary depending on your Low Pass Filter inductor construction! If the cut-off frequency becomes too low, then you can start to get attenuation at the operating frequency. In this case you can remove a turn or two from each toroid.

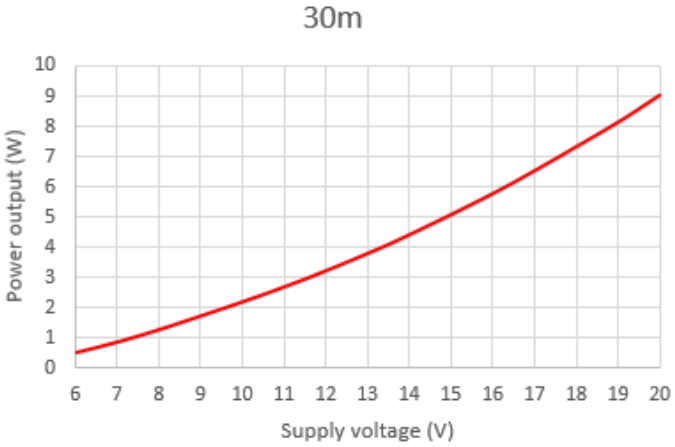
The following charts show the power measurement using the oscilloscope to measure the peak-peak amplitude across the 50-ohm dummy load.

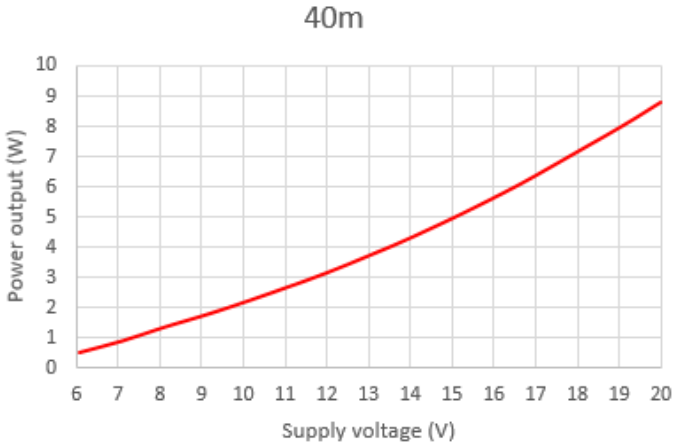
Operation at output power levels above 5W is NOT recommended, as it will put too much strain on the BS170 output transistors which may result in failure. For this reason, limiting the supply voltage to not more than 15 or 16V is recommended.

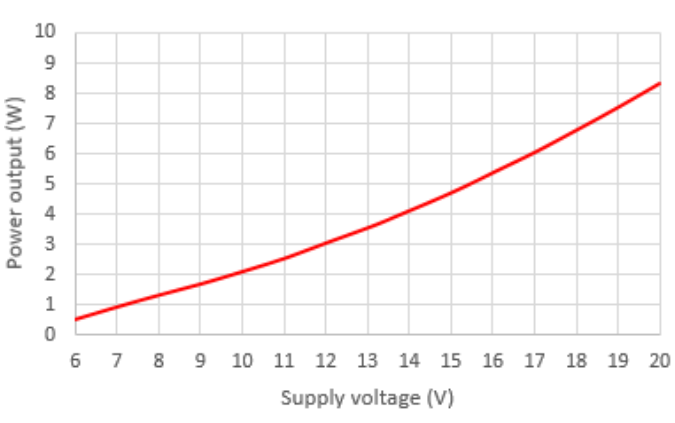
Note that these measurements do not take into account the D3 1N5819 reverse polarity protection diode voltage drop (approximately 0.3 or 0.4V). In other words, the measurements were done in a transceiver with D3 bypassed by a wire link.

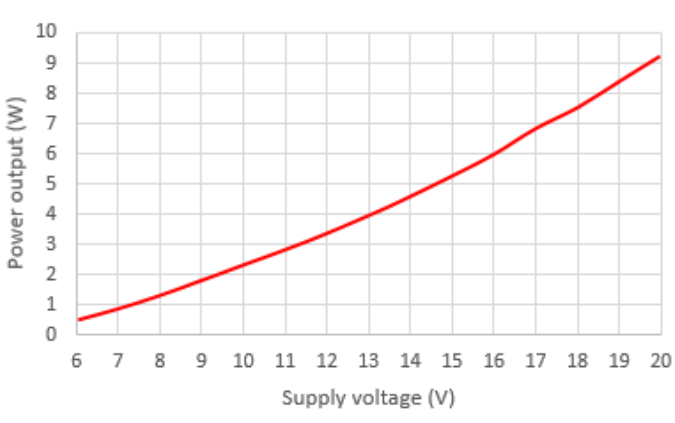








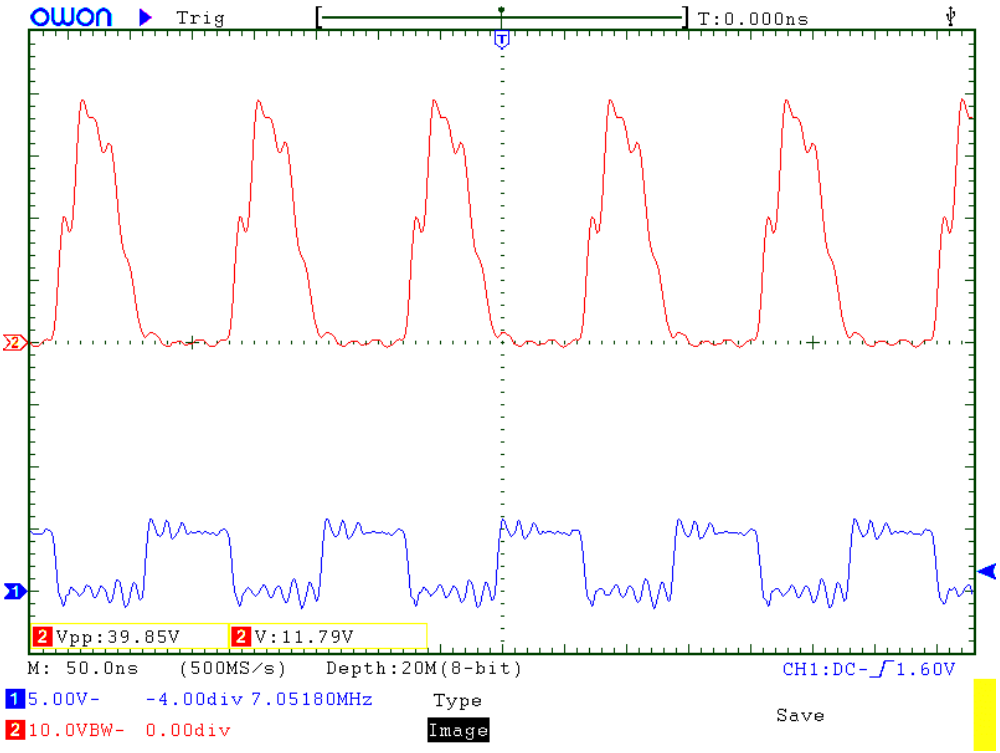




7.4 Class-E Power Amplifier drain waveform

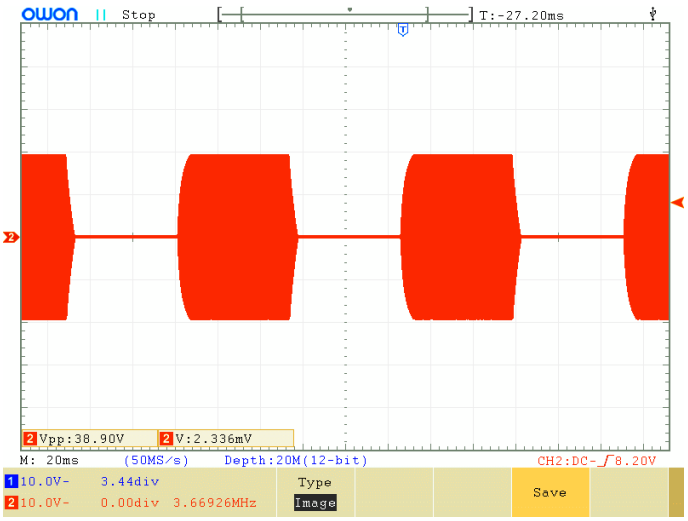
This oscilloscope chart shows the waveform at the BS170 drains (top, RED colour trace) and the input drive waveform, a 5V peak-peak squarewave (bottom, BLUE trace). The 40m band is shown.

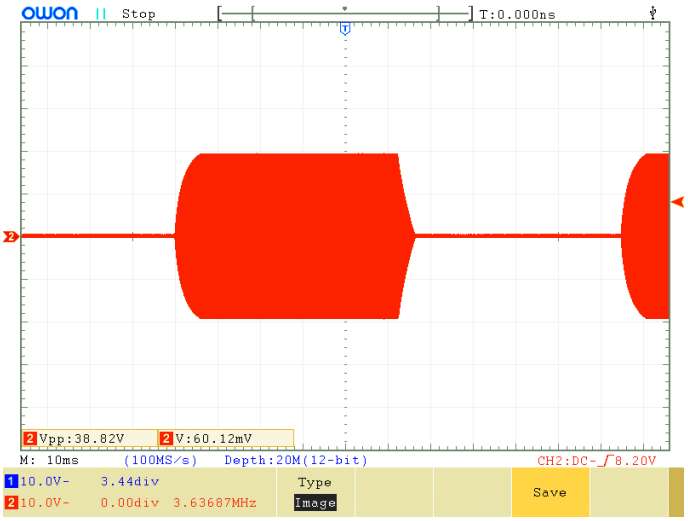
Upon ignoring the “ringing” artefacts due to poor ‘scope probes etc., the waveforms are correct for Class-E operation.



7.5 RF envelope key-shaping

The following oscilloscope images show the RF envelope when keyed with a continuous 24 words per minute (50ms duration) string of dits. The simple key-shaping circuit described earlier results in rise/fall times of around 5ms and significantly attenuates key-clicks.





7.6 Low Pass transmitter harmonic output filter characteristics

The Low Pass Filter response was not measured. The Low Pass Filter is the same as the QRP Labs Low Pass Filter kit module http://qrp-labs.com/lpfkit . Measurements of the Ultimate3S kit http://qrp-labs.com/ultimate3/u3s using these filters is on this page http://www.qrp-labs.com/ultimate3/u3info/u3spec.html

7.7 Band Pass receiver input filter characteristics

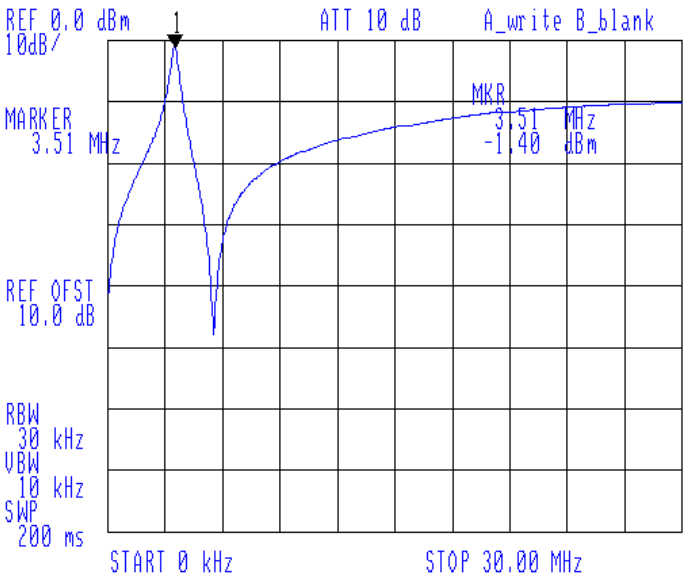
The following charts show measurements of the simple band pass receiver input filter implemented using transformer T1. For each band, one image shows the close-in response, the other shows the response across 0 to 30MHz.

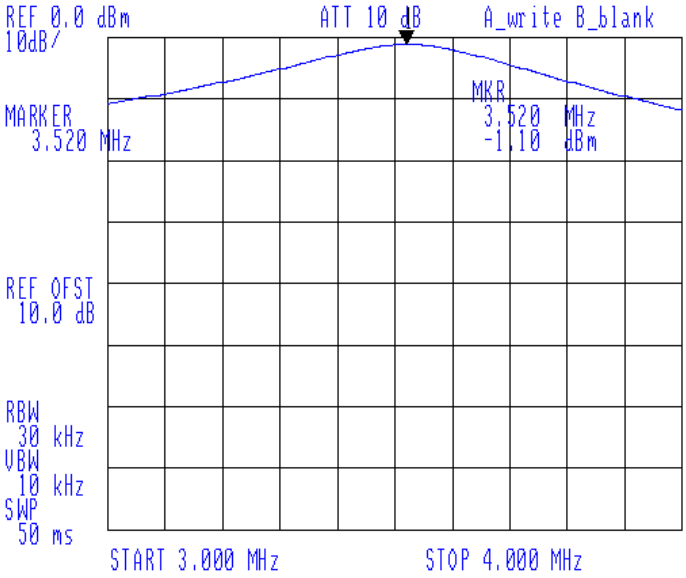
Note that in the circuit, the Band Pass filter sits behind the Low Pass filter. Therefore, the low pass filter response is ADDED to the band pass filter response. These charts show a relatively poor attenuation above the passband – but this is not a problem because in this region the Low Pass Filter provides high attenuation.

For each band, the 3dB bandwidth was measured. The tuning range available was also measured (from having the C1 trimmer capacitor plates fully meshed, to having them fully un-meshed). Also shown is the attenuation at the centre frequency.

80m band

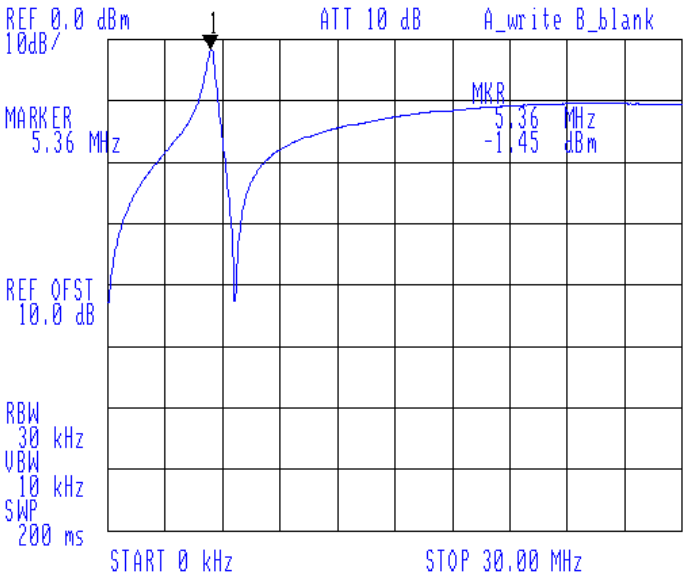
3dB bandwidth: 343kHz
Insertion loss: 1.10dB at 3.520MHz centre
Tuning range: 3.320MHz to 4.03MHz

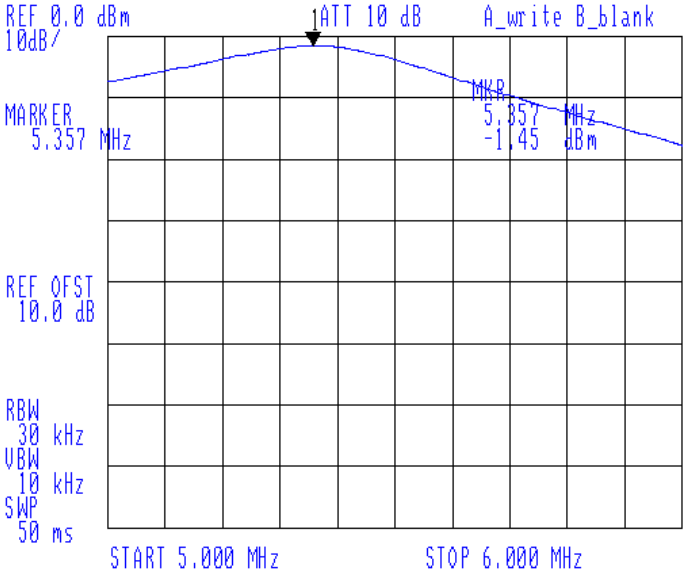




60m band

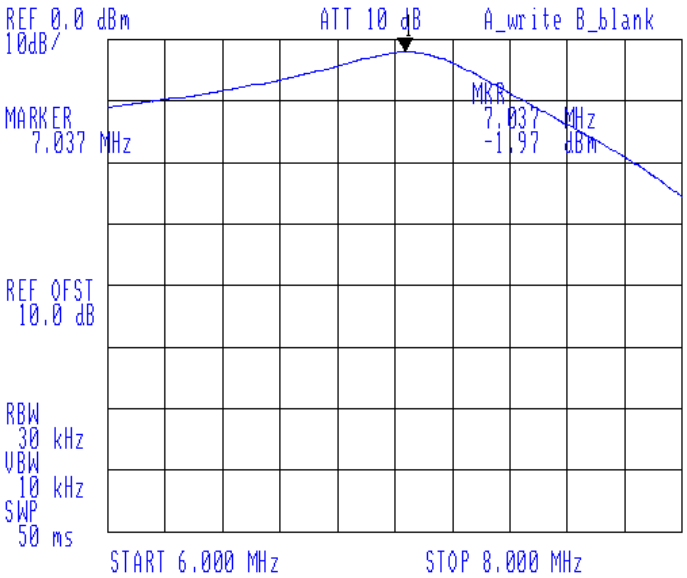
3dB bandwidth: 367kHz
Insertion loss: 1.45dB at 5.357MHz centre
Tuning range: 4.63MHz to 5.91MHz

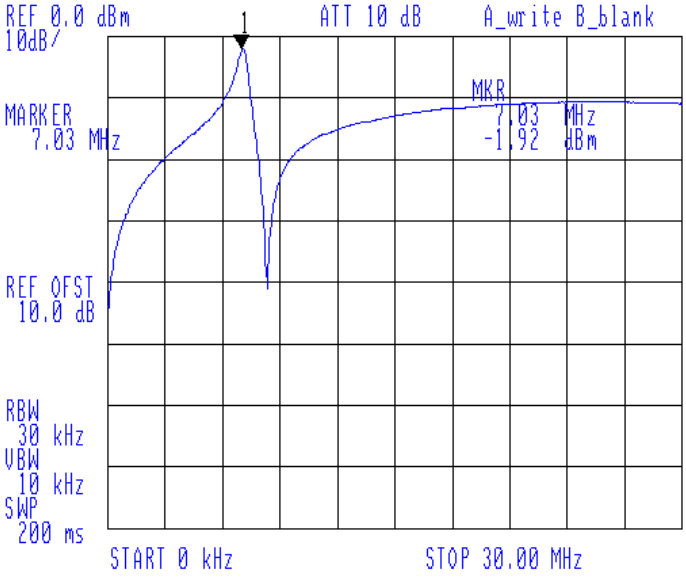




40m band

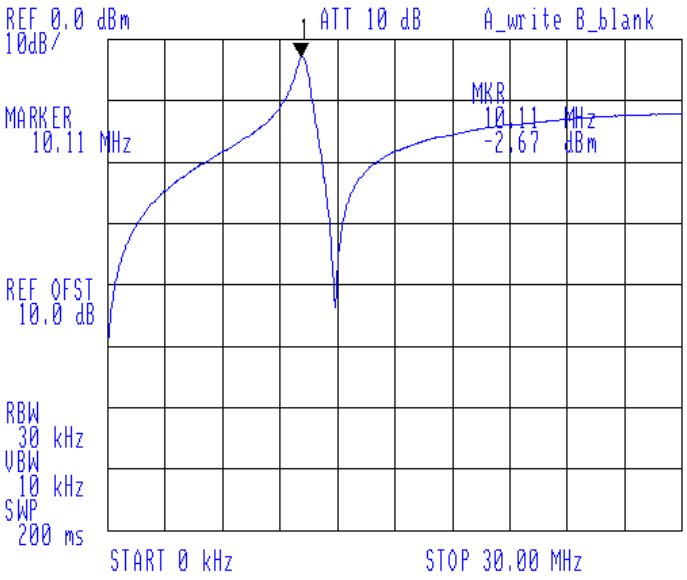
3dB bandwidth: 514kHz
Insertion loss: 1.97dB at 7.020MHz centre
Tuning range: 6.04MHz to 8.36MHz

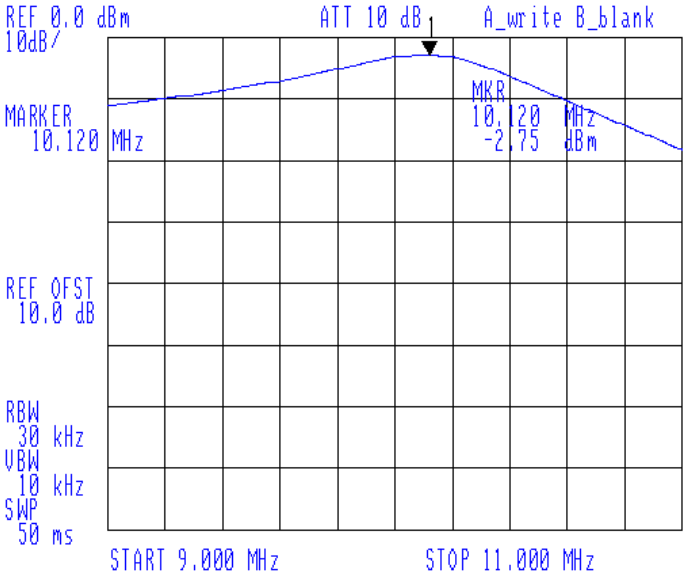




30m band

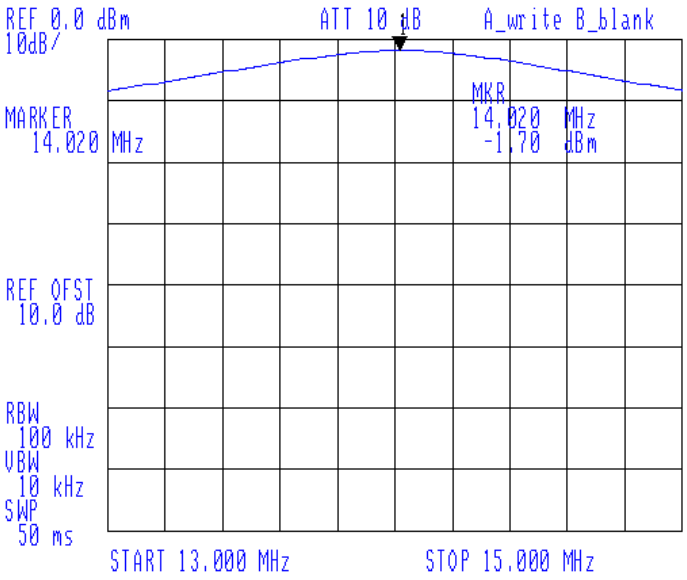
3dB bandwidth: 645kHz
Insertion loss: 2.67dB at 10.120MHz centre
Tuning range: 7.93MHz to 12.47MHz

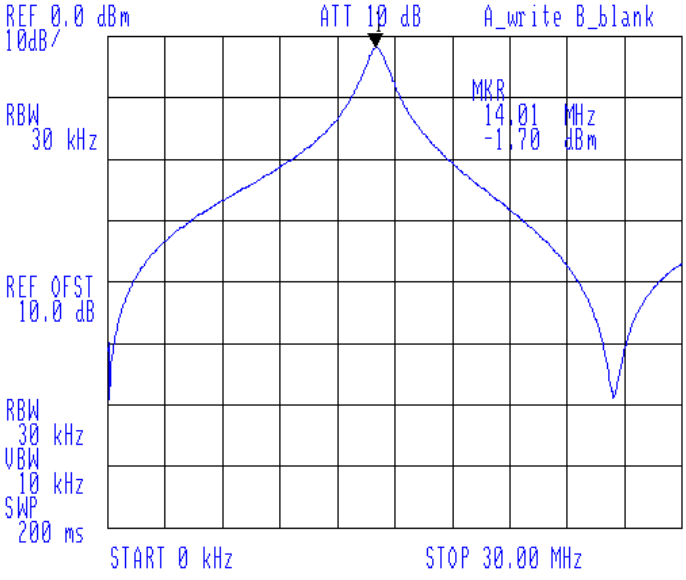




20m band

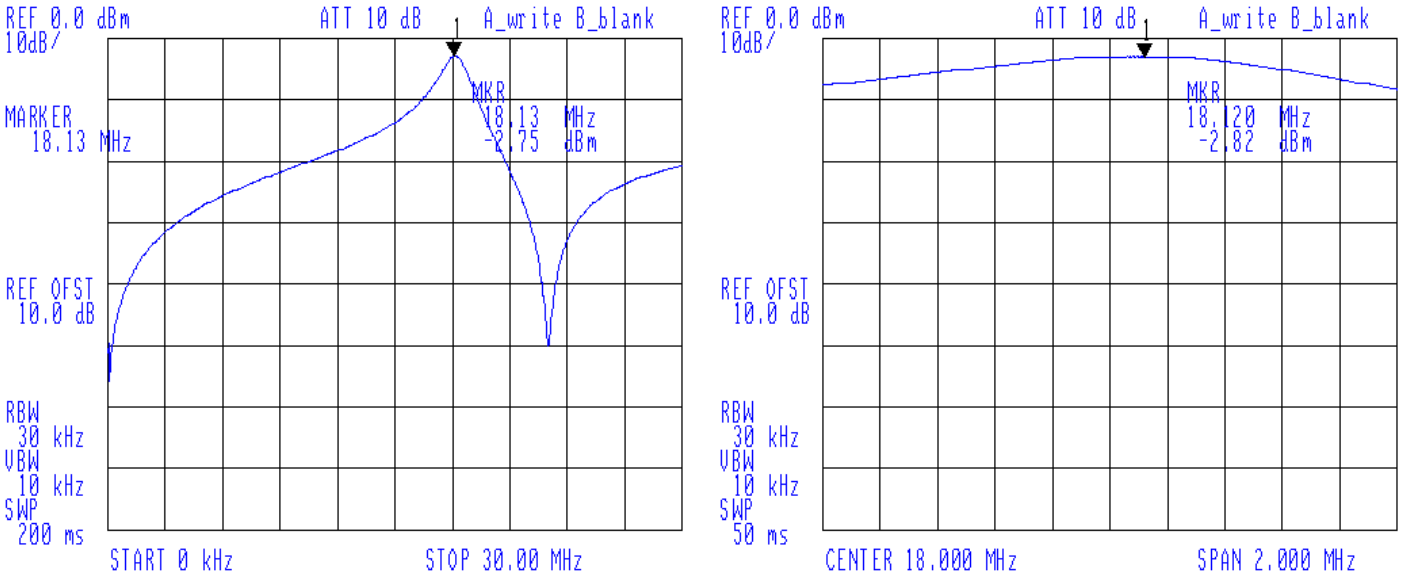
3dB bandwidth: 1,083kHz
Insertion loss: 1.30dB at 14.020MHz centre
Tuning range: 9.69MHz to 22.54MHz





17m band

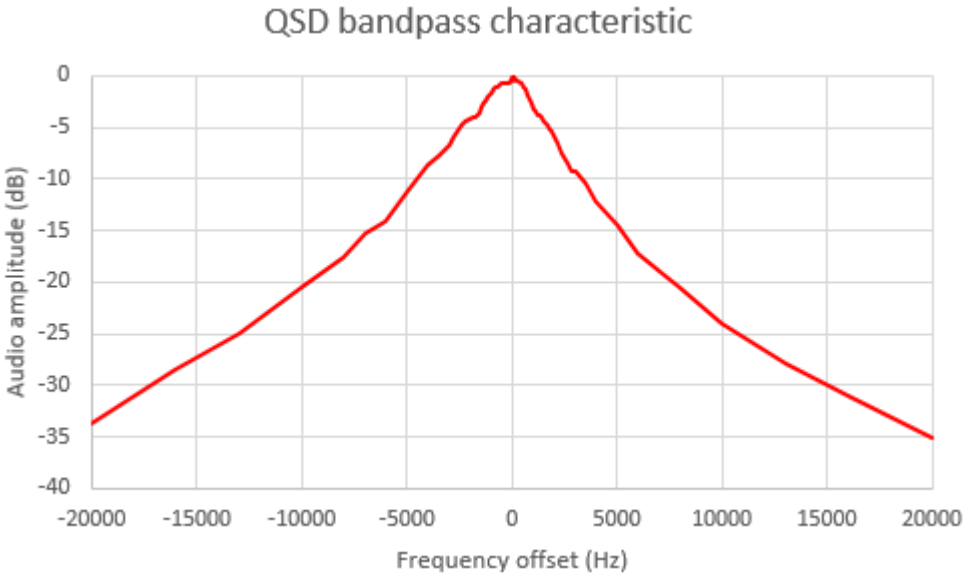
3dB bandwidth: 1,352kHz
Insertion loss: 2.77dB at 18.120MHz centre
Tuning range: 12.64MHz to 35.0MHz



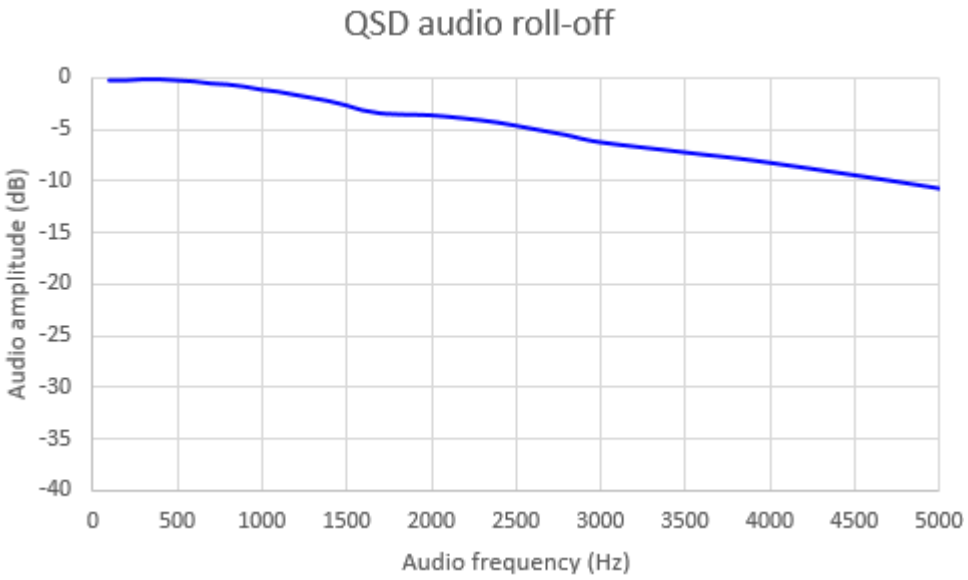
7.8 Quadrature Sampling Detector bandwidth

The following chart shows the attenuation naturally provided by the Quadrature Sampling Detector from -20kHz to +20kHz from the Local Oscillator frequency. The narrow characteristic of this circuit is an advantage because it effectively adds an additional narrow RF bandpass filter to the receiver, preventing strong nearby signals from reaching the audio amplifier stages. This improves intermodulation performance.

The circuit parameters are optimised for CW operation in this transceiver. A constructor wishing to use the I-Q outputs from IC5 to feed a computer SDR, would wish to flatten this response. To do this, reduce the values of the four 470nF capacitors C43 to C46.

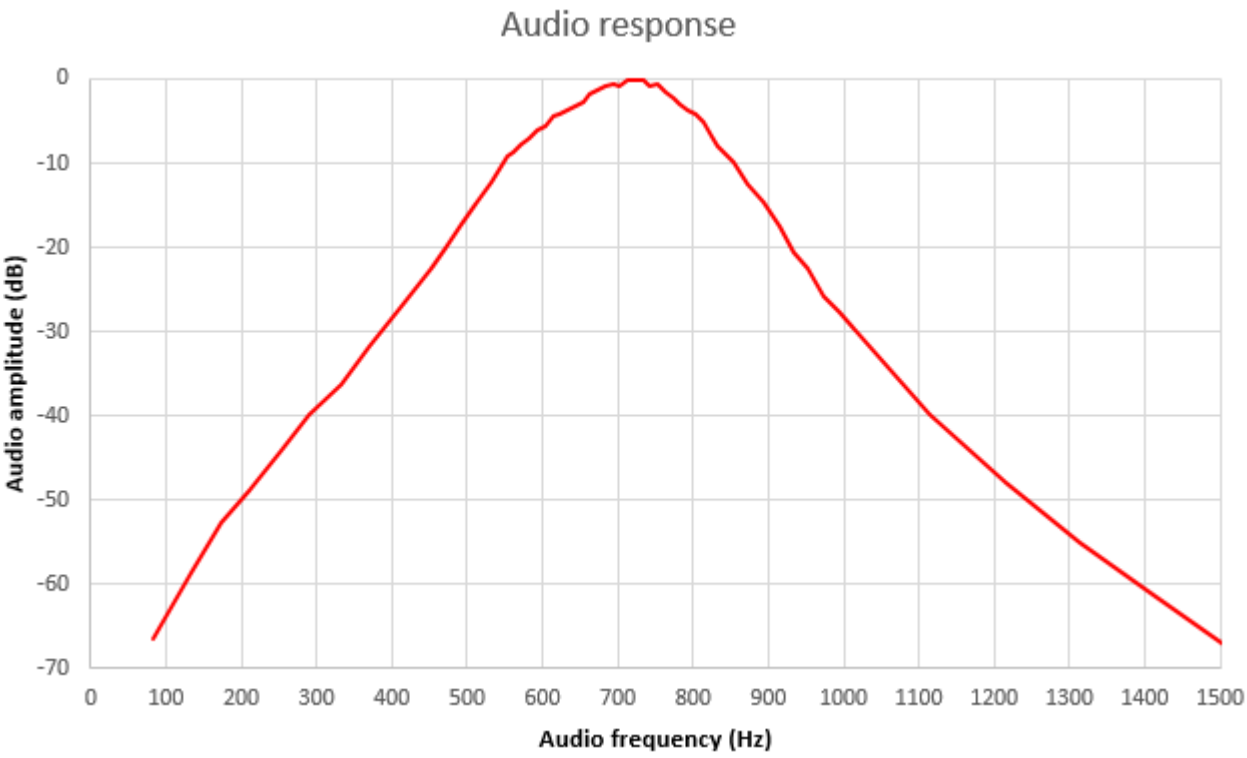


The following chart shows the Quadrature Sampling Detector roll-off over the narrower range 0 to 5kHz. You can see that at the CW operating frequency 700Hz, the attenuation is insignificant; the roll-off of the QSD does not significantly improve the selectivity of the CW filter, but it does improve the intermodulation characteristics of the receiver.



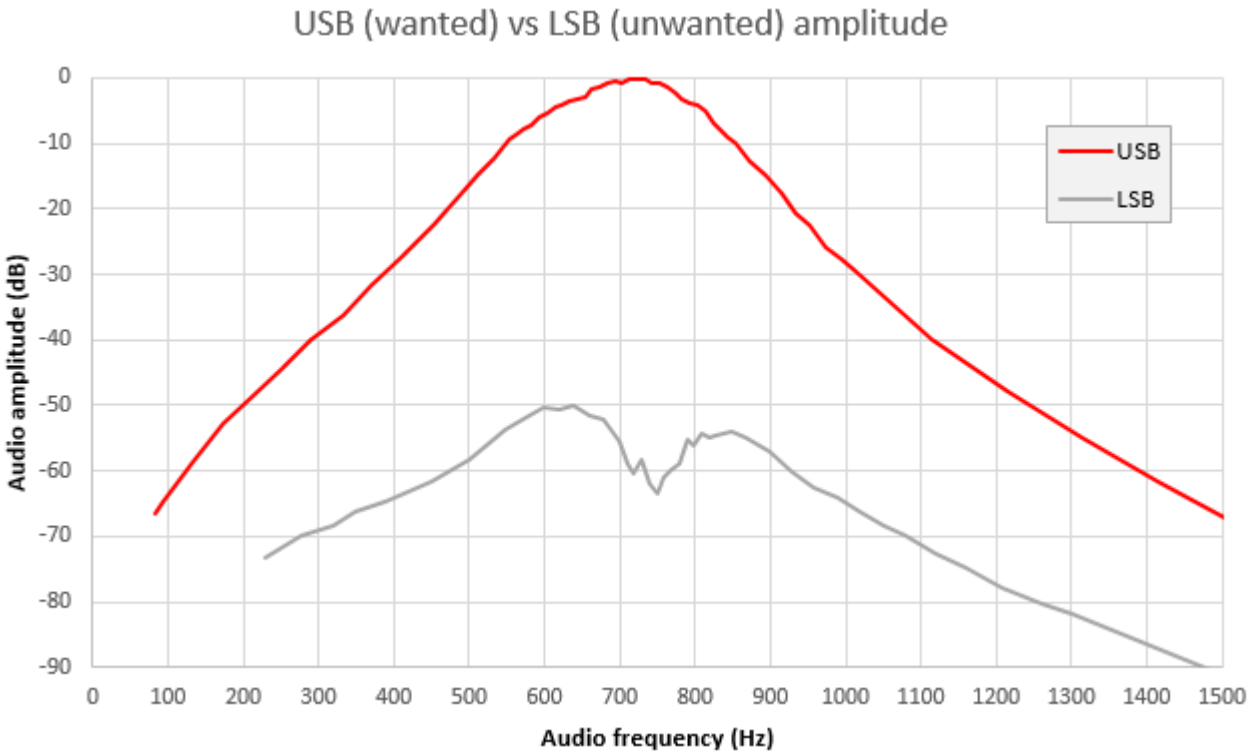
7.9 CW Filter response

This chart shows the measured response of the CW filter (combined with the other filtering in the receiver chain). It was measured by tuning the receiver across a test signal. Note that the centre frequency, a little over 700Hz, could be altered by changing some component values.

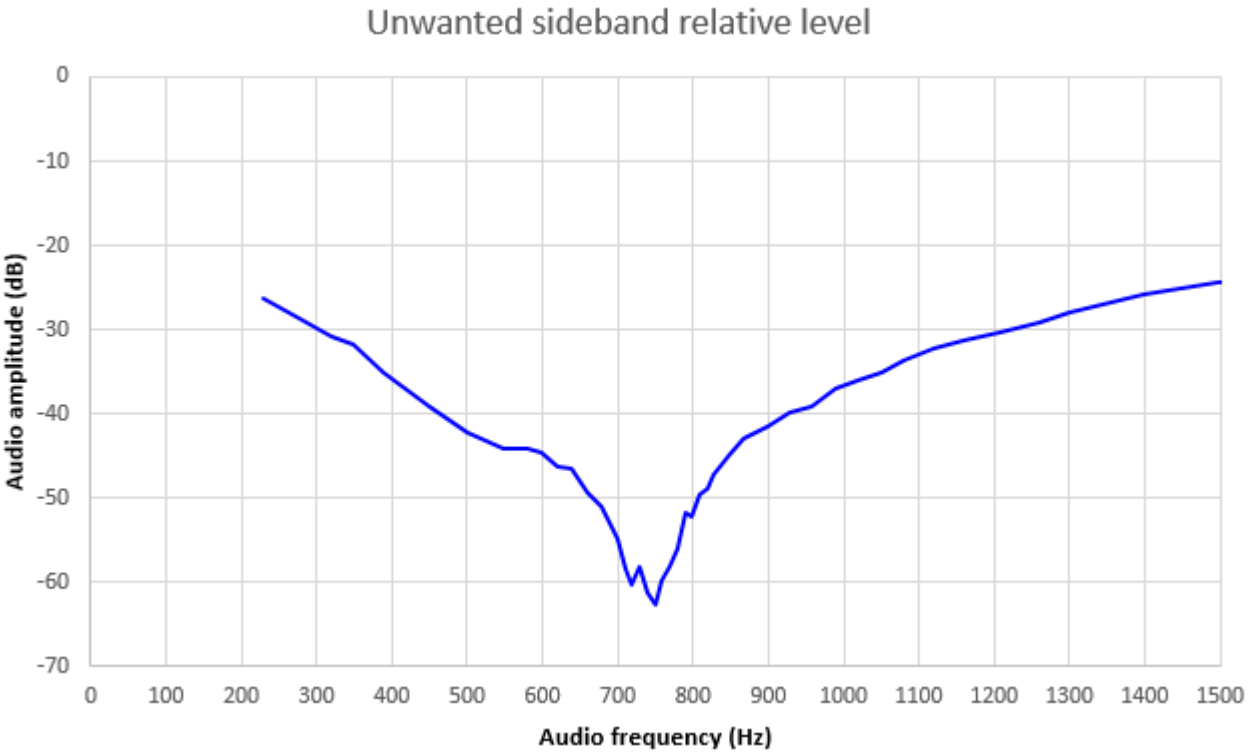


7.10 Unwanted sideband rejection

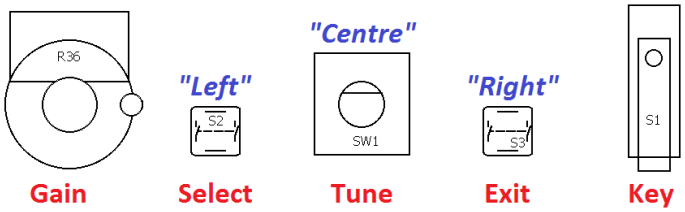
The following chart shows the measured level of the Upper Sideband signal (USB) and the unwanted Lower Sideband signal (LSB) when tuning the receiver through a strong test signal. The curves depend very heavily on the I-Q balance and audio phase shift adjustments, and these curves are from one measured prototype.



Subtraction of these two curves results in the unwanted sideband level as shown in the following chart. Normally anything above 40dB rejection is considered good; above 50dB is excellent. With the built-in adjustment features of this kit it is relatively easy to achieve really excellent unwanted sideband rejection.



8. Operation reference "cheat sheet"



Main controls functions:

Left single press: Keyer speed adjust, then left again to select, or right to cancel. **Left double press**: RIT adjust, then left again to select, or right to cancel **Left long press**: Enter the configuration menu (see below)	**Encoder turn**: tuning, menu selection, editing, etc **Encoder press**: change tune rate 1kHz->500Hz->100Hz->10Hz **Encoder dbl or long press**: choose stored message. Then Left to send repeatedly, Centre to send once, or Right to cancel	**Right single press**: change VFO mode: A, B, Split **Right Double press**: Select frequency preset. Then press Left (save VFO to preset), Right (load preset to VFO) or Centre (cancel) **Right long press**: swap VFO A and B frequencies

Configuration menu items:

1 Preset

Preset 1 to Preset 16: Enter frequency presets.

2 Messages

2.1 Message 1 to Message 12: Stored messages. First four are 100 characters, rest are 50 characters.
2.13 Interval: gap between message transmissions, in seconds
2.14 Repeats: number of message repeats, 1 to 99 or infinite

3 VFO

3.1 VFO mode: A, B or Split
3.2 VFO A: startup frequency
3.3 VFO B: startup frequency
3.4 Tune rate: startup rate, 1kHz, 500Hz, 100Hz or 10Hz
3.5 RIT: Receive incremental tuning
3.6 RIT rate: 1kHz to 1Hz
3.7 CW mode: CW or CW-R (reverse)
3.8 CW offset: default offset (700Hz)
3.9 Band: configure once at start-up

4 Keyer

4.1 Keyer mode: Straight, Iambic A/B, Ultimatic
4.2 Keyer speed: in words per minute
4.3 Keyer swap: swap paddle inputs
4.4 Keyer weight: alter dit:space ratio
4.5 Auto space: enable keyer autospacing (default OFF)
4.6 QSK: full or semi break in
4.7 Practice: enable practice mode, keys but no RF output
4.8 Sidetone frq: normally set to same as CW offset (700Hz)
4.9 Sidetone vol: volume, 0 to 99

5 Decoder

5.1 Noise blanker: period in ms
5.2 Speed Avg: for speed detection
5.3 Ampl. Avg: for ampl. detection
5.4 Enable Rx: enable Rx decoder
5.5 Enable Tx: enable Tx decoder
5.6 Enable Edit: enable CW decoding during menu editing (useful!)

6 Beacon

6.1 Beacon: On/Off enable beacon operation
6.2 Mode: CW or WSPR
6.3 Frequency: beacon frequency
6.4 Frame: frame duration in minutes
6.5 Start: minutes past the hour to start
6.6 WSPR call: Callsign to encode in WSPR message
6.7 WSPR locator 4-character Maidenhead square
6.8 WSPR power dBm power level to encode in WSPR message
6.9 Set time: set real time clock

7 Other

7.1 Dbl click: dbl click delay time in milliseconds (300)
7.2 Batt. show: enable battery icon on the display top right
7.3 Batt. Full: set millivolts for a "full" battery icon indication
7.4 Batt. set millivolts for each battery bar step level in the icon display
7.5 Cursor style: underline/flashing
7.6 Show S-meter: enable S-meter display on the screen
7.7 S-meter step: set value of each S-meter bar (in amplitude units)
7.8 Factory rst.: Factory reset, if set to value 17 – use with caution

8 Alignment

8.1 Alignment freq: frequency for BPF alignment
8.2 I-Q balance freq: audio frequency for I-Q balance adjustment (700Hz)
8.3 Phase adj Lo freq: audio freq for low audio phase adj (600Hz)
8.4 Phase adj Hi freq: audio freq for high audio phase adj (800Hz)
8.5 Ref. frq.: 27MHz synth reference frequency used for synthesiser
8.6 System frq.: 20MHz system clock frequency used for system timing
8.7 Peak BPF: do the actual BPF peaking alignment
8.8 I-Q bal.: do the I-Q balance adjustment
8.9 Phase Lo: do low audio phase adjustment
8.10 Phase Hi: do high audio phase adjustment
8.11 Cal ref. osc: do GPS calibration of 27MHz osc if GPS is connected
8.12 Cal sys. osc: do GPS calibration of 20MHz osc if GPS is connected
8.13 GPS data: show GPS satellite data if GPS is connected

9 Test equipment

9.1 Voltage: measure voltage
9.2 RF Power: measure RF power
9.3 Audio Ch.0: measure audio channel 0 amplitude
9.4 Audio Ch.1: measure audio channel 1 amplitude
9.5 Frequency: measure frequency
9.6 Signal gen.: enable and adjust signal generator output

Save settings!: save current VFO etc settings to be the default on power up; press left (select) to save, right to cancel

9. Resources

- For updates relating to this kit please visit the QRP Labs CW transceiver kit page http://qrp-labs.com/qcx
- For any questions regarding the assembly and operation of this kit please join the QRP Labs group, see http://qrp-labs.com/group for details

10. Document Revision History

1.00	02-Aug-2017	Initial revision for YOTA 2017
1.01	04-Aug-2017	Published draft version
1.02	18-Aug-2017	First official general release version
1.03	19-Aug-2017	Fixed some typos
1.04	21-Aug-2017	Corrected display description in section 4.2
1.05	31-Aug-2017	Added capacitor labels and resistor colour codes to parts list; added T1 diagram by Ed WA4MZS; minor corrections
1.06	25-Sep-2017	Added instruction to insert short end of the pin headers into PCB Added C47 and other minor corrections to parts list 6.4 IC pin count is anticlockwise (not clockwise) 6.4 table row 9, should be C43-47 (not 33-47) 3.17 The 1N4148 diode is at the board top left (not right) 5.14 GPS connector is at board right (not left) 4.2 Corrected description: top row is Rx VFO, bottom is Tx VFO 3.41 Corrected photo of 470uF which was reversed polarity
1.07	17-Oct-2017	Changed Q6 transistor to MPS751 (was MPS2907 in first kit batch) Corrected typo on p83 para 3 “in the event that” 3.3K R44 was mistakenly called R34 on parts list
1.08	23-Oct-2017	Swapped R19 and R25 in parts list and sections 3.22, 3.23 to match error on silkscreen (silkscreen prints for R19 and R25 were swapped). Note in section 3.41 that C47 can be mounted vertically above SN 500.

Abstract

Two-way communications using 3 to 30 MHz, high-frequency (HF) radio, also known as shortwave radio, provides worldwide coverage with no infrastructure required between stations. Amateur or "Ham" radio operators apply this advantage to long distance communications and to provide disaster relief communications. Optimum frequencies for long distance propagation are time-of-day variant necessitating an operating frequency range of 3 to 30 MHz. HF half wave dipole antenna length varies from 15 to 150 ft over this range. Fixed-length antenna impedance varies with frequency due to physical dimension dependent capacitance and inductance. Maximum transmitter to antenna power transfer occurs when the transmission line and antenna impedances are matched to the standard 50 Ω radio impedance. For transmitter to antenna impedance matching, antenna length can be adjusted depending on frequency. Alternately, an antenna tuner utilizing a variable inductance and capacitance matching network can compensate for the frequency dependent impedance of a fixed-length antenna. A dipole antenna designed for one frequency can function over a broader frequency range with a manually or automatically adjusted antenna tuner.

The project objective is to develop a microcontroller-based automatic tuner for a fixed-length dipole antenna. In high frequency transmission lines, an antenna impedance mismatch causes power reflection back to the transmitter. This corresponds to a greater than unity voltage standing wave ratio (VSWR), the ratio of maximum to minimum transmission line voltage amplitude. A directional wattmeter provides forward and reflected power values to an Atmel ATmega32 microcontroller, which calculates VSWR and adjusts a capacitor - inductor matching network using stepper motors to reduce VSWR to less than 1.5:1 (4% reflected power relative to incident). The antenna tuner system can match loads of up to 26:1 initial VSWR within a frequency range of 3.5 MHz to 30 MHz. The system was tested using a 100 W transceiver connected to a 90 ft, 450 Ω balanced transmission line and a 120 ft dipole antenna 30 ft above ground. Commercial antenna tuners have VSWR matching capabilities from 3:1 to 100:1. [1] [2] [3]

Chapter 1. Introduction

An antenna tuner, or impedance matching system (IMS), allows use of a fixed-length antenna on a range of frequencies wider than otherwise possible. Figure 1 shows a common setup for an antenna tuner. A fixed length wire dipole is usually mounted above ground using masts. The mounting height is at least one eight wavelength above ground for the lowest operating frequency. One eighth wavelength for 3.5 MHz is approximately 30 ft. If the antenna is closer to the ground, the feedpoint impedance approaches 0 Ω and the radiation pattern is directed upward instead of at the horizon, which is more desirable for long distance communication [4]. The dipole length is typically a half wavelength at the minimum frequency of the desired operating range. For example, if the minimum frequency is 3.5 MHz, the length is:

$$\left(\frac{1}{2}\right)\left(\frac{c}{f}\right) = \left(\frac{1}{2}\right)\frac{\left[3x10^8\,\frac{m}{s}\right]}{(3.5x10^6\ Hz)} = 43\ m\ or\ 140\ ft. \qquad (1)$$

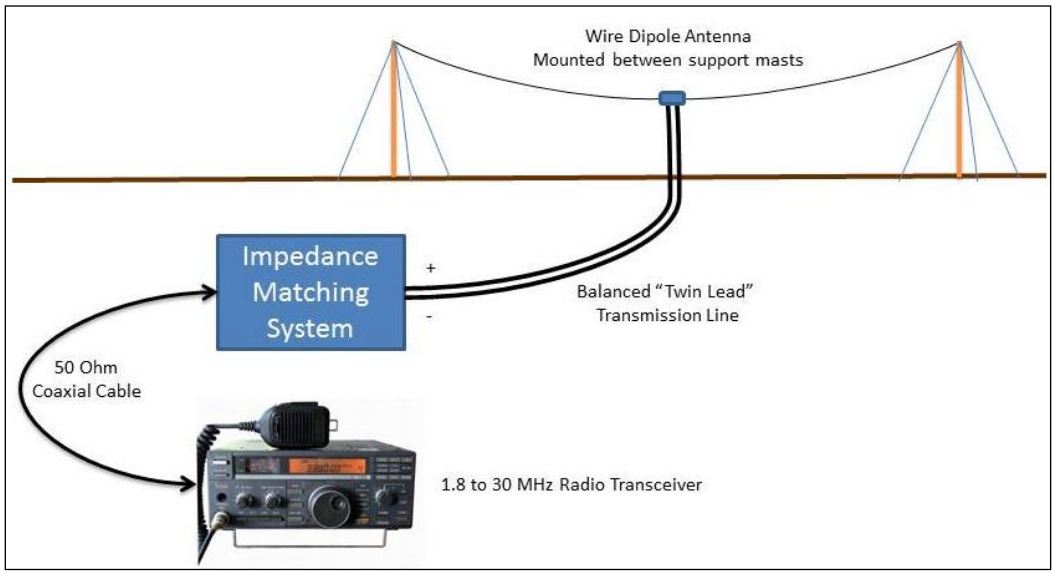

Figure 1 - Typical Impedance Matching System (IMS) Setup [5]

A typical IMS is shown in Figure 1. At power on, the IMS initializes in standby mode and measures and displays forward and reflected RF power. It calculates SWR if the RF input power is greater than 3 W. The power measurement range is 10 mW to 200 W. With the radio transceiver in receive mode, the RF power is less than 10 mW, therefore SWR calculation is not possible. Impedance matching is also important to maximize received signal strength. The user must transmit into the IMS and press the "Tune" button to initiate automatic impedance matching. The "Tune" button allows operator discretion for tuning initiation, although the IMS software could be modified to initiate tuning automatically if the VSWR exceeds 1.5:1 while

transmitting. During automatic impedance matching, the IMS calculates VSWR and actuates stepper motors to alternately adjust a variable capacitor and a variable inductor to reduce VSWR to less than 1.5:1. The IMS then returns to standby mode.

$$SWR = \frac{1 + \sqrt{\frac{P_R}{P_F}}}{1 - \sqrt{\frac{P_R}{P_F}}} \quad (2)$$

From equation (2), a VSWR of 1.5:1 corresponds to 4% reflected power. Reducing VSWR to less than 1.5:1 achieves an acceptable impedance match based on the manufacturer requirements of the transceiver used for IMS testing [6]. When transmit frequency is adjusted, an impedance mismatch will again exist requiring the operator to initiate another automatic tuning cycle to reduce VSWR.

Chapter 2. Background

Two-way communications using 3 MHz to 30 MHz, high-frequency (HF) radio, also known as shortwave radio, offers worldwide coverage with no required infrastructure between stations, making it useful for emergency communications. Worldwide range is possible due to HF radio wave refraction in the ionosphere known as skywave propagation. The ionosphere is the upper layer of Earth's atmosphere where solar radiation separates electrons from (ionizes) gas molecules. This ionized gas, known as plasma, is electrically conductive, causing incident radio waves to refract (bend) back to Earth. Earth's surface also reflects radio waves back to the ionosphere. Surface reflection and ionosphere refraction can occur multiple times along a radio signal path allowing the signal to propagate worldwide. The optimum frequency for long distance skywave propagation changes with time of day due to the sun's influence on the ionosphere. For transmitter to antenna impedance matching, antenna length can be adjusted depending on frequency. Half-wave dipole antenna length for HF radio varies from 15 ft to 150 ft.

A 140 ft dipole antenna normally resonates at 3.5 MHz. At the resonance frequency, inductive and capacitive reactances cancel. Away from resonance, the impedance changes and power reflections caused by impedance mismatch increase. An antenna tuner can render the antenna resonant to the transmitter and eliminate reflected power by providing compensation for the impedance mismatch. Matching is possible below the resonant frequency, but the voltage can exceed the dielectric strength of the transmission line or antenna tuner components. Table 1 shows possible voltages for a 100 ft "flat-top" antenna [5].

Notes

1) Antenna is a 100 ft long, 50 ft high, center-fed dipole over average ground, using coaxial (RG-213) or open-wire transmission lines. Each transmission line is 100 ft long.
2) Antenna impedance computed using *EZNEC-3* computer program using 499 segments and with the Real Ground model.
3) Note the extremely reactive impedance levels at many frequencies, but especially at 1.8 MHz. If this antenna is fed directly with RG-213 coax, the losses are unacceptably large on 160 meters, and undesirably high on most other bands also.
4) The RF voltage at 1.8 MHz for high-power operation with open-wire line is extremely high also, and would probably result in arcing either on the line itself, or more likely in the antenna tuner.

Table 1 - Loss Comparison of 450 Ω Balanced Line versus 50 Ω Coaxial Cable [5] Table 20.1. Used with permission. Copyright ARRL.

Voltage amplitude increases with reflection coefficient magnitude, |Γ|, between the antenna and transmission line and therefore increased voltage standing wave ratio (VSWR). Superposition of forward and reflected waves along the transmission line produces standing waves resulting in maximum and minimum voltage amplitude locations. VSWR is the ratio of the maximum to minimum transmission line voltage amplitude. ISWR is the corresponding ratio for current; its value is equivalent to VSWR. VSWR and ISWR are collectively referred to as SWR since they are equivalent. Equations (3) and (4) define Γ and SWR, respectively. [6]

$$\Gamma = \frac{Z_{Load} - Z_o}{Z_{Load} + Z_o} \qquad (3)$$

where Z_{Load} is the complex antenna (load) impedance and Z_o is the transmission line characteristic impedance. Z_o is typically assumed purely real for commercial transmission lines.

$$SWR = \frac{|V_{max}|}{|V_{max}|} = \frac{1+|\Gamma|}{1-|\Gamma|} \qquad (4)$$

Equation (5) defines reflection coefficient magnitude.

$$|\Gamma| = \sqrt{\frac{(R_{Load} - Z_o)^2 + (X_{Load})^2}{(R_{Load} + Z_o)^2 + (X_{Load})^2}} \qquad (5)$$

where X_{Load} is the antenna reactance and R_{Load} is the antenna resistance.

SWR can also be calculated from forward and reflected power using equation (2). The IMS employs forward and reflected power measurements to calculate SWR.

Equation (5) shows that if the antenna reactance is much greater than the antenna resistance and Z_o, the reflection coefficient, |Γ|, approaches 1. In equation (4), as |Γ| approaches 1, SWR approaches infinity, increasing maximum transmission line voltage.

Figure 2 shows that dipole antenna impedance becomes predominantly reactive below its resonant frequency of approximately 5 MHz. “In [Figure 2], the y-axis is calibrated in positive (inductive) series reactance up from the zero line, and negative (capacitive) series reactance in the downward direction. The numbers placed along the curve show the frequency in MHz. “ [4]

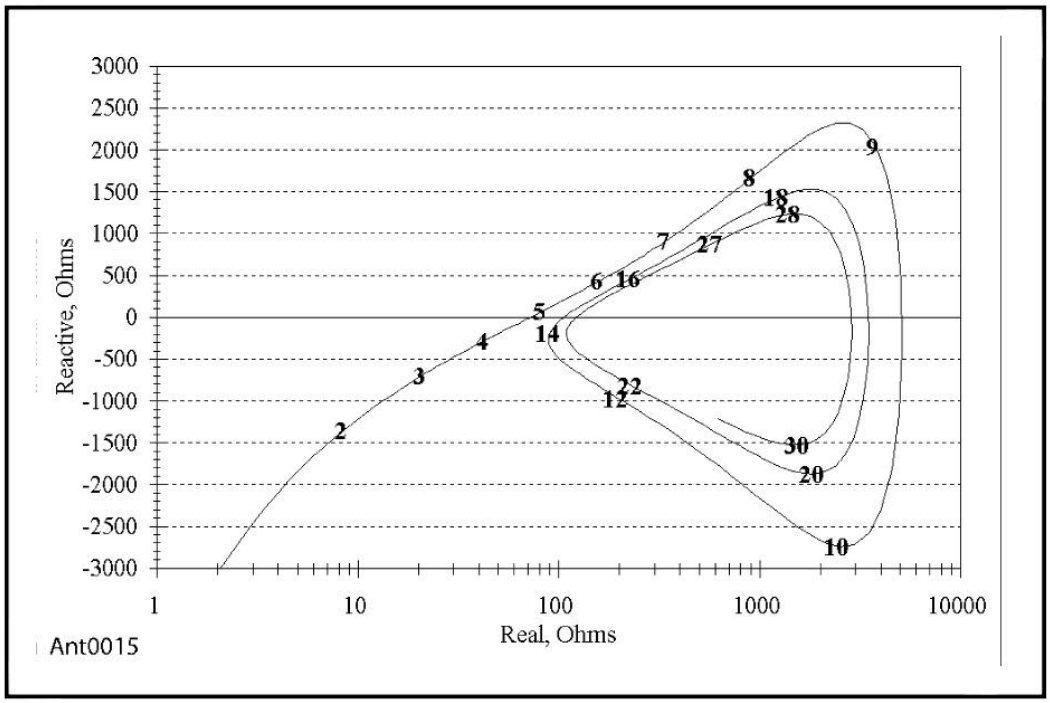

Figure 2 - Feedpoint impedance of a 100 ft long dipole antenna in free space. [4] Figure 2.10. Used with permission. Copyright ARRL.

In practice, radio operators typically use antenna tuners to match antennas for frequencies above the resonant frequency.

The IMS employs a balanced output design as opposed to unbalanced with unbalanced coaxial cable for both input and output. The problem with an unbalanced tuner is evident in Table 1 [7]. Terminating coaxial cable with highly mismatched loads results in undesirable power loss along the cable. A balanced transmission line, also called “twin lead,” conversely, exhibits lower loss when operated with mismatched loads. The IMS accepts an unbalanced line from the transceiver and internally converts it to a balanced line. The IMS to antenna transmission line is balanced. Since balanced transmission line is unshielded, unlike coaxial cable, it cannot be placed near other conductors. It must be spaced away from other conductors by at least three times the spacing between its conductors [7].

The IMS utilizes two L network matching circuit configurations. Compared to T or Pi networks, the L network uses only one combination of inductance and capacitance. This simplifies the microcontroller tuning algorithm. The disadvantage is that one L network cannot match all possible load impedances. Figure 3 shows two L network types with complimentary matching ranges on the Smith Chart. The IMS uses an RF switch to select one of the two L networks, allowing a wider matching range.

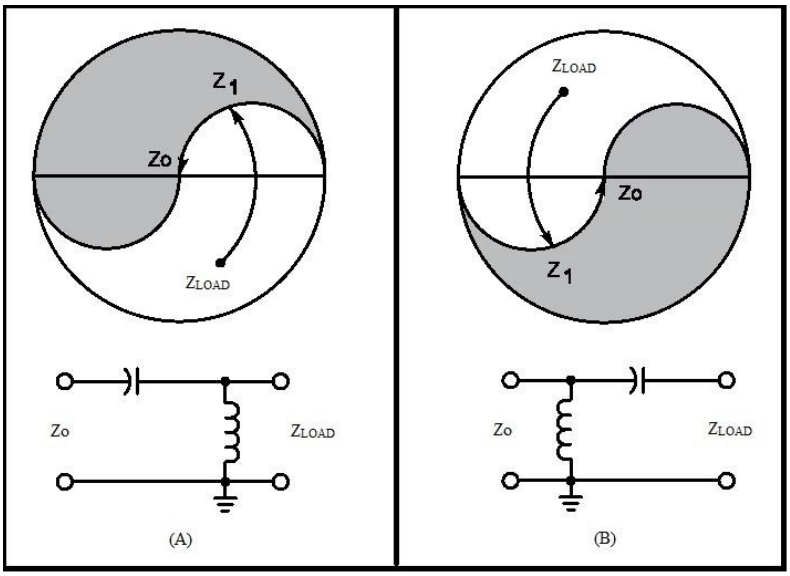

Figure 3 - Smith Chart operation and schematic for the two L network configurations [7] Figure 5.57. Used with permission; copyright ARRL. Modified from original.

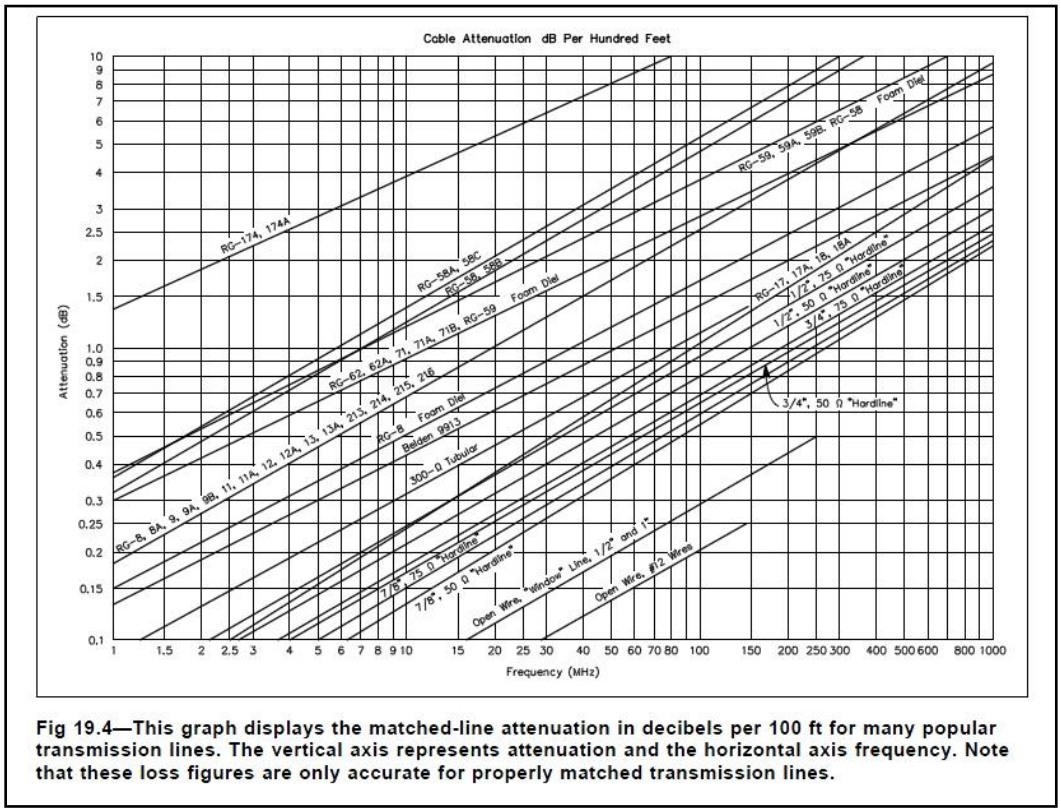

Fig 19.4—This graph displays the matched-line attenuation in decibels per 100 ft for many popular transmission lines. The vertical axis represents attenuation and the horizontal axis frequency. Note that these loss figures are only accurate for properly matched transmission lines.

Figure 4 – Transmission Line Loss Comparison [9]. Used with permission; copyright ARRL.

Figure 4 compares loss for several transmission line types. The two curves near the bottom represent two types of balanced transmission line, while upper curves represent coaxial cables. The loss for Open Wire "window" line, a twin parallel conductor balanced transmission line, is less than all types of coaxial cable for frequencies less than 200 MHz.

Chapter 3. Requirements

Table 2 defines specifications to achieve for the IMS design.

IMS REQUIREMENTS AND SPECIFICATIONS

Marketing Requirements	Engineering Specifications	Justification
1	1. Average setup time should not exceed 15 minutes	Required connections include antenna transmission line terminals, Impedance Matching System to radio transceiver coaxial cable, and 120 V AC power. (see Figure 5) The system should begin measuring RF power at power up. It will calculate SWR for RF input power greater than 3 W. To initiate automatic impedance matching, the user will press front panel button.
2	2. Parts cost should not exceed $1000	Similar impedance matching products range in market price from $200 to over $1000.Components required to build one unit must not exceed $1000. A preliminary parts search indicates total parts cost is less than $1000.
3	3. Can transfer at least 100 W of transmitter output power to a matched antenna continuously without damage.	All necessary parts are available and each can handle voltages and currents developed at 100 W RF power, the typical output power of most Amateur Radio HF transceivers.
1	4. Self-contained and portable with operating temperature range of 0° C to 70° C.	The unit will be housed in a portable (one person can carry) metal enclosure. The electronic components will be rated for commercial operating temperature range.
4	5. Antenna impedance matching range should allow matching to a dipole mounted at least 0.125 wavelength above ground and at least 0.5 wavelength long on the lowest operating frequency of 3.5 MHz.	A simple and effective portable HF antenna setup is a 140 ft wire dipole mounted 30 ft above ground. An antenna tuner should allow 3.5 MHz to 30 MHz operation on this antenna giving access to the most commonly used Amateur HF bands. One eighth wavelength for 3.5 MHz is approximately 30 ft If the antenna is closer to the ground, the feedpoint impedance approaches 0 Ω and the radiation pattern is directed upward instead of at the horizon, which is more desirable for long distance communication.

1, 3	6. The transmission line between the Impedance Matching System and the radio transceiver shall have a characteristic impedance of 50 Ω ±5%.	50 Ω is the standard antenna jack impedance on Amateur Radio HF transceivers and accompanying coaxial transmission lines. Coaxial transmission lines are unaffected when routed near metal; they can be used for outdoor unit to radio transceiver connections. The Impedance Matching System will automatically match the antenna impedance to 50 Ω.
4	7. The Impedance Matching System to antenna connection shall use terminals for a 300 to 600 Ω balanced transmission line.	Dipole, loop, and Yagi antennas are efficiently connected using a balanced transmission line with low loss in the 3.5 to 30 MHz range (see Figure 4) even when operated with unmatched loads. See Table 1, Columns 4 and 5
1,2	8. Operate using a standard 120 V AC wall outlet	Maximum power consumption occurs during matching attempts involving stepper motor operation. Stepper motor and control electronics power consumption should be below maximum of 1800 W for a 120 V AC outlet.
1	9. Must weigh less than 40 pounds	Similar products already on the market typically weigh less than 20 pounds. The weight must be less than 40 pounds for safe, single person lifting. The actual weight as built is 26 pounds.
1, 3	10. The system should warn the user if it is unable to reduce the standing wave ratio (SWR) to below 1.5:1.	Amateur Radio HF transceivers typically cannot operate with SWR greater than 2:1. Under these conditions, transceivers typically self-protect by reducing output power. The IC-706 HF transceiver manual [6] recommends less than 1.5:1 SWR. Transceivers have internal SWR meters to detect high SWR. Reflected power can increase thermal stress on the transceiver's internal power amplifier.
Marketing Requirements 1. Easy to set up and use 2. Affordable 3. Usable with most standard Amateur Radio HF transceivers 4. Works with many types of antennas		

Table 2 - IMS Requirements and Specifications Table [8], Chapter 3

Chapter 4. Design

The initial IMS was designed for an outdoor matching unit with an indoor status display and control unit. The outdoor unit simplifies routing the balanced transmission line away from metal objects as routing it inside a building is not required. Coaxial cable connects the IMS outdoor unit to the indoor radio position. This configuration exceeded cost and system complexity beyond the scope of the Senior Project. The outdoor unit requires an indoor status display unit with a separate microcontroller. Therefore, the design was revised to a self-contained indoor system with front panel status display and control. Indoor permanent installation is recommended. The location should allow balanced transmission line routing away from metal objects and ground.

Figure 5 defines the System Level Block Diagram. Inputs include electrical power and radio frequency power from the transceiver via coaxial cable. Outputs include status indicators and a balanced transmission line to the antenna. Table 3 provides additional details. While the coaxial cable and balanced transmission line are labeled input and output, they perform opposite functions when the transceiver is in receive mode.

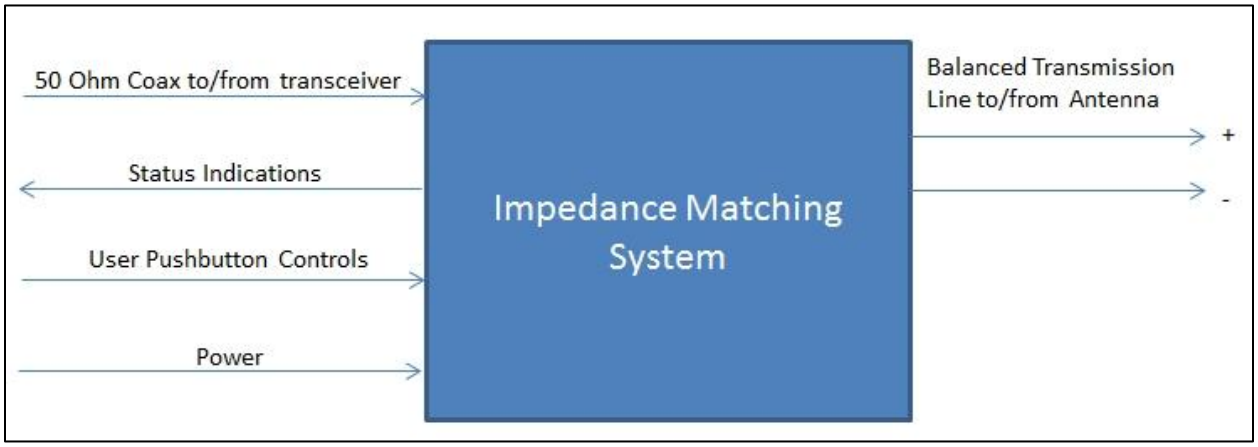

Figure 5 – System Level Block Diagram, Impedance Matching System

Table 3 – IMS System Level Functionality Table

Module:	**Impedance Matching System (IMS)**
Input	1. Power: 120 V AC at less than 10 A 2. 50 Ω Coaxial Cable from Transceiver: Carries 3.5 to 30 MHz transmit signal from the transceiver to the IMS. 3. User pushbuttons
Output	1. Balanced Transmission Line to Antenna: Carries transmit signal from the IMS to the antenna. 2. Status Indicators: An LCD provides user with current value of Voltage Standing Wave Ratio (VSWR), , forward and reflected power, inductor & capacitor relative positions (i.e. minimum and maximum inductance or capacitance), and RF Switch Position.
Functionality	Senses greater than 1.5:1 VSWR during transmit and adjusts internal reactance to match antenna transmission line impedance to the 50 Ω transceiver coaxial connection.

Figure 6 defines the IMS Subcomponent Block Diagram.

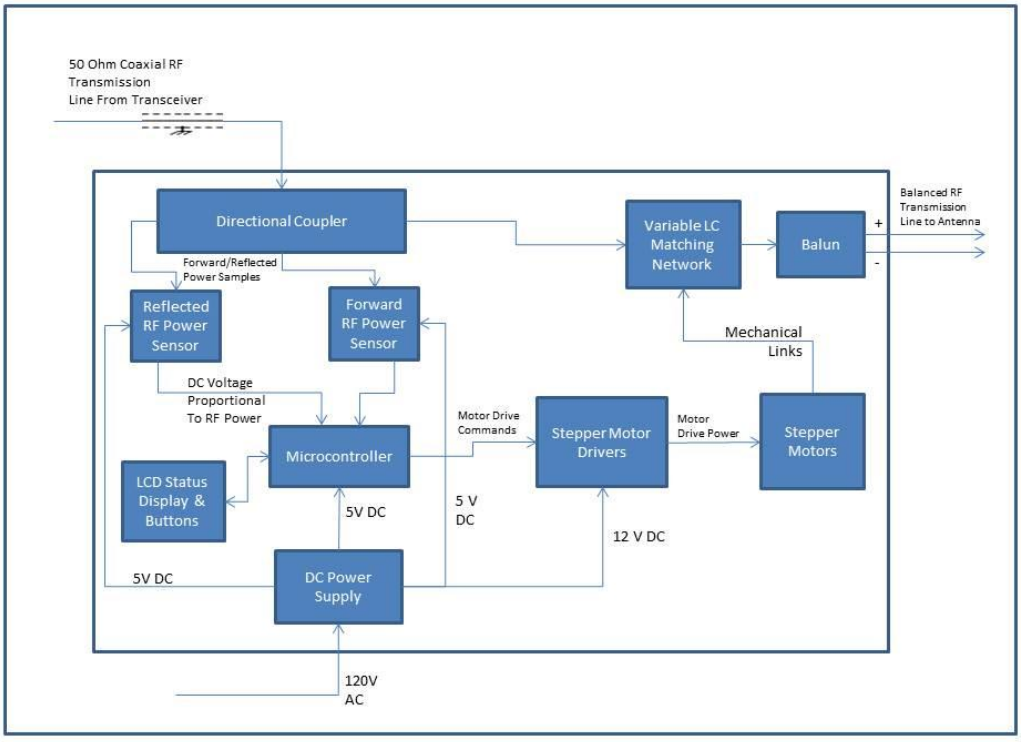

Figure 6 – IMS Subcomponent Block Diagram

Table 4 describes subcomponent inputs, outputs, and functionality.

Table 4 – IMS Subcomponent Level Functionality Table

Module		Description
Forward/Reflected RF Power Sensor	Input	1. Radio Frequency Power from Directional Coupler. 2. 5 V DC Power
	Output	1. DC Voltage Proportional to RF Power
	Functionality	Produces two DC voltage outputs: one proportional to the forward RF power and one proportional to reflected RF power.
Directional Coupler	Input	1. RF Power from Transceiver
	Output	1. RF Power to LC matching network 2. Forward Power Sample to Forward RF Power Sensor 3. Reflected Power Sample to Reflected RF Power Sensor
	Functionality	Provides 30 dB reduced samples of the forward and reflected RF power to allow RF power sensor power measurement
Balun	Input	4. RF power via unbalanced coaxial transmission line
	Output	1. RF power via balanced transmission line
	Functionality	A Balun is a transformer that converts an unbalanced line to a balanced line.
Variable LC Matching Network	Input	1. RF power from Directional Coupler 2. Mechanical Actuation from Stepper Motors
	Output	1. RF Power to Balun
	Functionality	The LC Matching network is a shunt variable inductor and a series variable capacitor that each provide the necessary reactance to achieve an impedance match. A single pole, double throw RF switch places the shunt inductor on either side of the capacitor to match a wider range of impedances.
Microcontroller	Input	1. DC Voltage Proportional to RF Power 2. DC Power 3. User Pushbutton Controls
	Output	1. Stepper Motor Drive Commands 2. Data to LCD Status Display
	Functionality	The microcontroller measures DC voltage from the RF power meter and issues motor drive commands to adjust the LC network for an impedance match. It also provides serial data to display RF power level and tuning status.
DC Power Supply	Input	1. 120 V AC power
	Output	1. DC power: 12 V at 2 A and 5 V at 1 A.
	Functionality	Converts 120 V AC to 12 V and 5 V DC power for the circuitry and stepper motors.
Stepper Motor Drivers (3)	Input	1. Motor Drive Commands from Microcontroller 2. DC Power
	Output	1. Motor Drive voltage
	Functionality	Provides motor power based on commands received from the microcontroller.
L and C Stepper Motors	Input	1. Motor Drive Power
	Output	1. Mechanical Rotation
	Functionality	There are three stepper motors: The L and C motors adjust the variable inductor and capacitor, and a linear actuator motor controls the RF switch in the matching network
LCD Status Display	Input	1. Data from microcontroller 2. DC Power
	Output	1. Display information
	Functionality	The Status Display Unit displays forward and reflected power and tuning status received from the microcontroller.

Directional Coupler

A directional coupler is an RF power measurement device with four ports: RF input, RF output, forward coupled (or sampled), and reflected (or reverse) coupled. A directional coupler samples a portion (coupling factor) of RF power in the forward and reverse directions. The coupling factor (separate values for forward and reverse directions) is the ratio of actual to sampled RF power. The RF input and output ports are connected by a main (through) line and the forward and reflected coupled ports are connected by a coupled line. A portion of the main line RF power is diverted to the coupled line where it is attenuated by a fixed value known as the coupling factor (ratio of actual to sampled RF power). The coupling factor is high, ~1000 or 30 dB, to minimize main line power loss. The forward coupled port power is coupled in phase with the main line forward power and out of phase with main line reflected power, further attenuating reflected power by a factor known as directivity. The opposite case is true for the reflected coupled port. The directivity is the power ratio of the forward to reflected coupled ports with the through port terminated in a matched ($\Gamma = 0$) load. Directivity is ideally infinite since there should be no reflected coupled power for a matched load at the through port. The directional coupler allows transmission line forward and reflected power measurement using sensitive low power electronics while minimizing main line power loss.

The IMS employs a directional coupler for forward and reflected power measurement and SWR calculation. The directional coupler enables 200 W power measurements using the AD8307 logarithmic detector IC, which has a +17 dBm (50 mW) maximum power input. [10] A directional coupler design by W. T. Kaune [11] shown in Figure 7 utilizes inexpensive components.

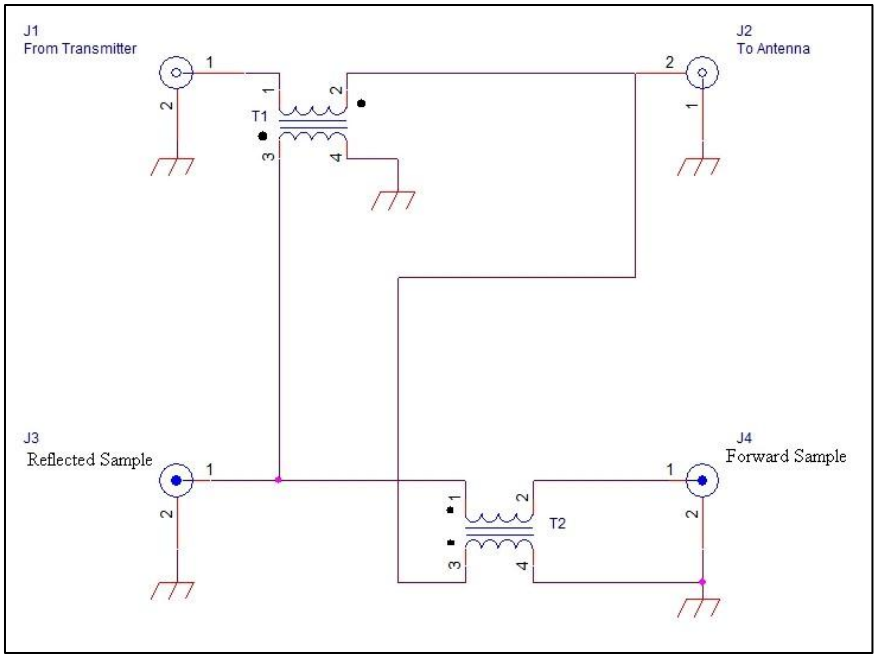

Figure 7 - Directional Coupler Circuit Diagram [11]

Ferrite toroids wound with AWG 26 wire and surrounding two 2" sections of RG-8 50 Ω coaxial cable form the coupling transformers. The shield conductor of the coaxial cable through the toroids prevents capacitive coupling between the transmission line and windings. Double sided circuit board provides additional shielding to prevent unwanted RF coupling.

Directivity is the ratio of forward to reflected coupled power when the directional coupler is terminated with matched (Γ=0) loads. Ideally, directivity approaches infinity since the reflected coupled port power should be zero for a matched load. Commercial HF directional couplers offer directivities from 15 to 44 dB. [12] [13] Kaune [11] claims a directivity of 35 dB at 3.5 MHz and 28 dB at 30 MHz.

RF power levels, in W and dBm (dB referenced to 1mW) are defined in equations (6) and (7).

$$P(dBm) = 10\,log_{10}[P(mW)] = 10\log_{10}[1000([P\,(W)])] \quad (6)$$

$$P\,(W) = \frac{10^{\left[\frac{P(dBm)}{10}\right]}}{1000\,\frac{mW}{W}} \quad (7)$$

The directional coupler provides a forward coupled power output 30 dB less than the forward transmitter power. For 100 W (50 dBm from equation (6)) forward power, the forward coupled power should be 20 dBm. With 28 dB of directivity, the reflected coupled port is:

20 dBm -28 dB = -8 dBm = 0.16 mW (8)

Using equation (2) to calculate SWR from forward and reflected power, the SWR measured using this directional coupler is 1.08 and 1.03 for 28 dB and 35 dB of directivity, respectively.

Power Supply

Four devices require power: the microcontroller, the power sensors, the LCD, and the stepper motor drivers. The stepper motor drivers require 12 ± 1 V at 1 A. Table 5 defines the 5 V supply requirements.

5 V DC Power Supply Requirements		
Device	Voltage Range, V	Maximum Current, mA
ATmega32 Microcontroller [14]	4.5 to 5.5	200
AD8307 Power Sensor, Quantity 2 [10]	2.7 to 5.5	20
LCD [15]	4.7 to 5.5	165
Power Supply Requirement	4.7 to 5.5	385

Table 5 - 5 V DC Power Supply Requirements

The supply current capability is increased to 1 A for the 5 V supply and 2 A for the 12 V supply for improved reliability. A power supply providing half its current capability will outlast one supplying full capacity.

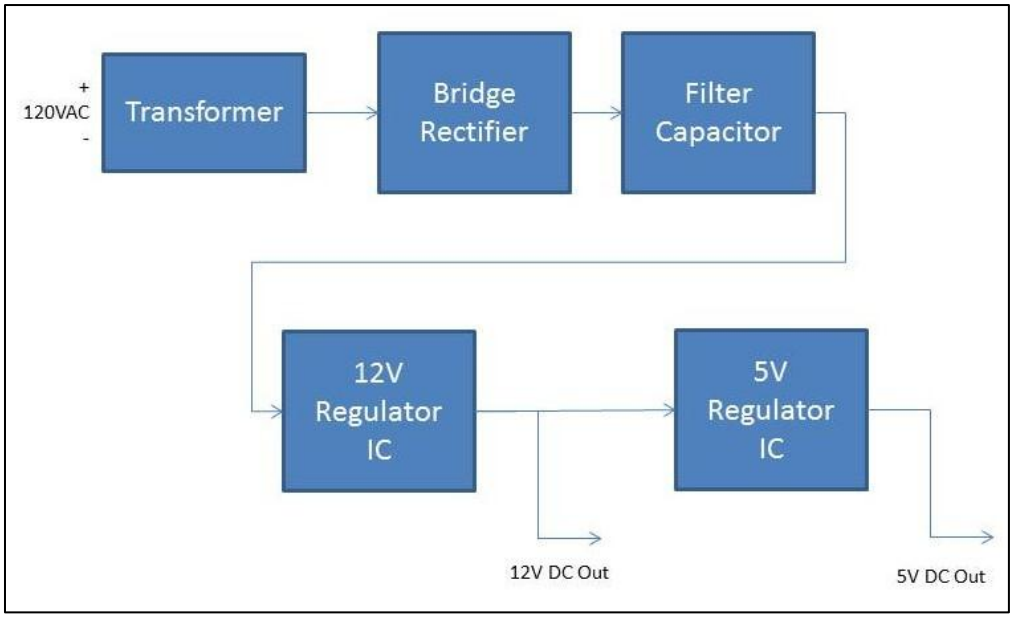

Figure 8 - Power Supply Block Diagram

Figure 8 shows the power supply conceptual block diagram. A 120 V/25.2 V 2 A center tapped transformer was selected. The center tap provides (25.2 V)/2 or 12.6 V AC RMS. Though only a 2 A rectifier was required, a 4 A bridge rectifier was selected for reliability. Fixed voltage linear

three terminal regulators were selected: ST Microelectronics L78S12 12 V, 2 A regulator [16] and Texas Instruments TL780-05 5 V, 1.5 A regulator [17]. Both feature short circuit and thermal overload protection.

The filter capacitance was determined as follows.

The transformer peak voltage output is:

$$V_{peak=}\sqrt{2}V_{RMS} = \sqrt{2}\,(12.6\,V) = 17.8\,V \quad (9)$$

Assuming 2 x 0.7 V diode voltage drop, the bridge rectifier output is 17.8 V - 1.4 V = 16.4 V

The L78S12 voltage regulator IC has a required minimum input voltage of 14.5 V. Thus, the maximum voltage ripple is 16.4 V – 14.5 V = 1.9 V.

Assuming maximum supply current of 2 A; equation (10) gives the required capacitance.

$$C = \frac{I}{2fV_{ripple}} = \frac{2\,A}{2(60\,Hz)1.9\,V} = 8800\,\mu F \quad (10)$$

Thus, two 4700 µF capacitors in parallel form the filter capacitor.

Balun

A balun transforms a balanced line to an unbalanced line. The IMS input and matching network are unbalanced, meaning one terminal is at ground potential. The balun at the IMS output enables balanced transmission line use for the IMS to antenna connection. The ARRL Handbook [7] provides a suitable balun design shown in Figure 9.

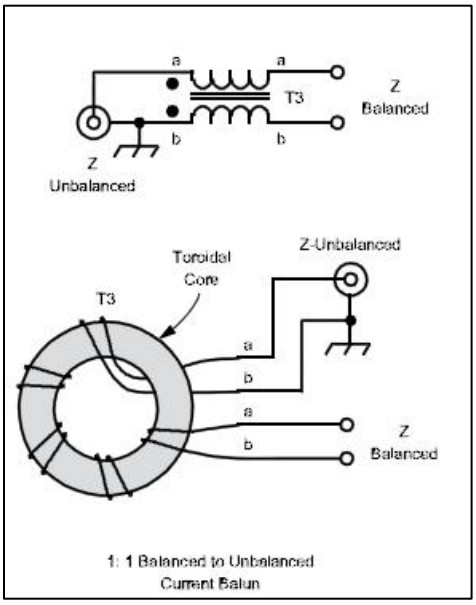

Figure 9 - 1:1 Balun Design [5] Figure 20.23A. Used with permission; copyright ARRL

The design calls for 12 bifilar turns of AWG 14 enamel insulated wire on a 2.4 inch outer diameter mix type 31 or 43 ferrite toroid. A 1:1 balun does not transform impedance. With the balanced terminals connected to a 50 Ω load, the unbalanced terminal impedance is also 50 Ω.

RF Power Sensor

An RF power sensor design by W. T. Kaune [11] , shown in Figure 10, utilizes the Analog Devices AD8307 Log Amp Detector IC, which outputs a DC voltage proportional to RF input power from -75 dBm to +17 dBm. Equation (11) yields this relation. [10]

$$V_{out} = 0.025\big(P_{in}(dBm)\big) + 2 \quad (11)$$

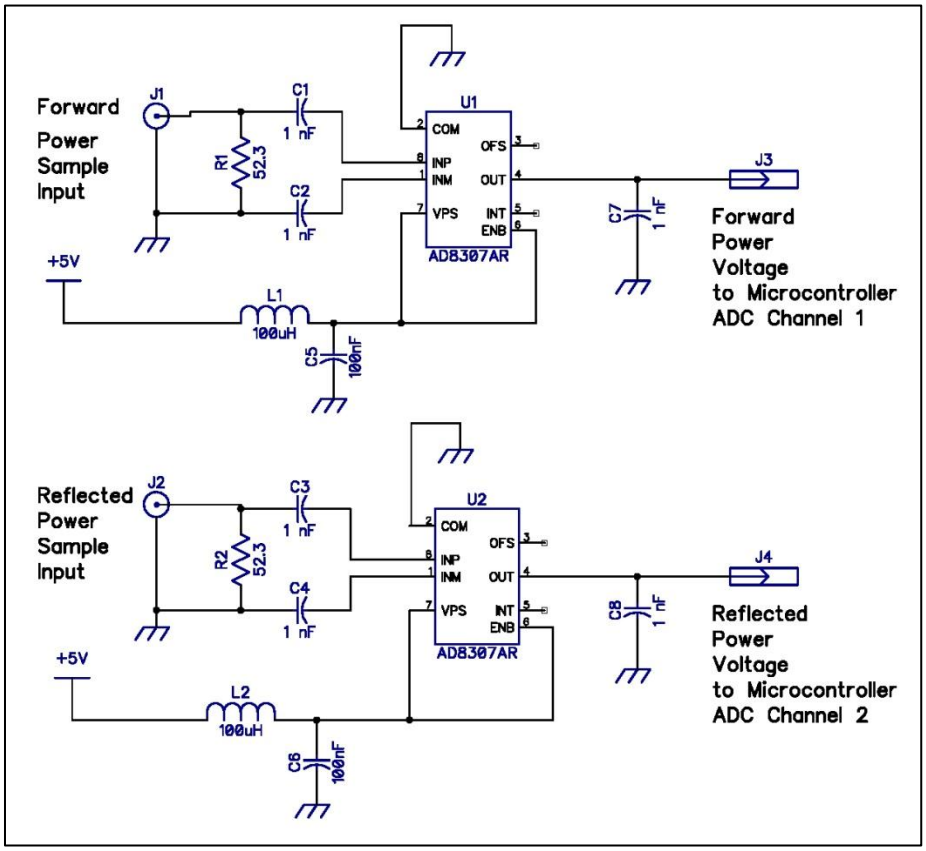

Figure 10 - RF Power Sensor Design [11]

Microcontroller

The Atmel Atmega32 microcontroller IC was selected due to previous experience in CPE-329. It features 32 programmable I/O pins, 32 kB non-volatile program memory, and an eight channel, 10 bit analog to digital converter (ADC). The internal ADC allows direct connection of the RF sensor output.

LCD

A two line by 16 character LCD displays forward & reflected power in W, SWR, inductor & capacitor positions, and RF switch position. The LCD requires 11 connections to the microcontroller.

Stepper Motors

The stepper motors were the largest available from Sparkfun.com, with 125 oz.-inches of torque [18]. They are rated at 2 A at 3 V. The torque required to rotate the capacitor and inductor was unknown since a measurement device was not available. Therefore, motor adequacy was determined by actuating the capacitor and inductor components. A third stepper motor is a linear actuator that controls the matching network RF switch [19].

Novel/Innovative Features

The matching network features a switch to select one of two possible L network configurations: series C shunt L and shunt L series C. The switch places the shunt inductor on either the source or load side of the capacitor. One L network configuration can only match half of all possible loads. The switch enables matching all possible loads by allowing both L network configurations. While the switch could have been implemented using a relay, this option requires power to maintain the relay in its default position. Latching relays, which remain in either set position with power removed are available, but a linear actuator stepper motor was already on hand. The linear actuator positions a rod in one direction or in the opposite direction. Its rotor shaft is a threaded tube with a threaded rod inserted. If the threaded rod is prevented from spinning with the rotor shaft, the rotor threads the rod in one direction depending on the rotation direction. The rod is attached to the switch's moving contact positioning it to connect to either stationary contact.

Stepper Motor Driver

The "Big Easy Driver" [20] operates bipolar stepper motors up to 2 A and 8 – 30 V. Microcontroller interfacing requires three output pins to control three functions: Step, Dir, and Enable. "Enable" turns on the driver and applies motor drive current. "Step" rotates the motor one step for each rising edge. "Dir" defines "Step" rotation direction; clockwise or counterclockwise.

Chapter 5. Test Plans

Directional Coupler

Test 1:
The directional coupler should not present greater than 1.5:1 SWR at its RF input with its outputs terminated in 50 Ω (Γ = 0) loads. Measure RF input SWR using a vector network analyzer over the 3.5 to 30 MHz frequency range with all outputs terminated in 50 Ω.

Test 2:
The coupling factor (ratio of actual to sampled RF power) should be 30±1 dB [11]. Connect an RF signal generator set to 0 dBm to the RF input port and measure the forward coupled port output power using a spectrum analyzer to determine the coupling factor. Ideally, the coupling factor should not vary by more than 1 dB from 3.5 to 30 MHz.

Test 3:
Minimum directivity, equation (12) below, is 28 dB [11]. Connect an RF signal generator set to 0 dBm to the RF input port and terminate the RF output port in 50 Ω. Measure the RF power at the forward and reflected coupled ports using a spectrum analyzer.

$$Directivity, (dB) = [fwd.coupled\ pwr, (dBm)] - [refl.coupled\ pwr, (dBm)] \qquad (12)$$

Minimum directivity is 28 dB over 3.5 to 30 MHz range.

RF Power Sensor

Verify that the DC output voltage conforms to equation (13) from -75 dBm to +17 dBm.

$$V_{out}, (V) = A\big(P_{in}, (dBm)\big) + B, (V) \qquad (13)$$

Where A = 23 – 27 mV/dB and B = 1.9 – 2.2 V [10]

Connect an RF signal generator to the sensor RF input and measure the DC output voltage for power levels from -75 dBm to +17 dBm at 3.5, 15, and 30 MHz.

DC Power Supply

Test power supply for output voltage regulation under no load and full load conditions. Full load is 0.5 A and 1 A for the 5 V and 12 V supplies, respectively. Apply 120 V AC input power and measure the 5 V and 12 V supply output voltages for the no load condition. Connect a 10 Ω, >2.5 W resistor to the 5 V output and a 12 Ω, >12 W resistor to the 12 V output. Measure the 5 V and 12 V supply output voltages for the full load condition. The no load and full load voltages should not exceed the voltage regulator datasheet specifications of 0.05 V and 0.6 V for the 5 V and 12 V supplies, respectively. [16] [17].

Stepper Motors

Rotate the variable capacitor and inductor using the stepper motors. Rotation will not occur if the required torque exceeds the 125 oz/inch motor rating.

LC Matching Network

Connect a 50 Ω dummy load to the matching network output and a 3.5-30 MHz transmitter and SWR meter to the input. Manually tune the matching network from 3.5 to 30 MHz. The matching network should achieve maximum 1.5 SWR matching from 3.5 to 30 MHz.

Microcontroller

The microcontroller IC is tested using the Atmel STK-600 microcontroller development board. The USB powered STK-600 has a plug in socket for the microcontroller IC. The microcontroller pins are routed to pins on the board which can be connected to onboard LED's and switches. The STK-600 can also program the microcontroller via the USB connection. The microcontroller is programmed to illuminate the LED's to verify all the port pins. The IMS microcontroller circuit board is tested with the same LED blink program.

LCD

A program displaying upward counting numbers verifies LCD functionality.

Automatic Impedance Matching

The impedance of a 120 ft dipole antenna connected using 90 ft of 450 Ω balanced transmission line is measured from 3.5 to 30 MHz using a vector network analyzer. With the IMS connected to the dipole, attempt automatic impedance matching for center and edge frequencies in all Amateur radio bands from 3.5 – 30 MHz. Table 7 lists the bands.

Table 6 – Amateur Radio HF Bands

Amateur Radio HF Bands	
Approximate Wavelength, M	Frequency, MHz
80	3.5 – 4.0
40	7.0 – 7.3
30	10.1 – 10.15
20	14.0 – 14.35
17	18.068 – 18.168
15	21.0 – 21.450
12	24.89 – 24.99
10	28.0 – 29.7

Dipole impedance values for frequencies where maximum 1.5 SWR matching is achieved are plotted on a Smith chart. The impedance range for maximum 1.5 SWR matching is determined using the Smith chart.

Chapter 6. Development and Construction

Chassis

The main chassis was salvaged from a General Electric Mobile Radio MastrII® Base Station power supply [21]. The chassis provides interior dimensions of 15.5" x 10.25" x 6". All interior components were removed. For easier drilling, the steel front and rear panels were replaced with 0.125" thick aluminum sheets matching the dimensions of the original panels. A 14.5" x 9.25" aluminum panel was bolted to the interior bottom to serve as an attachment point for all IMS components. Mounting holes were drilled and tapped in this panel allowing all component mounting screws and bolts to be threaded directly into the sheet. Rubber bumpers were bolted to the chassis underside to prevent sliding and scratching of tables and counter tops.

Directional Coupler

Figure 11 shows the completed directional coupler. Except for copper tape used to secure the circuit board shields, it was built as specified by Kaune [11].

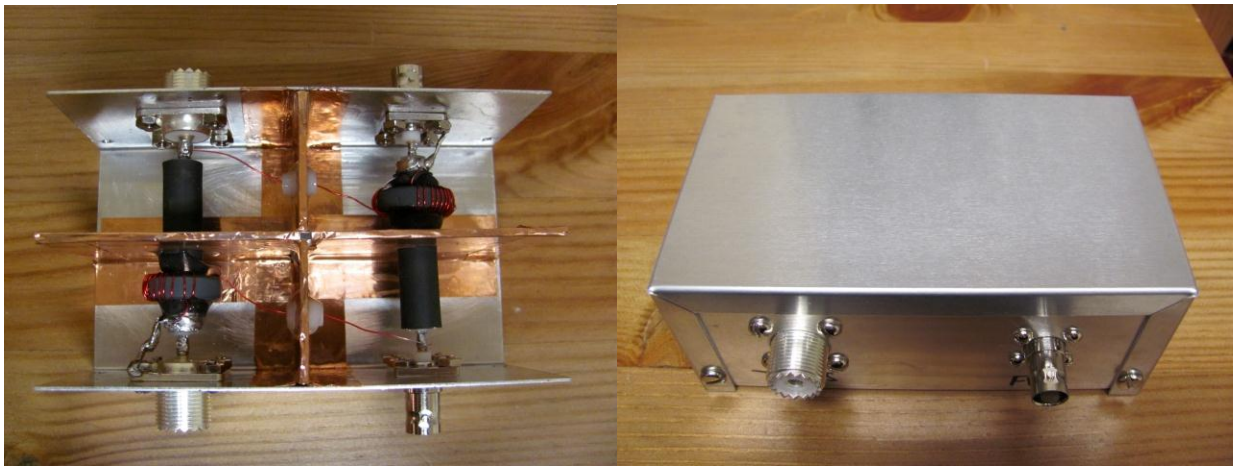

Figure 11 – Directional Coupler

Power Supply

All power supply components were grouped in the rear left corner to minimize space. The power switch and fuse holder were salvaged from the General Electric power supply [21]. The power supply circuit board, shown in Figure 12, was mounted to the rear panel with the voltage regulators bolted to the panel for improved heat dissipation.

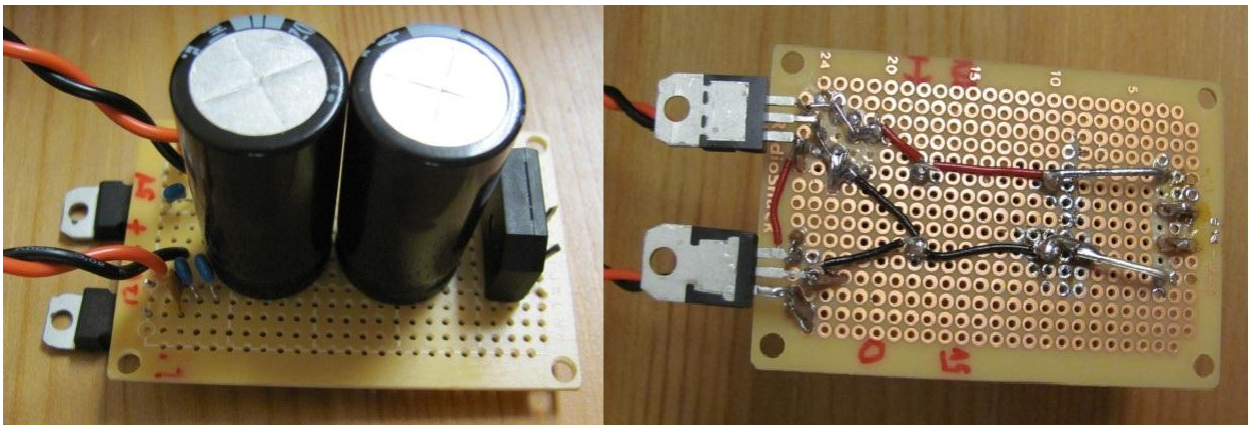

Figure 12 - Power Supply Circuit Board

Figure 13 shows the complete power supply. The power switch, fuse holder, and AC power cord plug (male IEC plug) were mounted to the IMS rear panel. Heat shrink tubing and liquid electrical tape on 120 V AC wires and terminals mitigate electrical shock and short circuit hazards. The transformer is bolted to the chassis bottom plate.

Figure 13 - IMS Power Supply

Matching Network

Figure 14 shows the complete matching network. The variable capacitor was salvaged from a manual antenna tuner and the inductor was purchased new. The inductor and capacitor motor mounts were fabricated from an aluminum project box. Motor positioning was critical to ensure alignment with the inductor and capacitor rotation axis preventing wobble during rotation. One inductor terminal is grounded to the chassis at its mounting bracket. The other terminal connects to the movable contact of the RF switch.

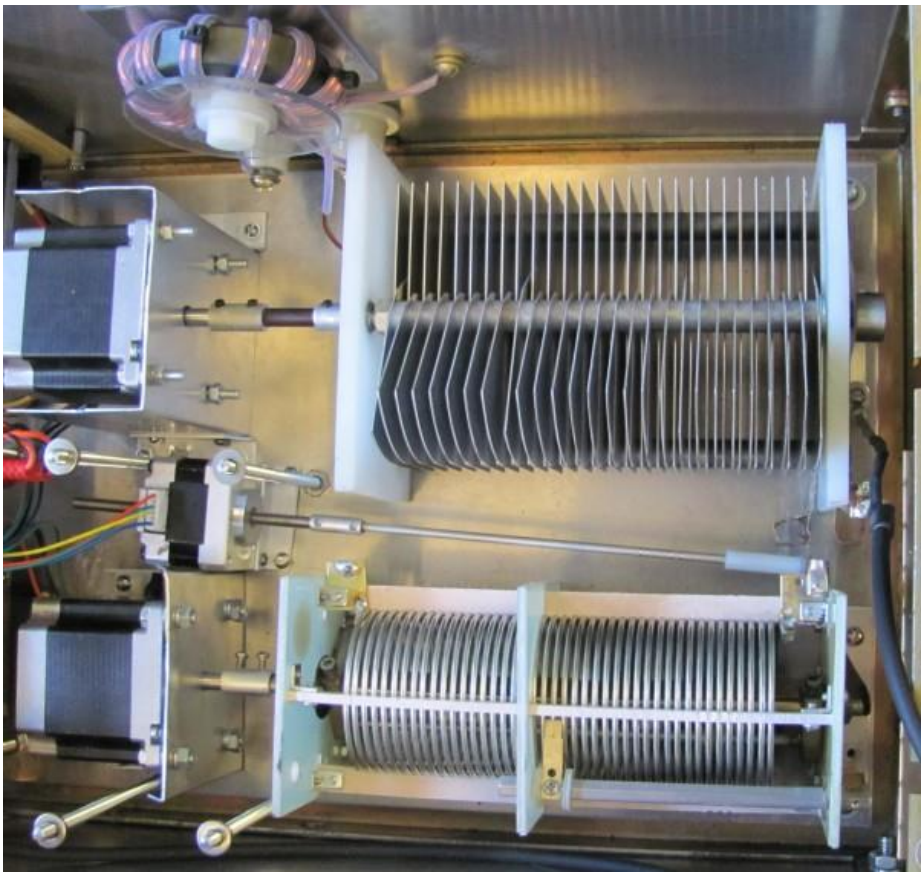

Figure 14 - IMS Matching Network

Figure 15 shows the RF switch built for the matching network.

Figure 15 - Matching Network RF Switch

The switch has two stationary contacts connecting to either the load side or source side of the capacitor. A threaded nylon spacer connects the push rod to the movable contact insulating the contact from the grounded rod.

Balun

The 1:1 balun was built as shown in Figure 9. Figure 16 shows the completed balun.

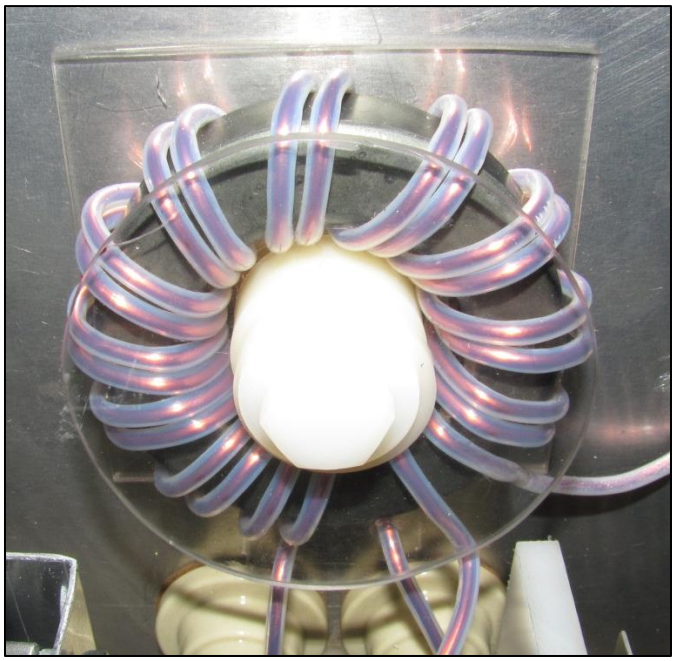

Figure 16 - IMS Balun

The wire is Teflon insulated to prevent arcing. A square polycarbonate sheet insulates the balun from the rear panel and a round sheet serves as a washer to hold the balun in place. Nylon washers, a bolt, and a nut fasten the balun to the rear panel.

RF Power Sensors

The two RF power sensors, forward and reflected, were built on pre-fabricated PCB's from Far Circuits [22]. A shielded box was constructed using copper clad PCB to minimize RF interference to the sensors. Figure 17 shows the completed RF power sensors in the shielded box. The box lid attaches with four screws and is removed for the photo.

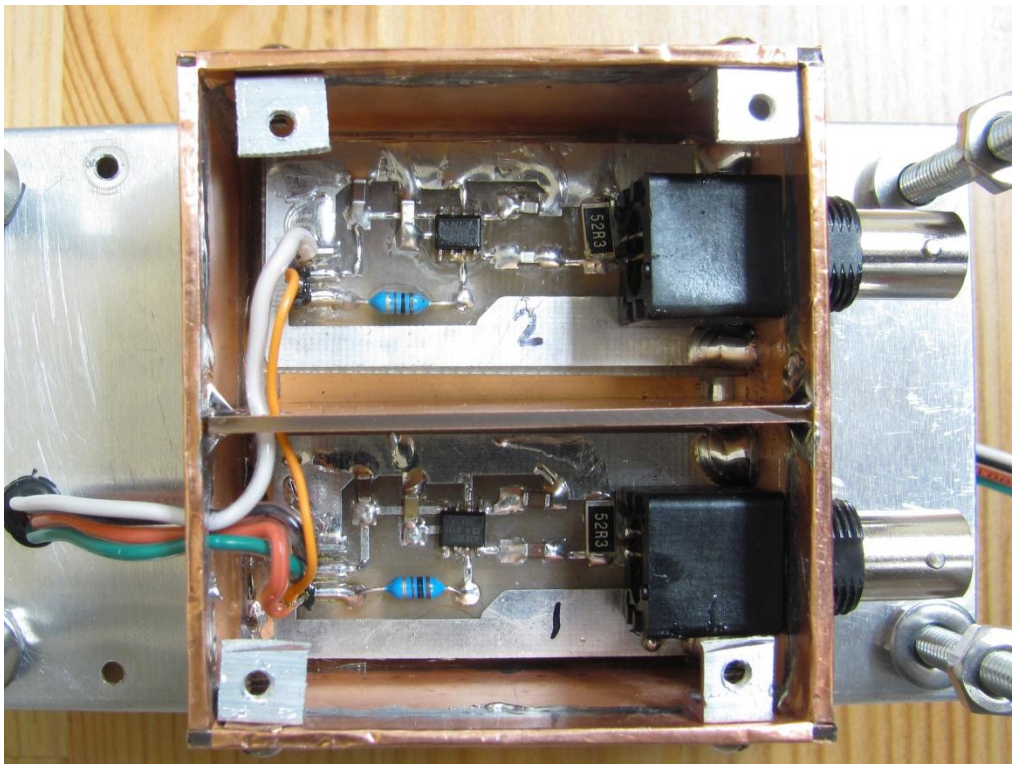

Figure 17 - RF Power Sensors

The RF power sensor module is attached to the bottom of the microcontroller module using screws and nuts. The power, ground, and sensor voltage wires route inside the microcontroller module where they are soldered in place. The microcontroller and RF sensor modules are removable from the IMS as one unit.

Microcontroller Module

The microcontroller circuit was built on a prototyping perf board. A 40 pin IC socket was soldered to the board to facilitate microcontroller replacement. Figure 18 shows the bottom of the microcontroller circuit board and the solder connections.

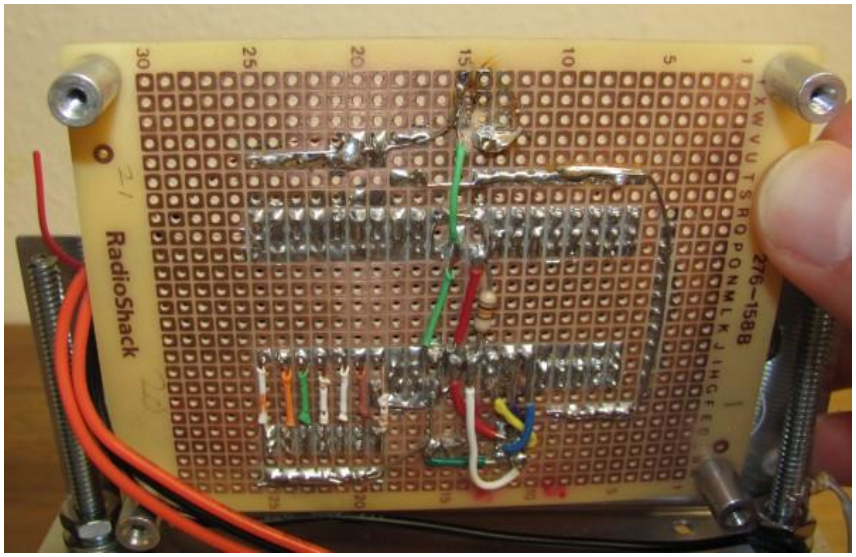

Figure 18 - Bottom of Microcontroller Board

Header pins were wired to the microcontroller I/O pins providing connection points for system development. Permanent I/O connections use wire wraps to the header pins.

To allow software modification, a 2 row by 3 pin male header plug was installed on the circuit board and connected to the microcontroller "In System Programming" (ISP) interface. A computer USB interface allows microcontroller software programing. Figure 19 shows the completed microcontroller module.

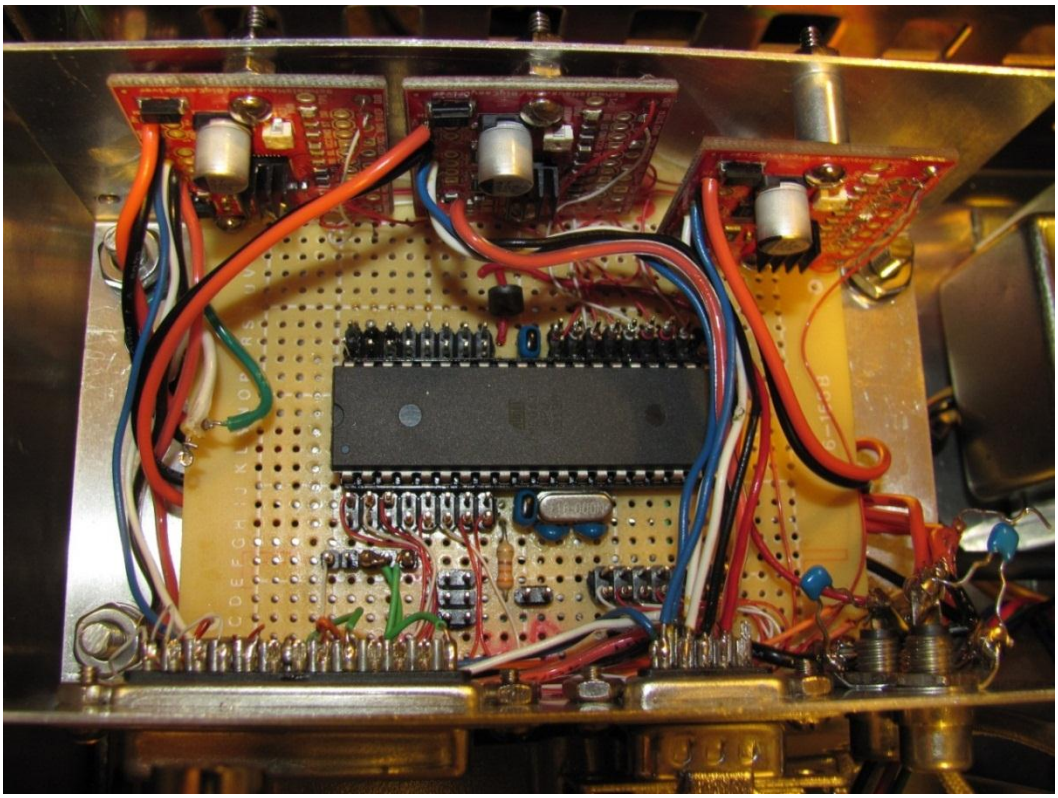

Figure 19 - Microcontroller Module

The microcontroller board is attached to the floor of an aluminum project box using screws and 0.5” standoffs. The three stepper motor drivers are mounted along one wall in the box. Connectors installed on the box interface the module to the IMS. A DB25 connector connects to the IMS front panel LCD and buttons. A DB15 connector connects all three stepper motors. 12 V and 5 V DC power are supplied to the module via RCA connectors. Table 7 lists all connections made to the microcontroller pins.

Atmega32 Microcontroller Pin Connections				
Pin Number	Pin Name	Input/Output	Destination	Use
1	Port B - 0	Output	Front Panel LCD Via DB25 Pin 24	LCD Register Select (RS)

Table 7 - ATmega32 Microcontroller Pin Connections

Front Panel

The front panel LCD and buttons are connected to the microcontroller module via a 25 conductor cable. At the front panel, the cable wires are soldered to the buttons and LCD pins. The other end of the cable has a male DB25 connecting to the microcontroller module female DB25 allowing quick module removal. The LCD backlight requires 4.2-4.6 V DC power. To get this voltage, a 1N4001 diode was soldered in series with +5V DC wire and the backlight power pin. Assuming a minimum 0.5 V diode voltage, 4.5 V is supplied to the backlight. Figure 20 shows the complete IMS front panel.

Figure 20 - IMS Front Panel

Rear Panel

Figure 21 shows the IMS rear panel.

Figure 21 - IMS Rear Panel

Ceramic insulators isolate the balanced antenna transmission line terminals from the panel. A ground terminal provides an earth ground connection point for the chassis. The ground and antenna terminals use wing nuts allowing connection without tools. The IMS connects to a transmitter or transceiver via an SO-239 connector. The rear panel also contains the IMS power switch, power supply fuse holder, and 120 V AC connector.

Complete IMS

Figure 22 shows the IMS interior with all hardware construction complete. All internal RF connections on the source side of the matching network were made using RG-58 50 Ω coaxial cable. Copper tape covers the LCD backside for RF shielding.

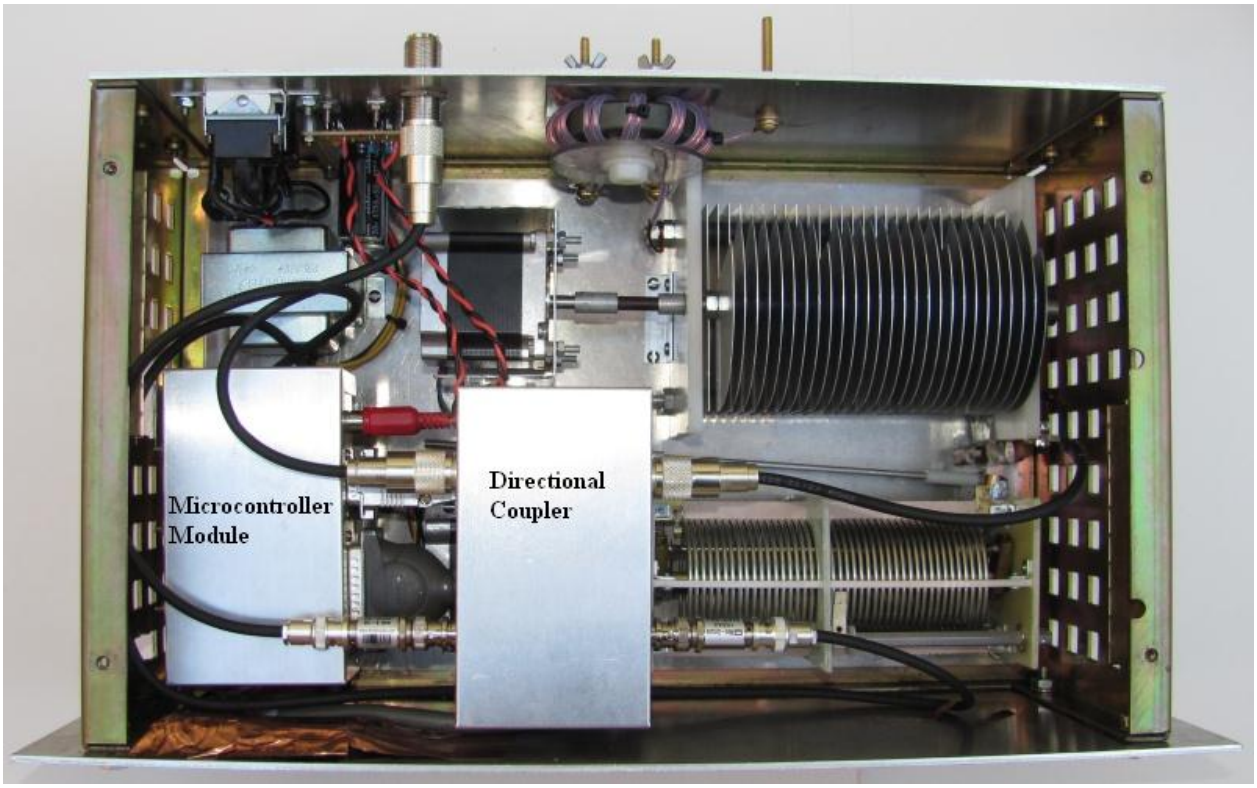

Figure 22 - IMS Interior

Software

The software was written after all hardware construction was complete. The completed software is shown in Appendix E. One feature at a time was enabled in the following order:

1. LCD Status Display
2. Manual Stepper Motor Control via Front Panel Buttons
3. Forward and Reflected Power Measurement and SWR Calculation
4. Automatic Impedance Matching

A more detailed software development discussion for these four features follows.

LCD Status Display

The LCD displays two lines of data with 16 characters each. Excel was used for display design. Figure 23 shows the Excel sheet.

1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
F	_	_	_		R	_	_		S	W	R	_	_	.	_

>	L	_	_	_	_		C	_	_	_		S	L	S	C

Figure 23 - Excel Sheet LCD Display Configuration

A software function named “Update_Display” was written to write data to the display. LCD display software functions previously developed in the CPE-329 course were incorporated into the program.

Figure 24 shows the actual display.

Figure 24 - LCD Display

On the display, the number following “F” is the measured forward power in W. The number following R is the reflected power in W. SWR is calculated from the forward and reflected power and the result is displayed after the letters “SWR.” The number of motor steps counting up from minimum inductance and capacitance values are displayed after “L” and “C,” respectively. One of two possible RF switch positions, SCSL and SLSC, is displayed in the

lower right. The two possible positions are Series C-Shunt L, and Shunt L-Series C. This refers to the shunt inductor (L) being either on the source or load side of the series capacitor.

Manual Stepper Motor Control via Front Panel Buttons

A function named “check_buttons” was written to allow user manual stepper motor control. This allows user selection and actuation of individual stepper motors for the adjustable inductor or capacitor, or the RF switch.

The front panel “Select” button selects which motor to control. The “greater than” symbol (“ > ”) appears on the LCD indicating the selected motor. If the user presses the select button once, the “ > “ symbol appears in front of “ L” indicating that the inductor motor is selected. Pressing “Select” again places “ > “in front of “C” which indicates capacitor motor selection. Pressing “Select” a third time moves “ >” in front of the “SLSC”/”SCSL” switch position indicating that the switch motor is selected. Pressing “Select” a fourth time removes “ > “from the display indicating that no motor is selected.

When each motor is selected, the ENABLE line to the respective motor driver transitions from logic high (5 V) to low (0 V) causing the motor driver to apply power to the motor. With motor power applied, 12 V DC supply current is 1 A. To reduce power consumption, the software has a timer which de-selects a selected motor if no button has been pressed for ten seconds. With either the capacitor or inductor motor selected, the user presses the “Select +” button to increase capacitance or inductance. The “Select – “ button decreases inductance or capacitance. With the switch motor selected, pressing “Select +” toggles the switch position and the “SCSL”/ SLSC” display indication.

As the inductor or capacitor changes position, the displayed relative position values update. These values indicate the number of motor steps counting up from the minimum inductance and capacitance positions. The inductor value range is 0 to 8500 and the capacitor range is 0 to 1660.

Initial stepper motor testing determined 3200 steps per revolution rather than 200, the datasheet-specified number of steps per revolution. The motor driver instruction manual specifies that the drivers default to 1/16th step increments and that three pads on the driver require grounding to attain full steps. (16 * 200 steps/rev = 3200 steps/rev). Matching network testing determined optimum values of 200 steps/rev for the inductor and 3200 steps/rev for the capacitor.

Initially, the system did not recall motor position following a power cycle. The system must record position to avoid exceeding mechanical limits. Software functions were written to store the position values in the ATmega32 non-volatile EEPROM memory. EEPROM cells have a lifetime of 100,000 writes before failure; therefore the program must reduce EEPROM writing. The program writes values 10 seconds after the user has pressed any button and only if the values differ from those previously stored.

Forward and Reflected Power Measurement and SWR Calculation

A function named "Calculate_SWR" was written to obtain forward and reflected power values from the analog to digital converter (ADC) and convert them to power in W and SWR. Equation (14) [10] yields the RF power sensor output voltage for a given input power in dBm, P_{dbm}.

$$V_{out}, V = 0.025(P_{dBm}) + 2 \qquad (14)$$

For a 10 bit ADC, the number of possible output values is 2^{10} or 1024 numbers from 0-1023. Equation (15) gives the ADC decimal output value based on the ADC input voltage, V_{in}, and the ADC reference voltage, V_{REF}. [14]

$$ADC = 1024\left[\frac{V_{IN}}{V_{REF}}\right] \qquad (15)$$

The ADC input voltage is the power sensor output voltage from equation (14). The reference voltage, V_{REF}, was set to the ATmega32 internal 2.56 V bandgap voltage reference.
ADC V_{IN} = power sensor V_{out}.

A microcontroller limitation is the inability to perform floating point math; only integer numbers can be processed. To overcome this limitation, a lookup table (LUT) was created. Table 8 shows the spreadsheet used to calculate the LUT values.

IMS Look of Table Calculation					
	Vref, (V) =		2.560	Dir Coupler Factor (dB) =	50.00

1023	2.558	22.3	72.3	16982.4365246	1698244

Table 8 - IMS Power Look Up Table Calculation

The AD8307 V_{out} is calculated for each possible ADC value from 0-1023 using equation (16).

$$V_{out} = V_{REF}\left[\frac{ADC}{1024}\right] \qquad (16)$$

AD8307 input power, P_{IN}, in dBm, is calculated using equation (17).

$$P_{IN}, dBm = \frac{V_{out} - [AD8307\ Y - int, (V)]}{\left[AD8307\ Slope, (\frac{V}{dB})\right]} = \frac{V_{out} - 2V}{\left[0.025\ (\frac{V}{dB})\right]} \qquad (17)$$

The directional coupler input power is calculated by adding the 50 dB coupling factor to the AD8307 input power.

The directional coupler input power is converted to W using equation (7). The ATmega32 microcontroller cannot perform the equation (7) exponential function since it requires a floating point operation. This necessitates the LUT.

The LUT contains pre-calculated results of the equation (7), (16), and (17) math functions. The LUT shares 32 kB memory with the 8 kB software program limiting its size to 24 kB or 1536 values at 16 bits each. 16 bit values can represent integers up to 2^{16} or 65,536. Since the microcontroller cannot work with fractional numbers, they must be converted to whole integer numbers by multiplying up to larger value numbers, performing the required calculations, and then using integer division to obtain the final result. This method preserves some of the accuracy that would otherwise be lost if all numbers were rounded to whole numbers.

All digital systems have accuracy limitations since values between consecutive binary values cannot be defined. In contrast, analog systems can process an infinite number of values. For example, if a 10 bit digital system must represent a voltage range from 0 to 1 V, it can only represent 210 or 1024 possible values between 0 and 1 V. In an analog system, the voltage can assume an infinite number of possible values between 0 and 1 V. The designer must use a system with enough bits to ensure the required accuracy.

The IMS minimum power measurement required is 10 mW or 10 dBm. At the lowest IMS RF input power of 3 W, 10 mW reflected power gives 1.12 SWR using equation (2). If the minimum measurable power is limited to 10 mW, the IMS could attain a minimum SWR of 1.12, which is less than the IMS matching capability requirement 1.5 SWR or less.

Since the IMS maximum power requirement is 100 W, its power measurement ability must be greater than 100 W. A maximum of 200 W was arbitrarily chosen. Therefore, the total required measurement range is 10 mW – 200 W or 10 dBm to 53 dBm. From Table 8, the power values are in 0.1 dB steps. With a 43 dB measurement range, the required LUT size is 430 values. With a start value of 0.01 W, the LUT values must be multiplied by 100 to convert all values to integers. The system divides the values by 100 to get the power in W prior to displaying on the LCD.

From equation (14), -80 dBm corresponds to 0 V power sensor output. With the IMS power measurement range limited from 10 dBm to 53 dBm, the first LUT value corresponds to 10 dBm. From equations (16) and (17), the corresponding ADC value is 400. The LUT is written in a C programming structure called an array, which is a programmable number of memory locations storing the same data type under the same variable name. Array values are accessed by inserting a reference number in brackets following the array name. For the array named "Power_LUT", the program accesses the first value using "Power_LUT[0]." With the LUT size set to 430, the last value is accessed using "Power_LUT[429]." The IMS LUT table converts ADC values to power in W. The LUT begins at an ADC value of 400. The ADC results are stored in a variable named "power_index," which then has 400 subtracted from it. It is then used to select values in the LUT. ADC values below 400 are set to zero; therefore the IMS registers power below 10mW as 0W. The following code shows how the LUT power value is assigned in the C program. Comments in green explain each line of code.

```
Power_index = ADC;          // store ADC converted value to Power_index variable
   if (Power_index < 400)   // this makes any power less than offset = 0 W
       Power_index = 0;
   else
       Power_index = Power_index - 400;   // index of proper value in LUT
       Forward_Power = Power_LUT[Power_index]; //store power to Forward_Power variable
```

The IMS power meter can be calibrated in software. If the measured power is a constant dB value off from the actual power over the full measurement range, the 400 offset value can be changed to reference offset power values in the LUT. Since each consecutive LUT value is a 0.1 dB change, the dB adjustment value required for calibration multiplied by 10 is the required offset change. For example, if the indicated power is 50W when the actual power is 100W, a 3 dB difference, then the 400 offset must be changed by 30. Changing the offset number from 400 to 370 corrects the 3 dB error by referencing 3 dB higher values in the LUT.

If the power measurement error is not a consistent dB value, there is a slope error. For example, the power is 3 dB off at 10 W and 6 dB off at 100 W. This error requires recalculating the LUT using a different slope in equation (17).

Automatic Impedance Matching

To develop the IMS automatic impedance matching ability, three algorithms were written and tested

First algorithm:

1. For RF input power 5 W or greater, begin automatic tuning when Tune button is depressed
2. Measure and record current SWR
3. Rotate inductor one step in increasing direction
4. If SWR decreased, repeat 2.
5. If SWR increased, rotate inductor one step in decreasing direction
6. If SWR decreased, further decrease inductance

7. When SWR minimum is determined, repeat 1 through 5 for the capacitor.
8. If SWR is greater than 1.5:1, repeat for the inductor and then capacitor up to 3 times.
9. Stop automatic tuning attempt if the Tune Button is pressed again or if RF input power falls below 5 W.

This first algorithm adjusts inductance and capacitance based on SWR increase or decrease. This approach assumes that inductor or capacitor value variations in one direction consistently increase or decrease the SWR until the minimum is reached. This may hold true for an average over several SWR samples. In actuality, due to measurement noise or random fluctuation, the SWR may increase for small adjustments even if the adjustments are in the correct direction to achieve an impedance match.

A second algorithm was written using a different approach as follows:

1. Measure and store current SWR as minimum SWR.
2. Set the inductor motor direction to increase inductance.
3. Change inductance by one motor step
4. Measure SWR.
5. If the new SWR is less than the stored minimum value, store the new value as the minimum SWR and store the inductor position.
6. If the SWR increased, increment a counter tracking the number of times the SWR increased.
7. Repeat Steps 3 through 6 until the number of steps for which the SWR increased exceeds a set value (increasing SWR step count, optimum value determined through trial and error). Change the motor direction to decrease inductance.
8. Repeat Steps 3 through 6 after the Step 7 direction change until the increment counter exceeds the set value (increasing SWR step count, optimum value determined through trial and error).
9. Return the inductor to the minimum SWR position.
10. Repeat Steps 1 through 9 for the capacitor.
11. Repeat Steps 1 through 10 up to 4 times or until the SWR decreases below 1.5.
12. If the SWR is still greater than 1.5, stop the tuning process.

This algorithm failed as it would only attain an impedance match if the required inductor and capacitor positions were within the set number of increasing SWR steps. Setting the increasing SWR step count to higher values, from 20 to 200, improved match success rate. However, the full range is 1660 steps for capacitance and 3500 steps for inductance. These full ranges must be searched to find the optimum match values. The inductor has a full range of 8500 steps, however for all loads tested, the inductor never required a setting beyond 3500. Therefore, the inductance search range was set to 0-3500.

A third and final algorithm was written:

1. Set the inductor to minimum inductance position and the capacitor to maximum capacitance position.

2. Measure and store current SWR as minimum SWR.
3. Increment the inductor from minimum to maximum value. For each motor step:
    a. Measure SWR.
    b. If the new SWR is less than the stored minimum value, store the new value as the minimum SWR and store the inductor position.
4. Once the maximum inductance is reached, return the inductor to the location of minimum SWR.
5. Repeat steps 2 through 4 for the capacitor, stepping from maximum to minimum capacitance.
6. If the SWR is still greater than 1.5, perform Steps 7 through 17.
7. Measure and store current SWR as minimum SWR.
8. Set the motor direction to increase inductance.
9. Change inductance by one motor increment.
10. Measure SWR.
11. If the new SWR is less than the stored minimum value, store the new value as the minimum SWR and store the inductor position.
12. If the SWR increased, increment a counter tracking the number of times the SWR increased.
13. Repeat Steps 9 through 12 until the number of increments for which the SWR increased exceeds a set value. Change the motor direction to decrease inductance.
14. Repeat Steps 3 through 6 after the direction change in Step 13 until the increasing SWR increment counter exceeds the set value (increasing SWR step count, optimum value determined through trial and error).
15. Return the inductor to the minimum SWR position.
16. Repeat Steps 7 through 15 for the capacitor.
17. Repeat Steps 7 through 16 up to four times or until the SWR decreases below 1.5.
18. If SWR is not below 1.5, stop the tuning process.

Steps 1 through 5 perform low resolution (coarse) tuning and Steps 7 through 17 perform fine tuning.

Optimum settings determined through trial and error:

Inductor step angle: 1.8°/step, or 200 steps/revolution
Capacitor step angle: 0.1125°/step, or 3200 steps/ revolution
Inductor increasing SWR step count: 110
Capacitor increasing SWR step count: 250
Inductor coarse tuning step time interval: 2 ms
Capacitor coarse tuning step time interval: 10 ms
Inductor fine tuning step time interval: 13 ms
Capacitor fine tuning step time interval: 10 ms

Chapter 7. Integration and Test Results

1. Directional Coupler

The following equipment was used for directional coupler testing:

- Vector Network Analyzer, HP8753A
- Spectrum Analyzer, Agilent N9000A
- RF Signal Generator, Fluke 6060B
- Attenuator, Coaxial 20±0.2 dB fixed, 50 Ω, 0.5 W, DC – 2 GHz, Mini-Circuits HAT-20+, Quantity: 2
- 50 Ω termination, Anritsu

Test 1: RF Input Port S11

The first test performed was input port S11 measurement to ensure that the directional coupler would not present high standing wave ratio (SWR) values to a connected transmitter. The directional coupler input SWR was measured using the Figure 25 setup.

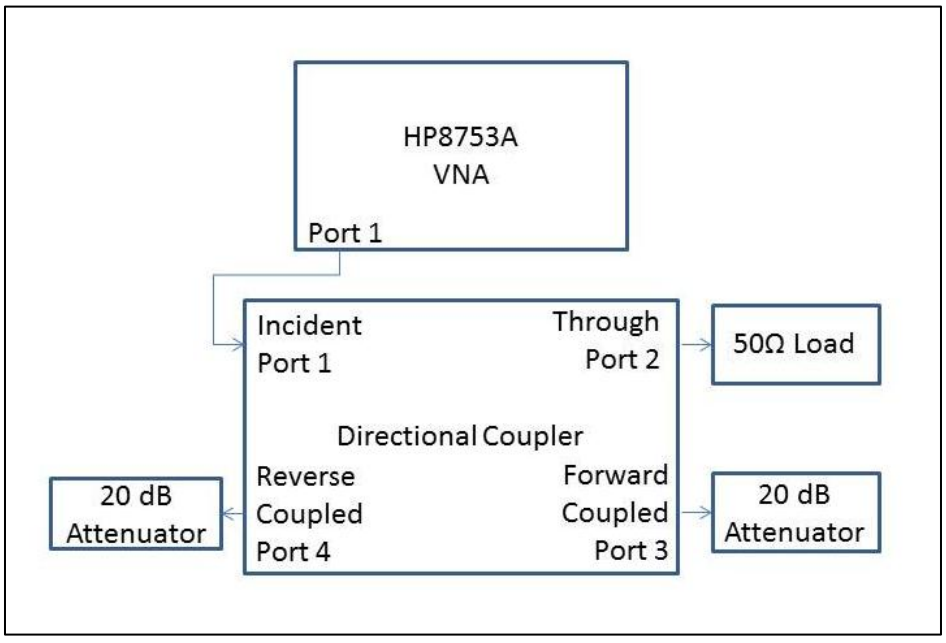

Figure 25 - Directional Coupler SWR Test Setup

The 20 dB attenuators served as 50 Ω terminations.

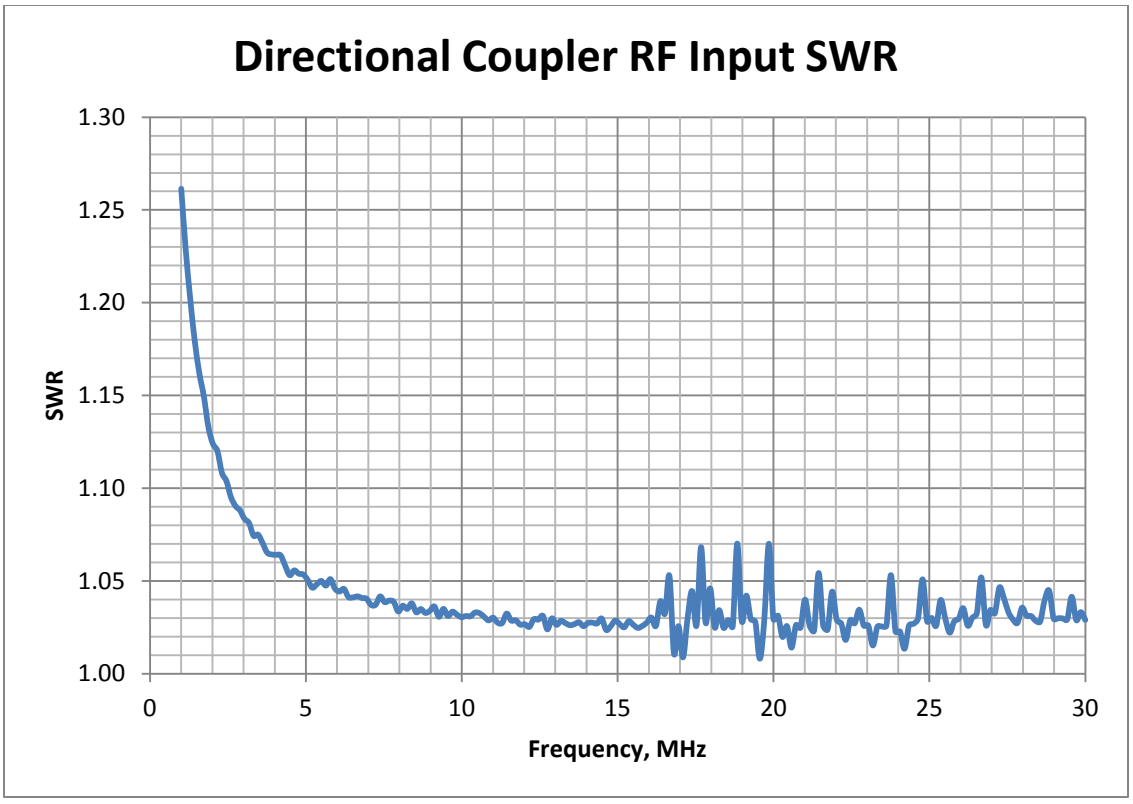

Figure 26 - Directional Coupler RF Input Port SWR

Figure 26 shows the RF input port SWR measured using the VNA. The worst case SWR for 3.5-30 MHz is 1.07 at 3.5 MHz. The directional coupler SWR must be less than 1.5 for the IMS to meet its matching requirement of 1.5 SWR or less.

Test 2: Coupling Factor

The forward coupling factor is the dB difference between the power measured (dBm) at the incident (RF input) port and forward coupled port. This was measured using the Figure 27 setup.

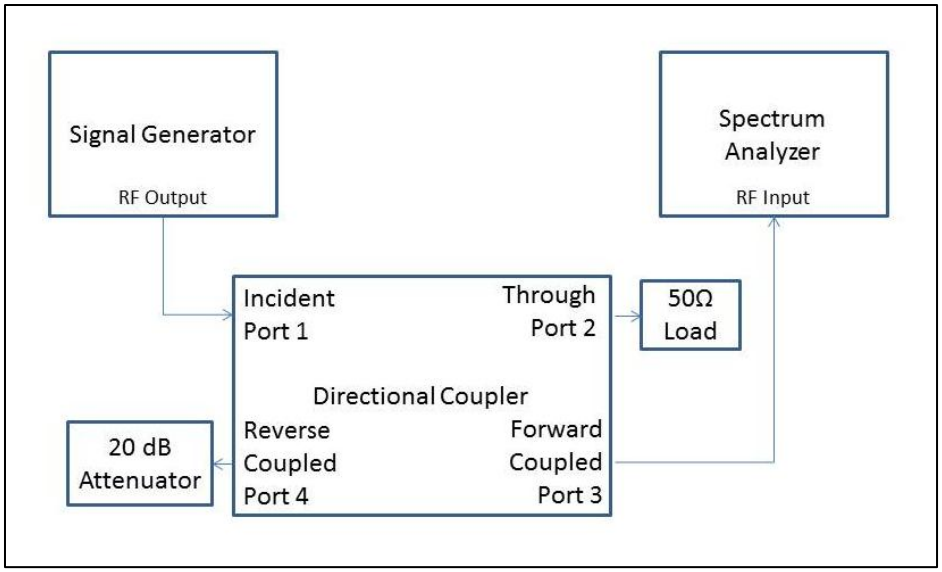

Figure 27 - Forward Coupling Factor Test Setup

The spectrum analyzer was set for 1 – 31 MHz span and placed in "max hold" mode. The signal generator was set to 0 dBm and the frequency was swept from 1 – 31 MHz. The spectrum analyzer "max hold" mode captured the power measured from the forward coupled port. With the signal generator set to 0 dBm, equation (18) yields coupling factor.

$$coupling\ factor, (dB) = 0\ dBm - measured\ power, (\ dBm) \qquad (18)$$

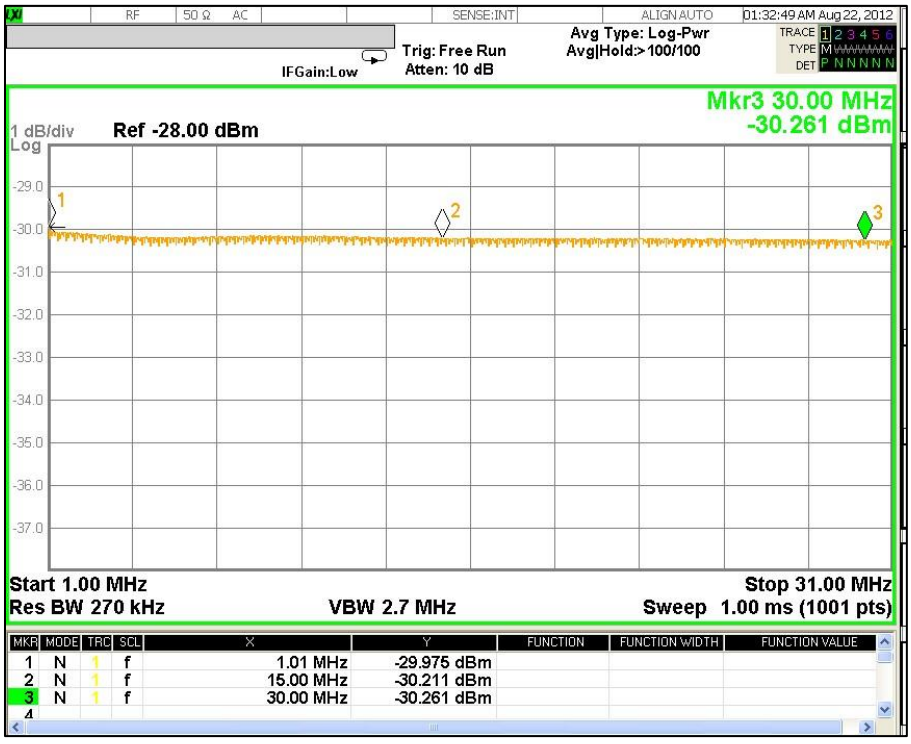

Figure 28 - Directional Coupler Forward Coupling Factor

Figure 28 shows the spectrum analyzer forward coupling factor measurement. The forward coupling factor is approximately 30 dB and varies by less than 0.5 dB from 1 – 31 MHz. This is the expected result per Kaune [11].

The reflected coupling factor is the dB difference between through port and reverse (reflected) coupled port power. This was measured using the setup shown in Figure 29 using the same procedure for the forward coupling factor measurement.

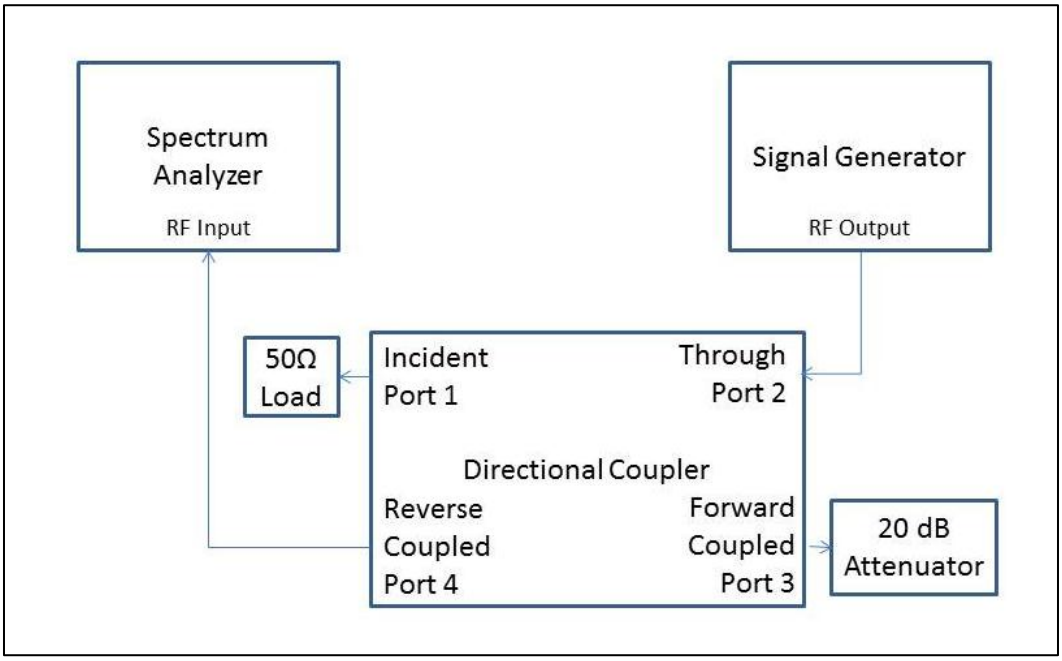

Figure 29 - Reverse Coupling Factor Test Setup

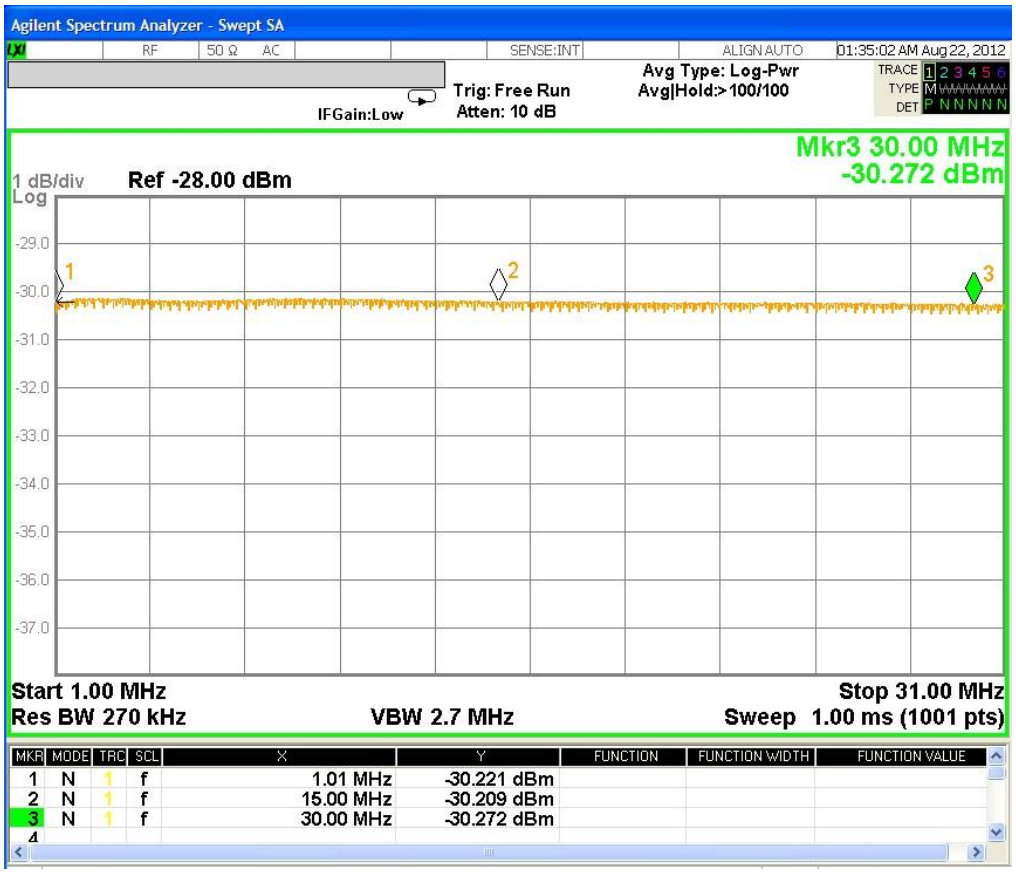

Figure 30 - Directional Coupler Reverse Coupling Factor

Figure 30 shows the spectrum analyzer reverse coupling factor measurement. The reverse coupling factor is approximately 30 dB and varies by less than 0.5 dB from 1 – 31 MHz. This is the expected result per Kaune [11].

Test 3 – Directivity

The directional coupler directivity is the dB difference between forward and reflected coupled powers with power applied at the incident port and the through port terminated in 50 Ω. The reverse coupled port power with power applied at the incident port was measured using the Figure 31 setup. The signal generator was again set to 0 dBm and swept from 1 – 31 MHz.

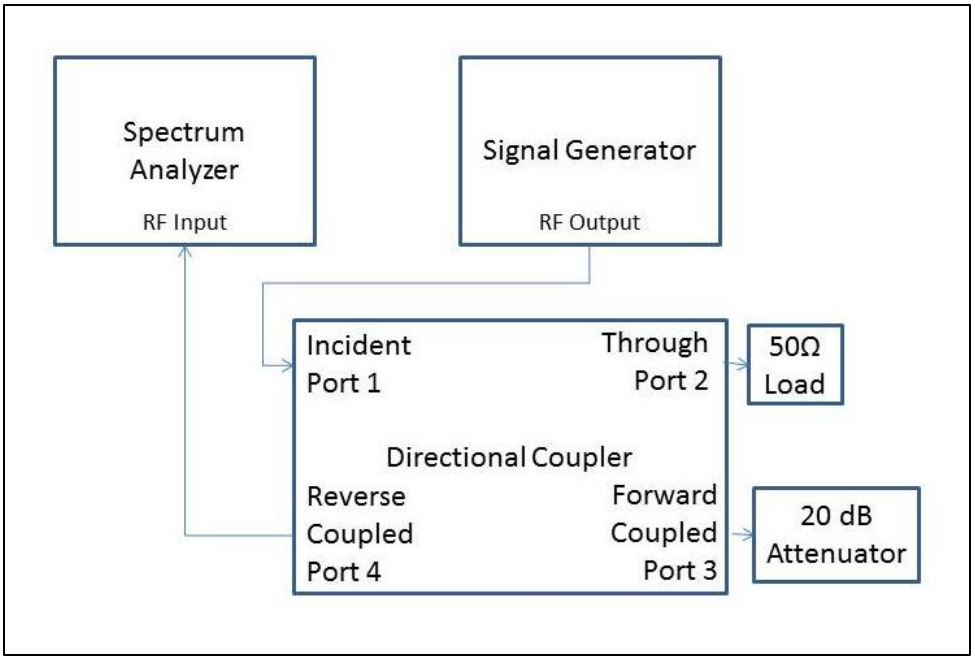

Figure 31 - Directional Coupler Directivity Test Setup

The directivity was calculated by subtracting the Figure 31reverse port power measurement from the forward port power measurement. The resulting directivity is plotted in Figure 32.

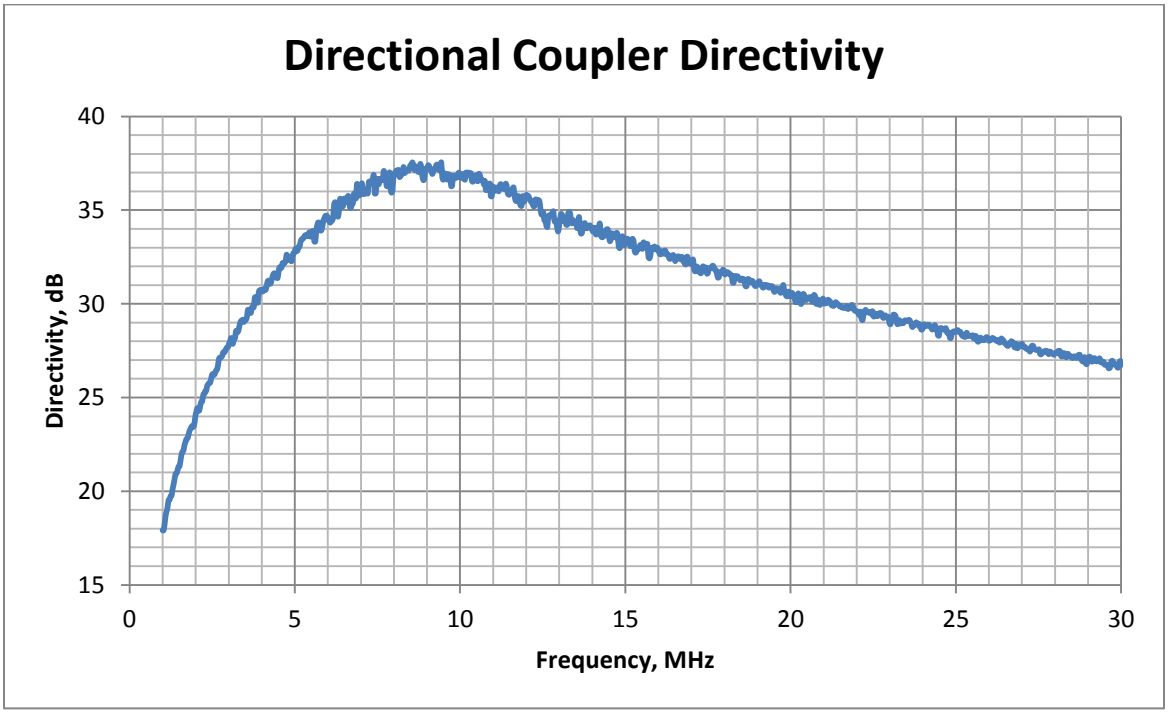

Figure 32 - Directional Coupler Directivity

The worst case directivity for 3.5 – 30 MHz is 26.56 dB at 29.65 MHz. Kaune claimed a worst case directivity of 28 dB [11]. Directivity is ideally infinite.

For 100 W (50 dBm) forward power and 30 dB coupling factor, the forward coupled power is 20 dBm or 0.1 W. With 28 dB of directivity, the reflected coupled port power is:

$$20 \text{ dBm} - 26.56 \text{ dB} = -6.56 \text{ dBm} = 0.22 \text{ mW} \qquad (19)$$

Using equation (2) to calculate SWR from forward and reflected coupled power, the SWR measured using this directional coupler is 1.1.

The IMS power measurement limit is determined as follows:

Given:
Directional coupler coupling factor = 30 dB
Maximum RF power sensor input power = 17 dBm
Maximum Directional Coupler Input Power = 17 dBm + 30 dB = 47 dBm (50 W) (20)

Add 20 dB , 0.5 W (27 dBm), attenuators at forward and reflected coupled ports:
Maximum Directional Coupler Input Power = 27 dBm + 30 dB = 57 dBm (500 W) (21)
RF sensor input power at 500W = 57 dBm – 20 dB – 30 dB = 7 dBm (22)

The IMS maximum RF power requirement is 100 W.

2. RF Power Sensor

The forward and reflected RF power sensors were tested for DC voltage output linearly proportional to RF power input using the test setup shown in Figure 33.

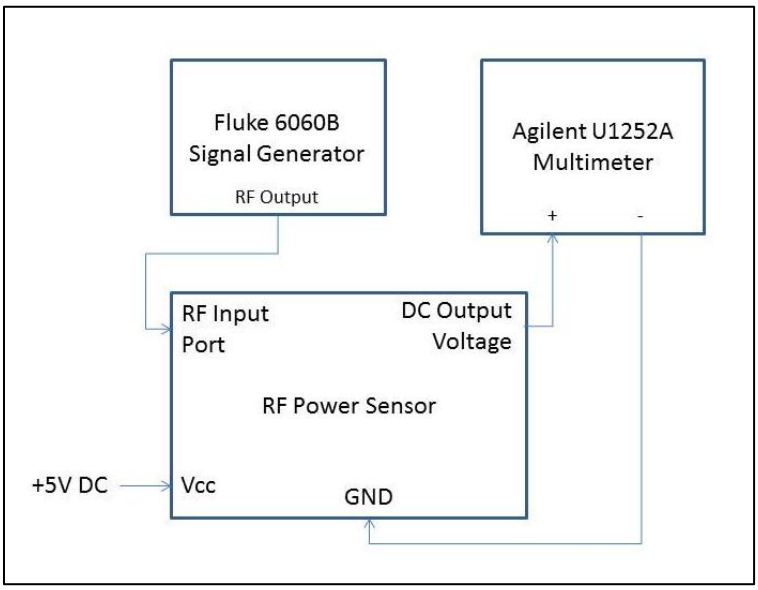

Figure 33 - RF Power Sensor Test Setup

The AD8307 datasheet [10] specifies a measurement capability of -75 dBm to +17 dBm. The sensors were tested in this range, but the voltage output was non-linear below -50 dBm as shown in Figure 34. The Fluke 6060B signal generator maximum output power is 13 dBm.

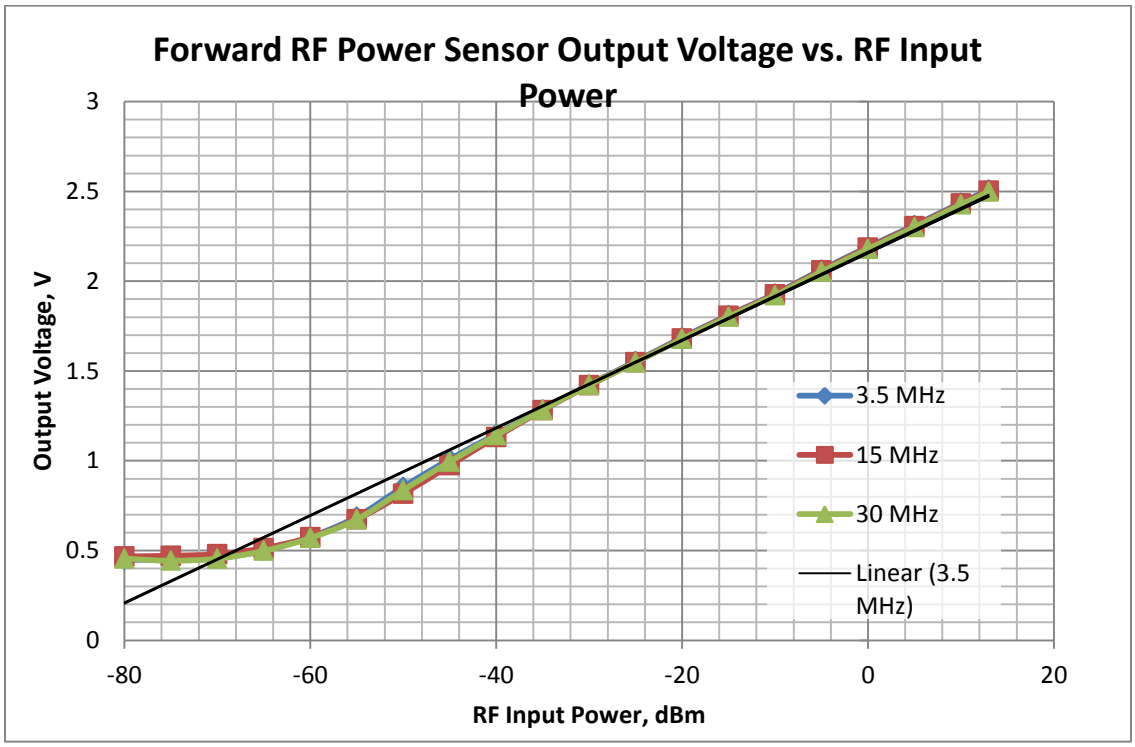

Figure 34 - Forward RF Power Sensor Output Voltage vs. Input Power, -80 to 13 dBm

The IMS minimum power measurement is 10 mW. At minimum IMS RF input power of 3 W, 10 mW reflected power yields 1.12 SWR using equation (2). If the minimum measurable power is limited to 10 mW, the IMS could calculate a minimum SWR of 1.12, which is less than the IMS matching requirement of 1.5 SWR or less.

For 10 mW (10 dBm) reflected power, RF power sensor input is -40 dBm after 30 dB directional coupler coupling factor and 20 dB attenuator. Therefore, the minimum RF sensor measurement is -40 dBm.

The power sensors were tested from -40 dBm to +13 dBm at 3.5, 15, and 30 MHz. Figure 35 and Figure 36 show forward and reflected power sensor output voltage responses, respectively.

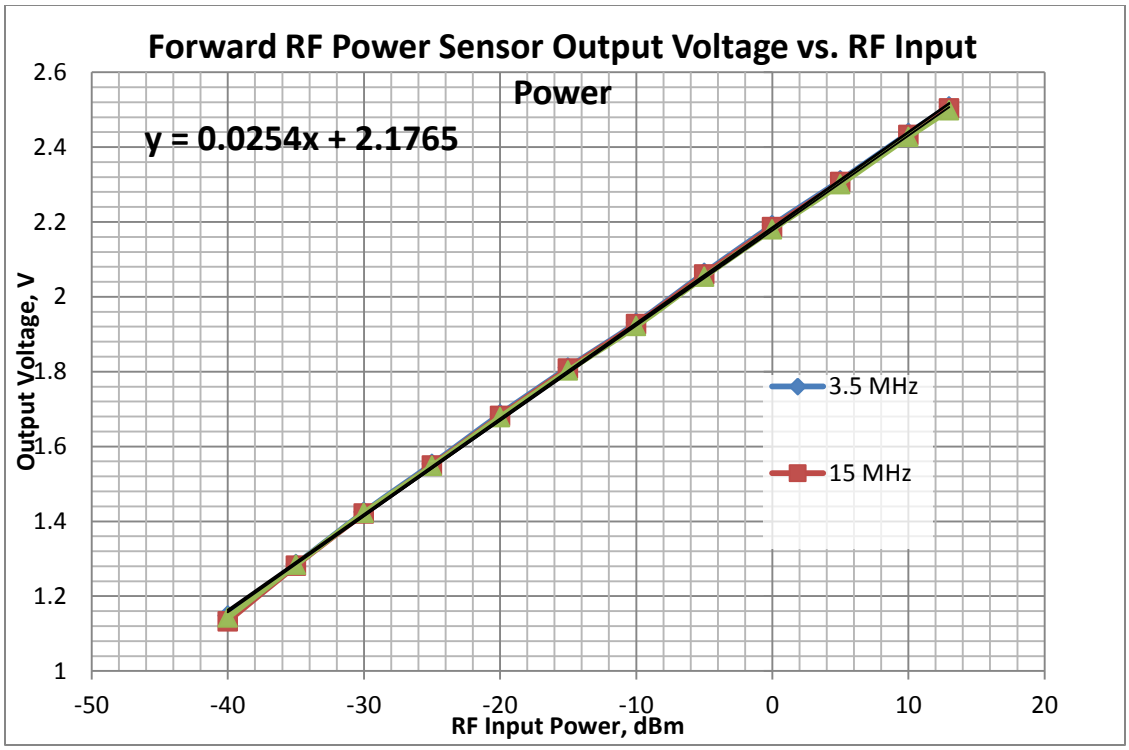

Figure 35 - Forward RF Power Sensor Output Voltage vs. Input Power, -40 to 13 dBm

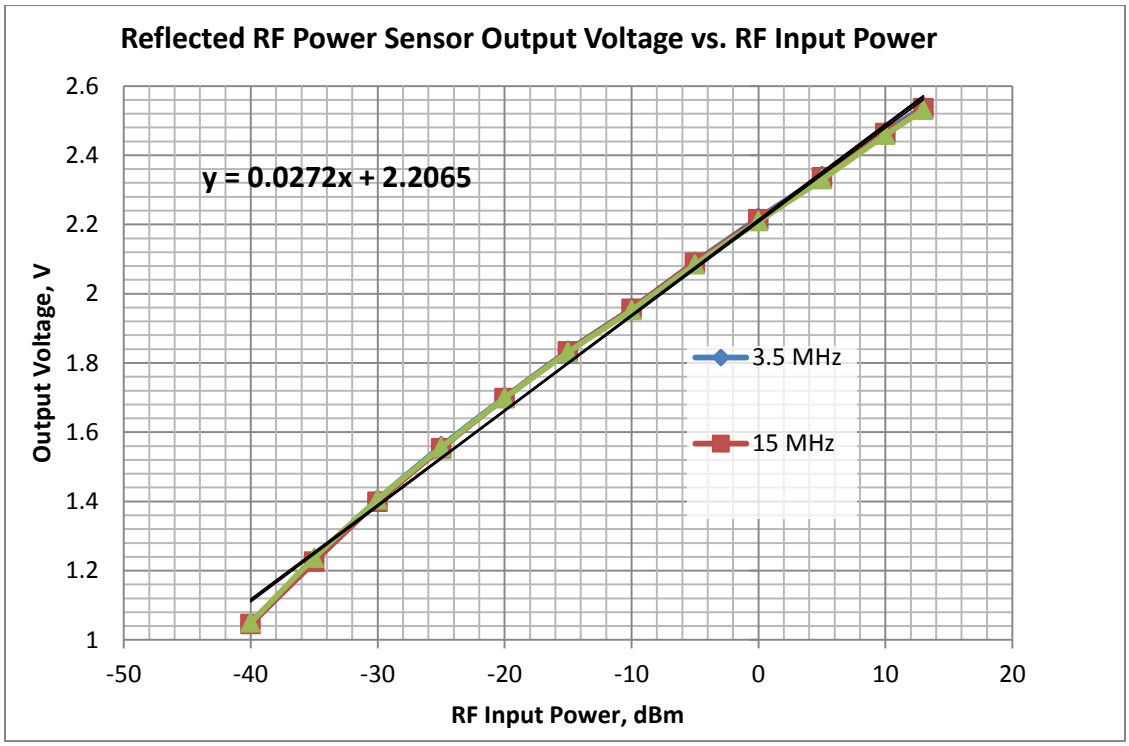

Figure 36 - Reflected RF Power Sensor Output Voltage vs. Input Power, -40 to 13 dBm

The curve-fit equations shown in Figure 35 and Figure 36 are linear fit relations for the data. The equation slope is the AD8307 datasheet parameter "Logarithmic Slope" in units of V/dB. The measured forward and reflected slopes are 25.4 mV/dB and 27.2 mV/dB, respectively. The datasheet specifies 23 – 27 mV/dB from -75 dBm to + 17 dBm. The equation Y-intercept should be 1.9 – 2.2 V [10].

3. Power Supply

Table 9 shows the power supply voltages tested as specified in the Chapter 6 Test Plan.

DC Power Supply Test Data				
	Output Voltage, V			
	No Load	Full Load	Design Requirement	Datasheet Specification [16] [17]
5 V, 0.5 A DC Supply	5.031	5.028	4.7 to 5.5	5±0.05
12 V, 1 A DC Supply	12. 07	11.94	11 to 13	12±0.6

Table 9 - DC Power Supply Test Data

The supply voltages were measured at the microcontroller module power connectors with applied system power. With all stepper motors off, the 12 V and 5 V supplies measured 12.070 V and 5.028 V, respectively. With the inductor motor on, the 12 V and 5 V supplies measured 11.940 V and 5.028 V, respectively. These voltages are still within the datasheet specifications for the 5 V and 12 V regulators [16] [17].

4. Stepper Motors

Figure 37 shows the stepper motor test setup. This test determined whether the motor produces the torque required for variable inductor and capacitor rotation. Since the motor successfully rotated the capacitor and inductor, the required torque was less than the maximum rated motor torque of 125 oz-inch. A method to measure the actual required torque was not available.

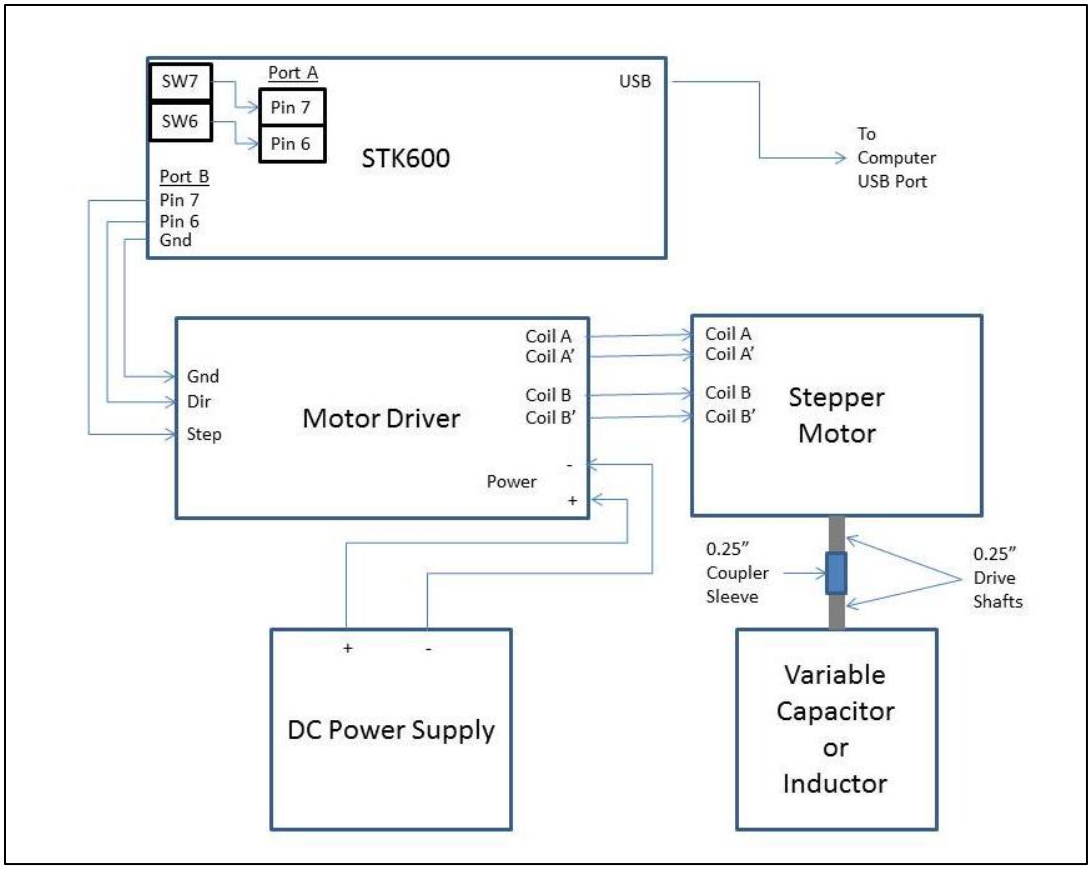

Figure 37 - Stepper Motor Test Setup Block Diagram

The STK600 Development board provides power, clock signal, and programming interfaces to the microcontroller. It also provides large pin breakouts for all input and output ports allowing solderless connections.

The stepper motor driver provides the required power waveforms to the stepper motor. The two motor coils, A and B, must be driven by 90° out of phase square waves. The motor drive waveforms rotate the motor one step for each rising edge, 0 V to 5 V, of a digital signal applied to the STEP input. This simplifies the microcontroller program used to control the stepper motor. The DIR input controls rotational direction; high (5 V), counterclockwise, low (0 V), clockwise. [20]

Stepper motor specifications give motor current for a specified voltage. The IMS motors are rated for 2 A 3 V DC [18]. The motor can function with higher voltage at a proportionally lower current (V*I = 6 W maximum). For the test, the voltage was set to 12 V, requiring 0.5 A.

When power is applied to the driver, the motor draws the same current regardless of whether it is moving or stationary. This maintains mechanical loads that rotate away from the required position. Since the variable capacitors and inductors remain stationary due to static friction, the motors can be powered down when no adjustments are required, saving power. The initial lack of clarity on this stepper motor aspect caused some confusion as to whether there was a driver malfunction or incorrect driver to motor wiring.

Figure 38 shows the capacitor stepper motor test setup. The motor was mounted using a makeshift setup for testing purposes. A permanent mounting fixture was fabricated for installation in the antenna tuner. The capacitor's full value range is spanned in a half revolution. At the top motor speed tested, the capacitor is actuated through its full range in less than one second.

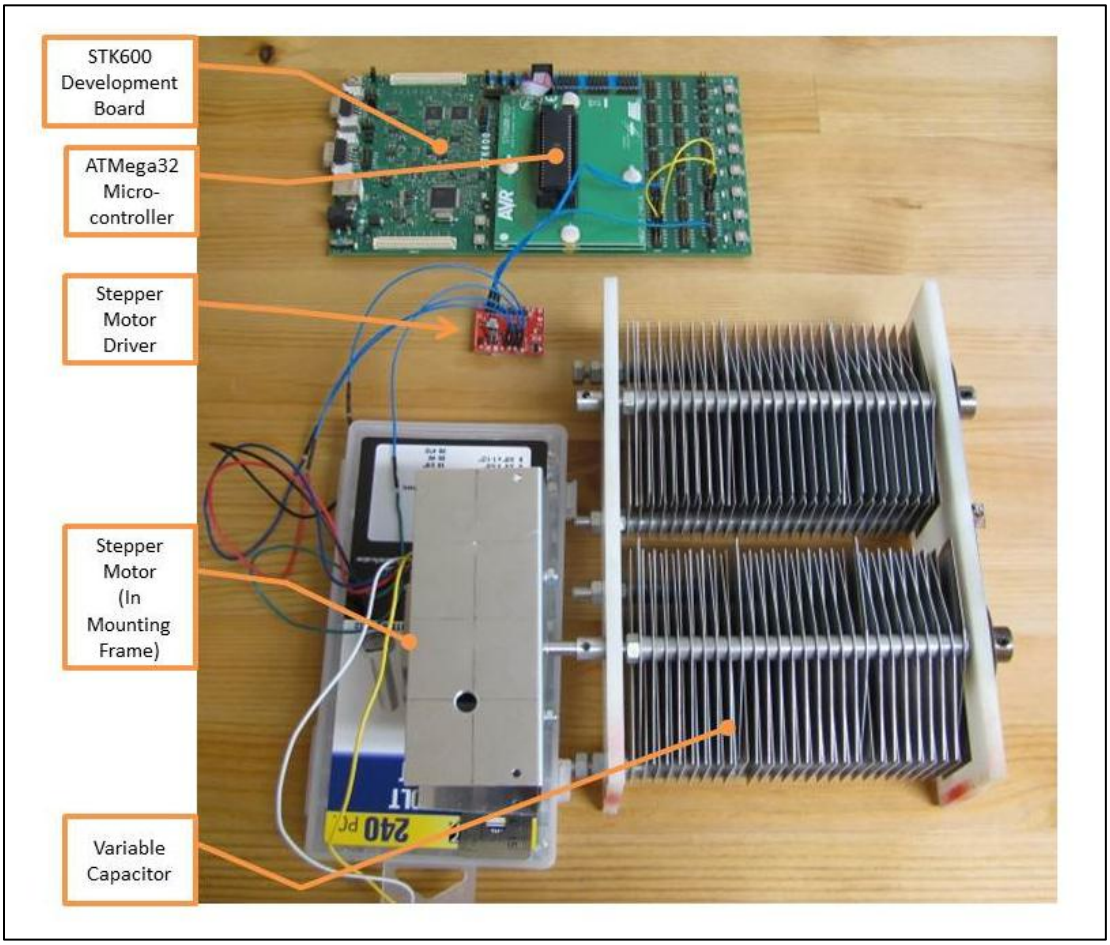

Figure 38 - Capacitor Stepper Motor Test Setup

In Figure 38, the motor driver DC power supply leads and the STK600 USB cable are not yet connected. Two variable capacitors are attached to a common frame. Only one is required for the IMS.

The stepper motor is unipolar; each coil has three leads: two outer leads and a center tap. The motor is unipolar because the power supply current does not change polarity. Positive supply voltage is connected to the center tap and the driver grounds either outer lead depending on the required winding field direction. [23] Bipolar motors have two leads for each coil. The driver reverses coil voltage polarity to change the field direction. The motor driver, while designed for bipolar motors, can drive unipolar motors if the center tap leads are not connected. [20] Figure 39 shows the unconnected white and yellow center tap motor leads.

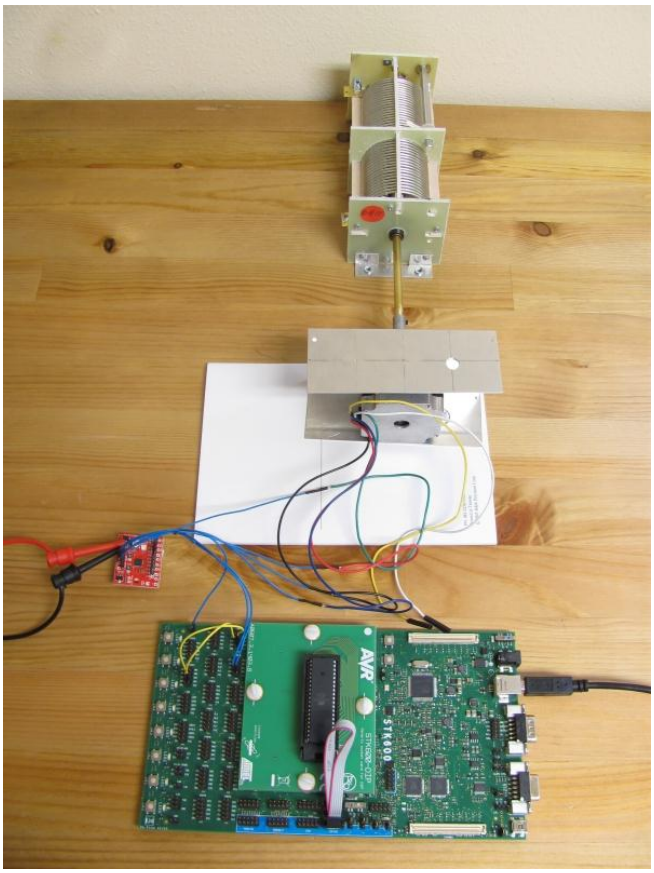

Figure 39 – Variable Inductor Motor Test Setup

Figure 39 shows the variable inductor drive test configuration. At the maximum motor speed setting, the inductor travels through its full range in approximately 20 seconds. Full range traversal requires 43 shaft revolutions.

Figure 40 – C program for stepper motor testing

Figure 40 shows the C program written for microcontroller motor testing. Comments in blue text explain the function of each line. Basic functions include motor rotation using one button (or momentary switch) and rotation direction selection using a second button. Two IF statements accomplish these two functions. The first IF statement steps the motor continuously when Button 7 is pressed. The "_delay_us(x)" function defines a software delay of x microseconds. The delays in the first IF statement set the motor speed. Increasing the delay decreases motor speed. The second IF statement changes the motor direction each time Button 6 is depressed. The button numbers are labeled on the STK600.

Since the motor can drive the capacitor and inductor directly, gear reduction is not required. The inductor drive speed rotates the antenna tuner at slower rates than relay selected fixed inductor designs. Turning the inductor faster may increase wear, decreasing component life.

5. IMS Power Meter

The Impedance Matching System (IMS) requires power measurements and SWR calculation to achieve an impedance match. Uncalibrated, the IMS indicated 2:1 SWR for a matched load.

Calibration requires comparison to measurement devices of known accuracy. The most accurate power meter available is the Agilent N9000A Signal Analyzer, with specified amplitude accuracy of ±0.5 dB [24]. Its +30 dBm maximum input power limits usefulness for calibrating a 100 W (50 dBm) power meter. A 30 W, 30 dB attenuator allows power measurements to +44.8 dBm (30 W). Since power levels greater than 30 W could damage the attenuator and the N9000A, a different power meter was required for 30 W to 100 W calibration.

Three wattmeters with 100 W ratings or greater are available: A Bird 43 analog wattmeter with a 2 MHz -30 MHz, 250 W element; a Motorola R22 0.1 to 1000 MHz Communications Service Monitor (measures up to 100 W); and a Daiwa CN-801 1.8 to 200 MHz, 2000 W analog wattmeter. These wattmeters were compared to the Agilent N9000A spectrum analyzer in power measurements up to 30 W in Table 10. The 30 dB attenuator was connected to the N9000A RF input for protection.

Table 10 - Power Meter Comparison

The Bird wattmeter was the most accurate with a maximum 0.8 dB difference from the N9000A. This unit was used for power calibration from 30 W to 100 W.

The IMS power meter was calibrated using the setup shown in Figure 41 for 0 W to 30 W calibration and Figure 42 for 30 W to 100 W calibration. To calibrate the reflected power measurement, the directional coupler RF input and output ports were interchanged; RF power was applied to the output port.

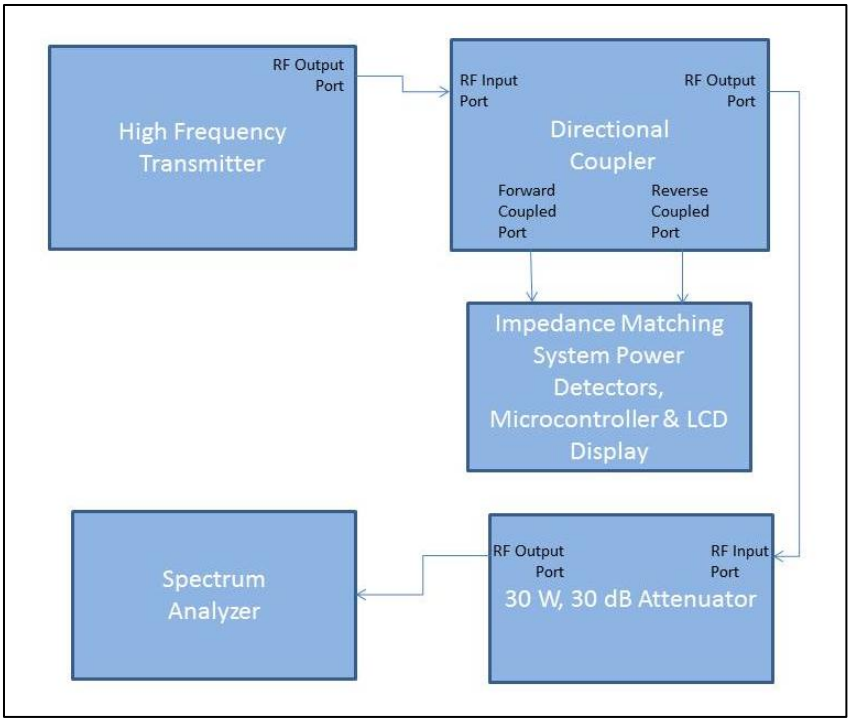

Figure 41 - IMS 0 W to 30 W Power Calibration Setup

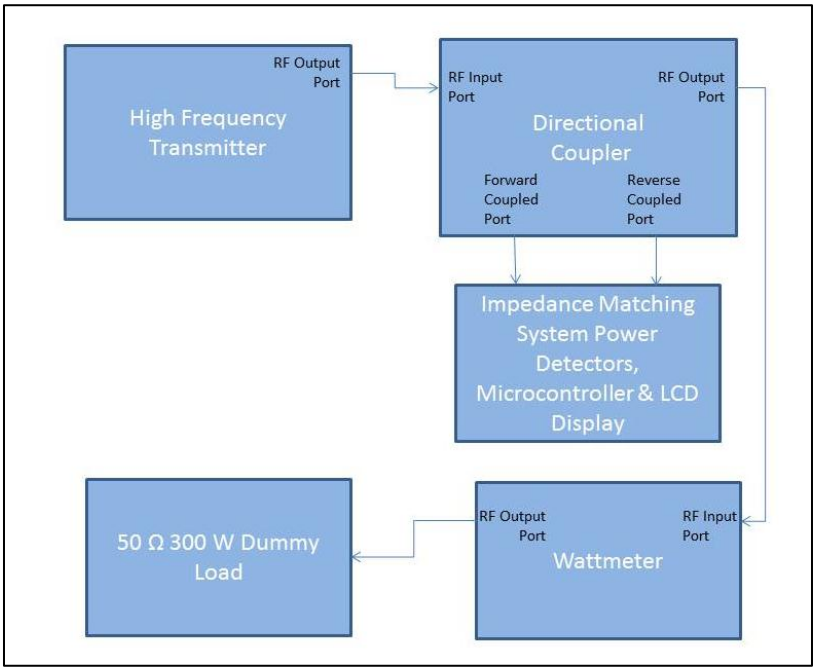

Figure 42 - 30 W to 100 W Power Calibration Setup using Bird 43 Wattmeter

Initially, the IMS forward power indication averaged 2.5 dB less than spectrum analyzer measurements. Since each consecutive value in the IMS LUT represents a 0.1 dB power increment, an offset number of 25 (25 * 0.1 dB = 2.5 dB) was added to the "power_index" variable in the C program as described in Chapter 6. The IMS reflected power was an average of 3.6 dB less than SA values; an offset of +36 was used.

After comparing the IMS power meter to the SA, it was compared to the Bird wattmeter. The Bird wattmeter scale increments are 5 W for the 250 W element. Estimating the halfway point between increments allows ±2.5 W measurement certainty. Therefore, the IMS power meter displays values within ±2.5 W of the Bird wattmeter.

Table 11 and Table 12 show power measured by the Agilent N9000A spectrum analyzer (SA) compared to IMS measured power after calibration. The SA measured power was adjusted by 30 dB to account for the 30 dB attenuator. Since the IMS can only display whole number power values, due to LCD character limit, the values in the IMS measured power column are shown to zero decimal places. As Tables 10 and 11 show, the IMS power is a maximum of 0.66 dB off from the SA measurement.

Forward Power

6. Matching Network

To test automatic matching ability, a test of five trials was conducted for 8 different frequencies using the following settings:

The test was performed using a 50 Ω resistive dummy load and 4:1 balun at the impedance matching system antenna connector. Figure 43 shows S11 for the dummy load and balun combination from 10 MHz to 30 MHz.

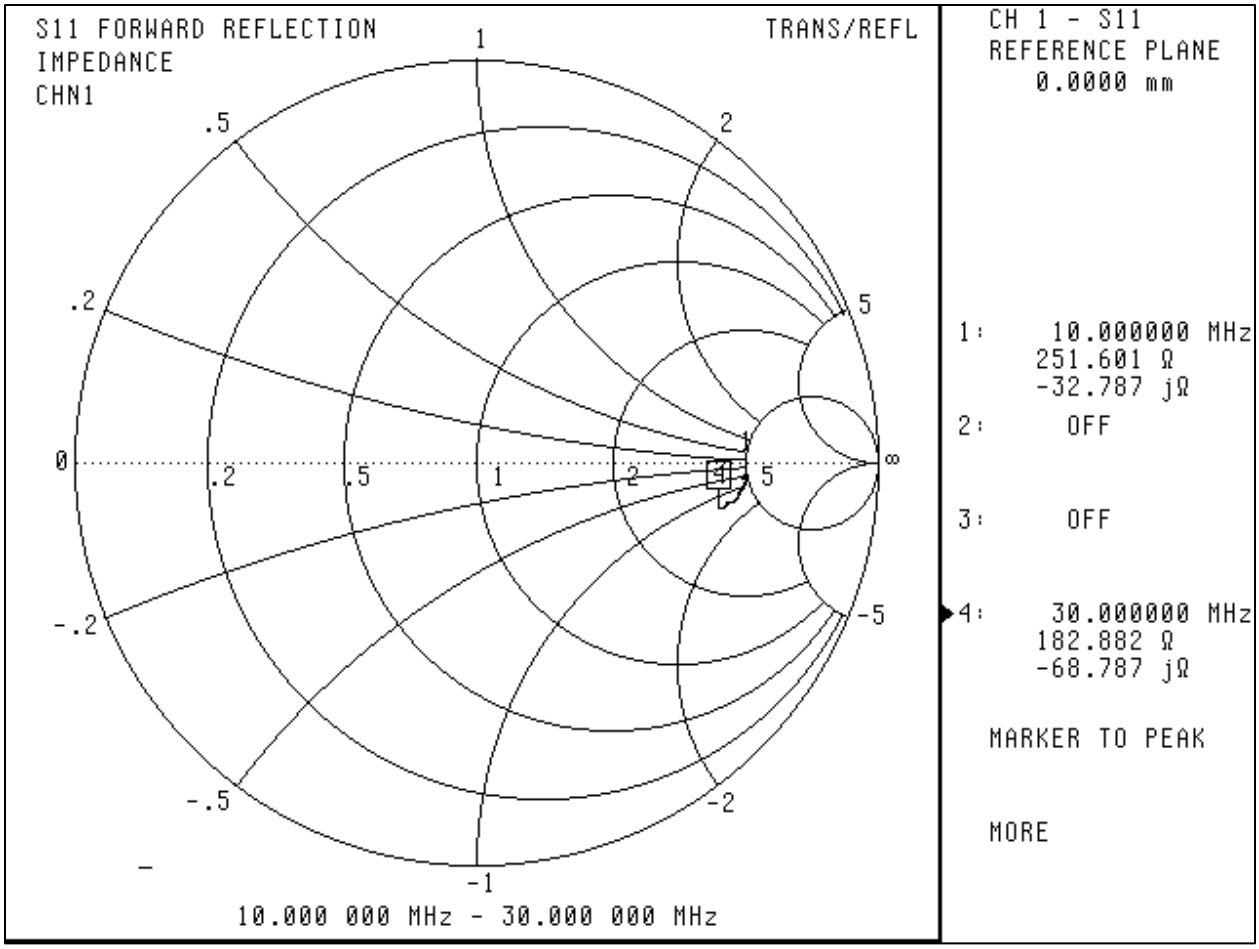

Figure 43 - S11 for 50 Ω load and 4:1 Balun.

Table 14 shows results for all test trials. The transmitter power was set at 10 W. SWR was measured using the IMS internal SWR meter.

	SWR results for IMS Dummy Load Matching Ability				
Frequency, MHz	Trial 1	Trial 2	Trial 3	Trial 4	Trial 5
3.500	1.46	1.35	1.40	1.40	1.46
7.100	1.04	1.04	1.43	1.29	1.15

28.850	1.19	1.19	1.24	1.32	1.24

Table 14 - Results of IMS match testing into dummy load

As shown in Table 14, the system provided SWR values of less than 1.5:1 for 100% of the trials at all frequencies.

The IMS was then tested for dipole antenna matching ability. The dipole used for testing utilizes the Cal Poly Amateur Radio Club antenna tower for the dipole center support approximately

40 ft above ground. The dipole ends are tied off using nylon rope to points on the EE building roof and are approximately 25 ft above the ground. Figure 44 shows the dipole location.

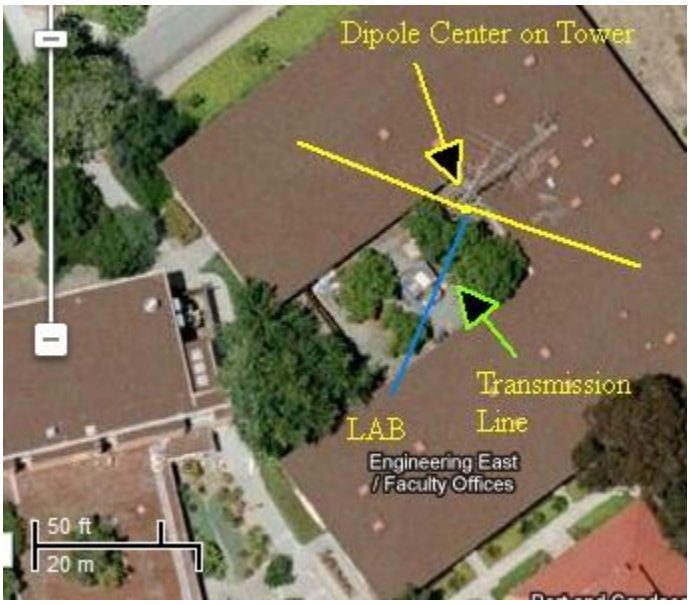

Figure 44 - Dipole Antenna Location

The dipole is connected to the IMS using 90 ft of 450 Ω balanced transmission line. Balanced transmission line is available with 300 Ω, 450 Ω, and 600 Ω characteristic impedance and 450 Ω line was an arbitrary choice.

The dipole length was originally 140 ft but was reduced to 120 ft in an attempt to reduce resistance and reactance in the 14 MHz Amateur radio band. This is the most heavily used band during daylight hours. The IMS requirement was ability to match a dipole for all HF frequencies above its half-wave resonant frequency. Under this requirement, antenna length adjustment should not be necessary. Testing determined that this requirement would not be attainable with the system as designed. Operation on 14 MHz was desired so an attempt was made to adjust the antenna length to allow matching in this band. Figure 45 compares the dipole impedance for 120 ft and 140 ft lengths. The length adjustment lowered the 14 MHz resistance and reactance.

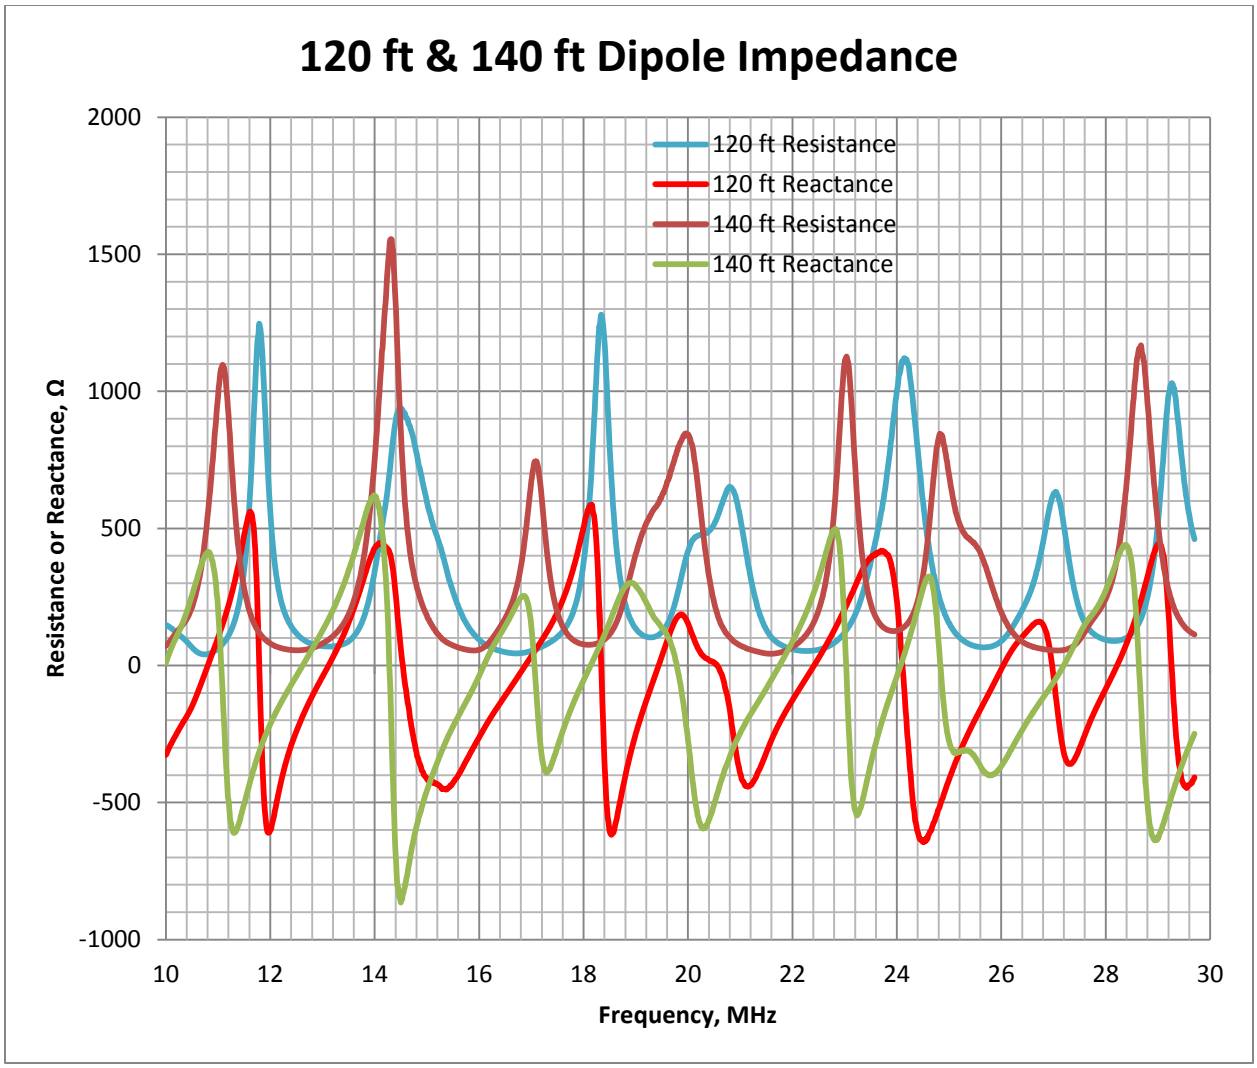

Figure 45 – 120 ft & 140 ft Dipole Impedance

Figure 46 shows the Smith chart plot of the 120 ft dipole impedance measured with an HP8753A VNA. The figure shows impedance mostly inside the r = 1 circle. Impedance outside the r = 1 circle is mostly capacitive allowing use of the Series C – Shunt L matching circuit. From 7.3 to 8 MHz, the impedance is outside r = 1 and inductive, requiring the Shunt L – Series C circuit.

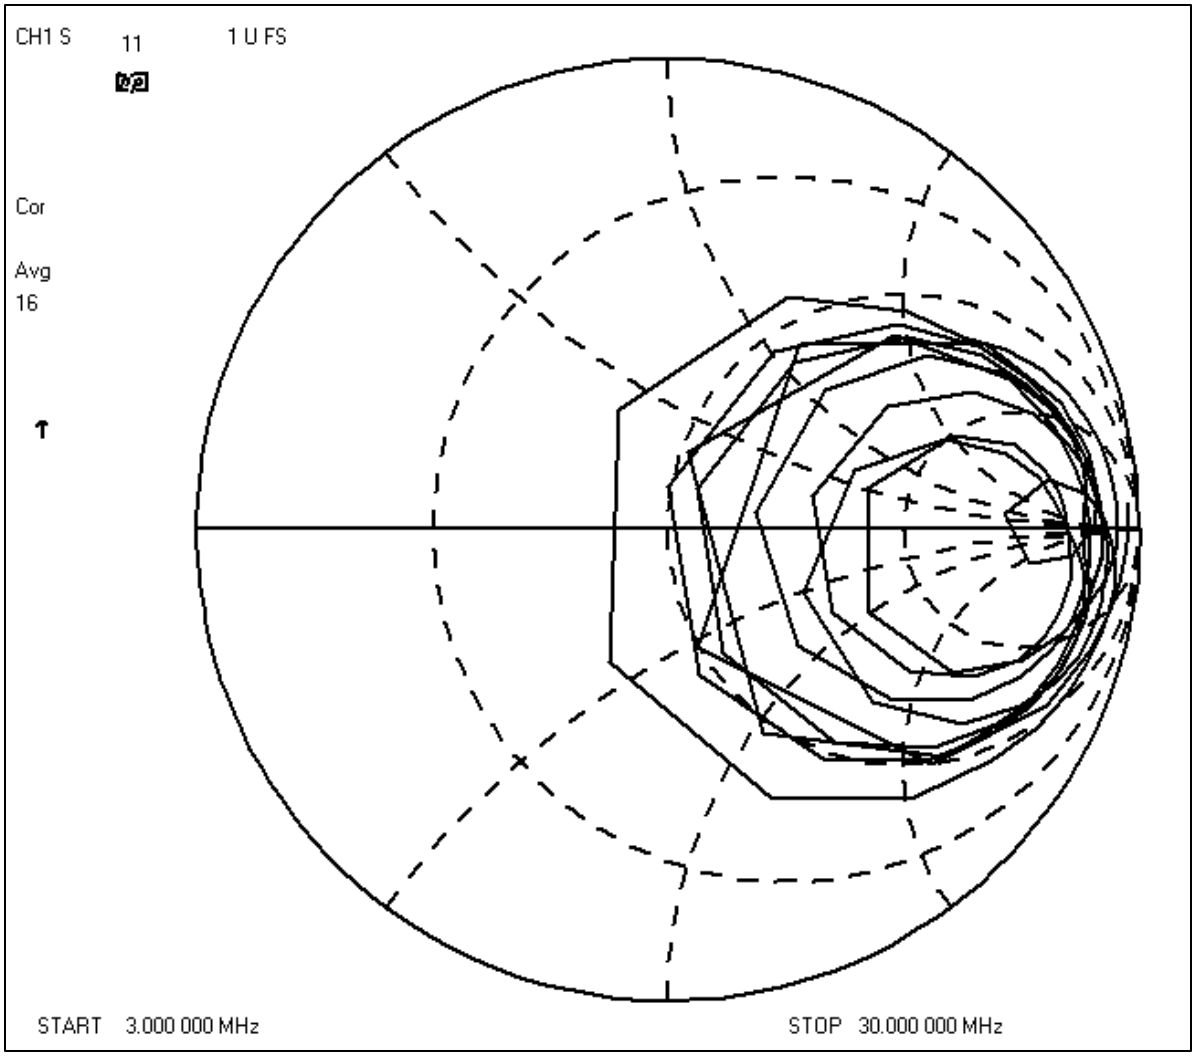

Figure 46 – 120 ft Dipole S11

Figure 47 shows the 120 ft dipole impedance from 3 – 30 MHz.

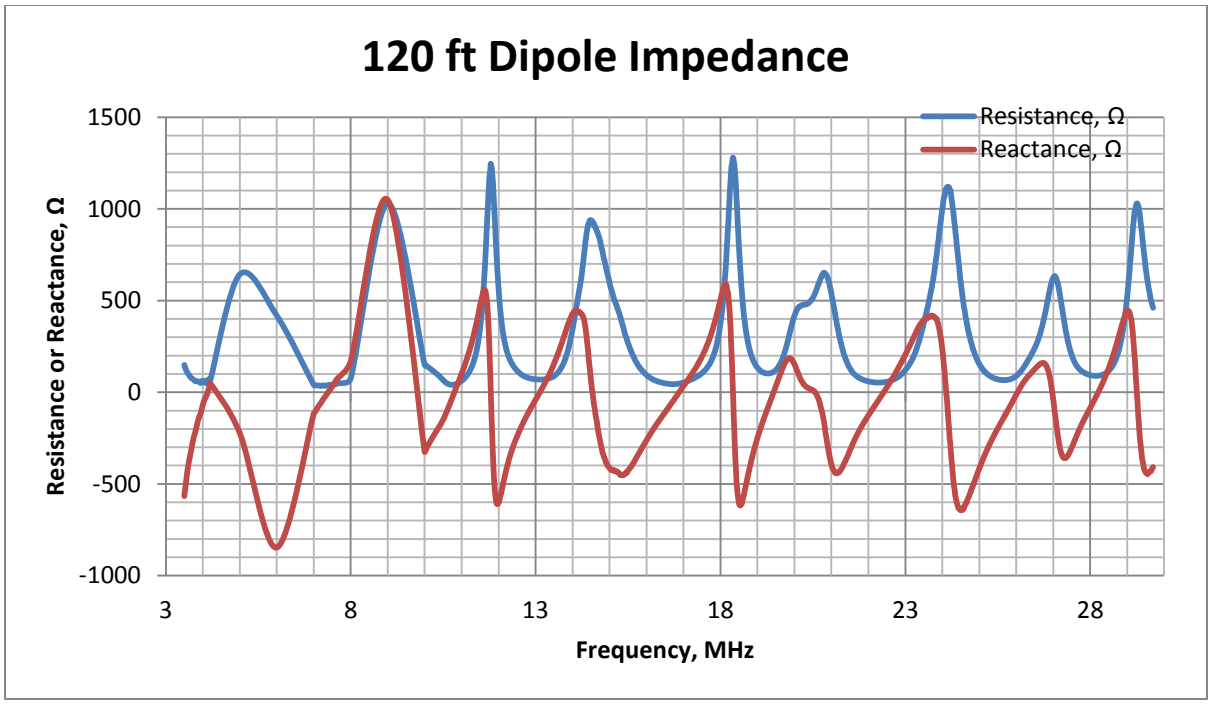

Figure 47 – 120 ft Dipole Impedance, 3 – 30 MHz

To find the IMS matching capability range, the operating frequency was set to several frequencies within all Amateur Radio bands from 3 – 30 MHz, shown in Table 6.

Automatic tuning was attempted on each frequency. If the IMS achieved a match of <1.5 SWR, the dipole impedance for that frequency was marked with an X on the Smith Chart of Figure 47. A green border encloses the matching capability impedance range.

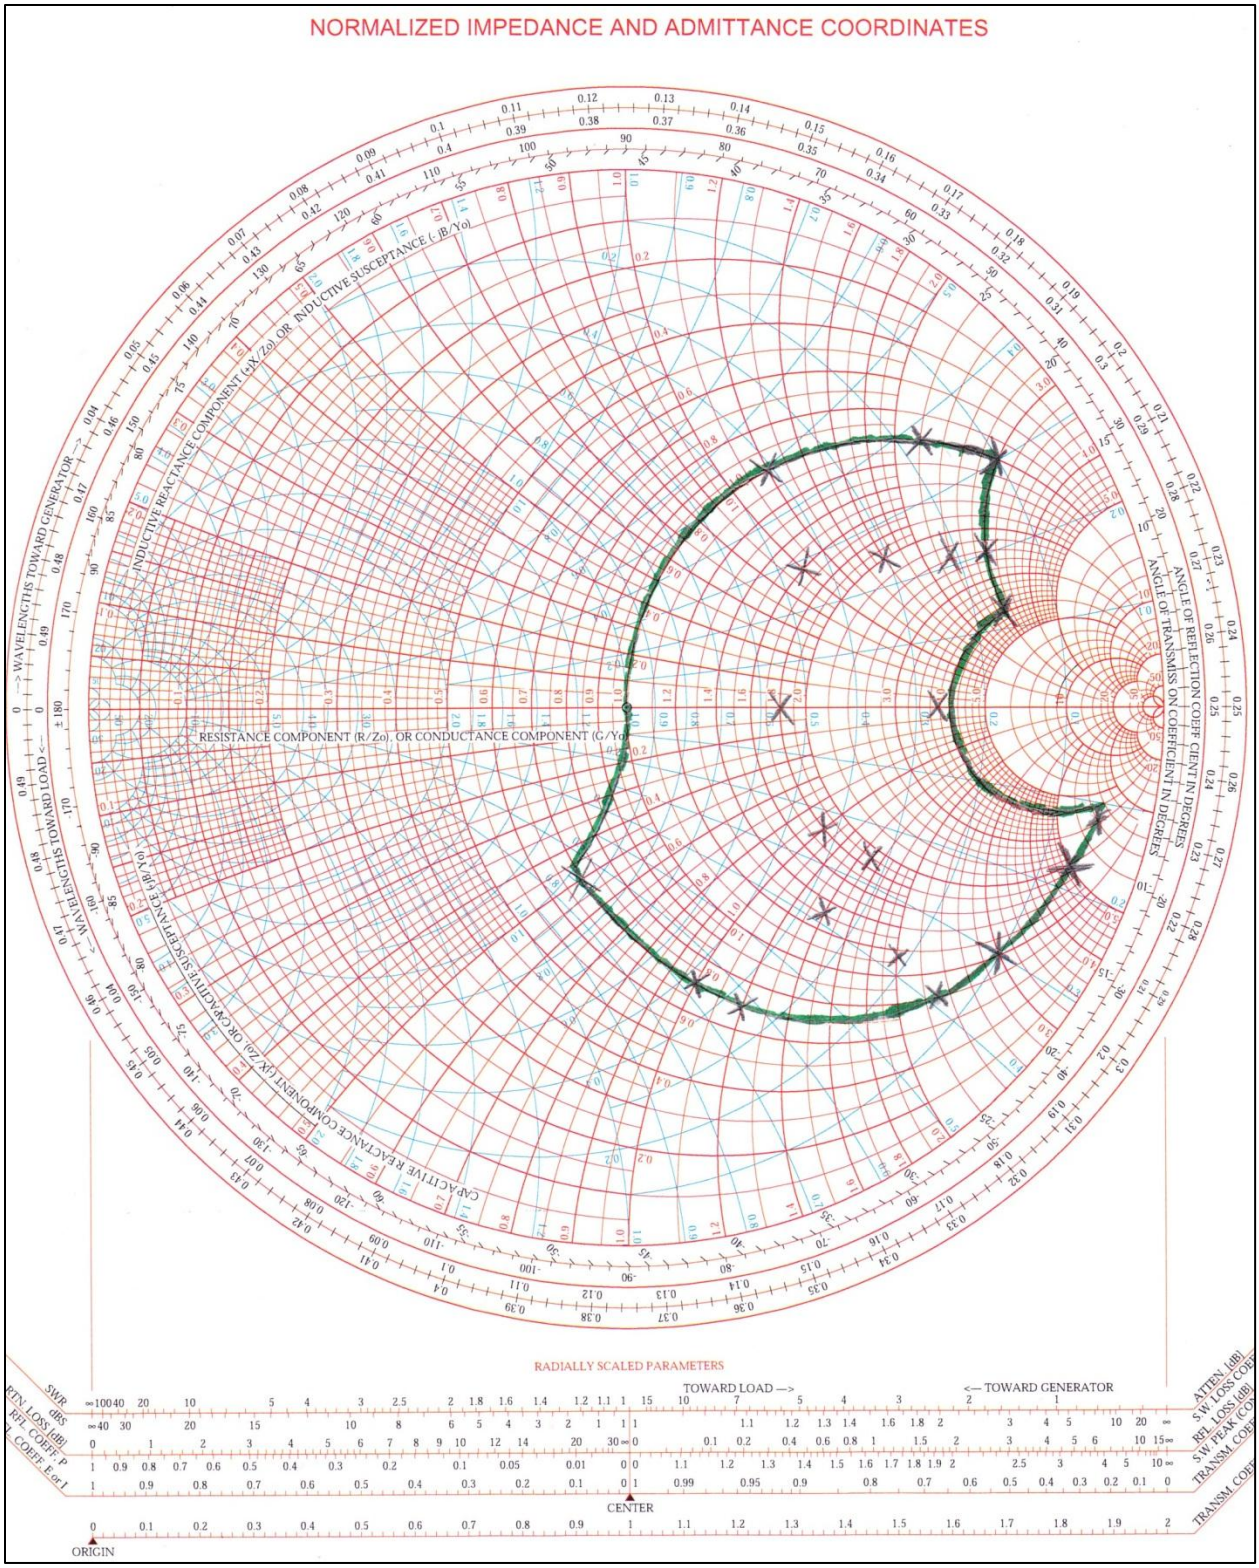

Figure 48 - Smith Chart Plot of IMS Matching Capability

Commercial automatic tuner manufacturers give tuning range specifications either in maximum SWR matching capability or impedance magnitude,| Z|, range. Equation (23) yields impedance magnitude from complex impedance, R+jX.

$$|Z| = \sqrt{R^2 + (jX)^2} \qquad (23)$$

Commercial automatic tuners have SWR matching ranges from 3:1 to 32:1. Impedance magnitude matching range is 4 – 1600 Ω [1] [2] [3] [25]. The IMS matching range is 26:1 SWR and 40-520 Ω impedance magnitude.

Since the IMS is not capable of measuring load impedance, it cannot determine the required L network configuration. The matching network switch was designed with the assumption that the IMS can match any possible load. Since that is not possible, automatic switch actuation is not enabled. If enabled, the system could fail at a matching attempt for a load impedance inside the r = 1 circle and attempt to find a match using the other network configuration, which would also fail. The tuning cycle takes approximately 100 seconds to reach the failed attempt. With automatic switching enabled, the cycle becomes 200 seconds.

Chapter 8. Conclusion

The IMS met all but one requirement specified in Table 2. It cannot match a 140 ft dipole for all frequencies between 3.5 to 30 MHz. The antenna impedance for a given frequency must fall within the range shown in Figure 48. The minimum SWR matching technique does not work for all possible load impedances since this method does not move the impedance to the r = 1 circle with subsequent capacitance adjustment to obtain the match. In Figure 48, for cases where the capacitor reactance is set ~ 0, adjusting inductance for minimum SWR places the source side impedance on x = 0 line. With x = 0, adjusting capacitance moves the impedance along constant r circle, keeping resistance constant and changing reactance. For this case, the impedance can never reach $\Gamma = 0$. The inductor must be set so the impedance approaches the r = 1 circle. The L network as constructed is capable of providing matching on all frequencies if manually tuned by trial and error. Suggested improvements include operating frequency and complex load impedance measurement. With these abilities, the tuner could attain an impedance match with only two motor adjustments. It would adjust the required element to reach the r = 1 or g = 1 circle by measuring the resistance and stopping where it equals 50 Ω, then adjust the other element to reach the match. At 40 to 100 seconds, the IMS tuning method is slow compared to commercial tuners which work in less than 15 seconds [25]. This requires the lowest possible transmitter power of 3 W to minimize amplifier heating from reflected power. The IMS does allow dipole use over a wider frequency range than otherwise possible making it a useful device for HF radio operation. Table 15 compares IMS specifications to commercial tuners.

IMS vs. Commercial Antenna Tuner Specifications		
	Commercial Tuners [1] [2] [3] [25]	IMS
Maximum SWR	3:1 to 100:1	26:1
Impedance Magnitude Range	4 – 1600 Ω	40 – 520 Ω
Tuning Time	0.5 – 15 seconds	40 – 100 seconds

Table 15 - IMS vs. Commercial Antenna Tuner Specifications

Chapter 10. Appendices

Appendix A: Senior Project Analysis

Project Title:
1.8 to 30 MHz Automatic Balanced Transmission Line Antenna Impedance Matching System

Student's Name:
William Blodgett

Student's Signature:

Advisor's Name:
Professor Dean Arakaki

• 1. Summary of Functional Requirements

The Impedance Matching System (IMS) connects in line with the transmission line between a radio transmitter and the antenna. It allows antenna use over a wider bandwidth than otherwise possible. It senses reflected power due to transmitter-antenna impedance mismatch and varies its internal impedance to achieve a match, thereby minimizing reflected power.

• 2. Primary Constraints

One challenge is minimizing project cost. There are not many part sources due to the parts' specialized nature such as high voltage variable capacitors. Due to lower economy of scale, these parts are very expensive.
A second challenge is the overall project complexity and required knowledge in subject areas beyond the Cal Poly EE curriculum. Subject areas include transmission line power measurement and stepper motor control systems. Fortunately, the curriculum provided enough basic knowledge to begin design and development.

• 3. Economic

The IMS required approximately 300 man-hours to design and build. The project also resulted in increased activity of more people than simply the person designing and building it. The parts require manufacturing, sales, and delivery. Others are involved in the production of raw

materials required to make the parts such as metals, silicon, and plastic, which are also natural capital. The IMS benefits people who use it by facilitating their radio communications efforts.

The project involved money exchange between the project owner, parts distributers, and manufacturers. If the project will be marketed to consumers, money exchange will be involved there as well.

The project required various manufactured capital items such as tools, electronic test equipment, vehicles for transportation, and computers. A vector network analyzer is the most useful tool for testing the IMS. A VNA costs $10,000 or more. Fortunately, the university makes them available for student use. A 100 W HF transceiver, typically around $1000, was used for operational testing. An accurate inline power meter ($150) was required for IMS internal power meter calibration.

All development costs accrued between September 2011 and May 2012. Manufacturing costs will accrue after this timeframe. The project owner pays these costs.

See Appendix B for a Gantt chart detailing the project schedule and Appendix C for a detailed listing of parts and development costs.

Since the IMS is an electronic device with moving parts, it will not continue to work indefinitely. Based on personal experience, the IMS is estimated to operate from 2 to 20 years before failure. This depends on many variables, the most important; how often moving parts operate. The IMS requires some periodic user maintenance, such as lubricating moving parts. Even after the IMS is no longer sold to consumers, the manufacturer should maintain support and replacement parts for the product.

• 4. If manufactured on a commercial basis:

An order of magnitude estimate for unit sales per year is 1000 based on 2 million licensed amateur radio operators worldwide. However, a small percentage would likely find the IMS affordable and would choose to buy it.

As detailed in Appendix C, the cost estimate for a prototype is $716 for parts and required approximately 300 hours to develop. At $25/hour labor, the total development cost is $8216. With the working prototype developed, the time to assemble one unit could decrease to five hours. Assuming a fixed parts cost of $716, the estimated total manufacturing cost for one unit is $841 based on $25 labor cost.

Similar antenna tuner products sell for $1500. If the IMS sells for this price, the profit is $659 per unit. The estimated gross profit per year is $659 x 1000 = $659,000. Subtracting development cost results in $650,784. This does not include all other business costs such as

taxes, insurance, employing additional workers, property, and other expenses. A true profit estimate requires a more detailed analysis far beyond the scope of this report.

The primary operating cost for the IMS is electricity. A rough estimate of the average IMS power consumption is 15 W. The California Public Utilities Commission website (http://www.cpuc.ca.gov) shows the current average electricity rate at $0.16/kWh. The electricity cost for operating the IMS is approximately 16 cents for 67 hours of operation.

• 5. Environmental

Manufacturing the IMS requires natural resources such as metals, silicon, and petroleum products such as plastic. Gathering these resources requires burning fuel, which contributes to air pollution. Mining and drilling for oil can also cause water pollution and disturb natural habitats for many species. An example is the 2010 BP Gulf of Mexico Oil Spill. Manufacturing and use of the IMS also requires electricity. Generating electricity creates air pollution and requires mining and drilling for fuel sources.

As detailed in the book *Computers and the Environment: Understanding and Managing Their Impacts*, a microchip, for example, requires 2.9 kWh of electricity and 970 grams of fossil fuel to produce. [26]

• 6. Manufacturability

Material expenses for IMS construction could be less if more of the parts, such as variable capacitors, were built in-house instead of ordered from a third party. However, building a variable capacitor from metal stock could require a significant initial investment in tools such as a stamp press to cut metal plates. If all parts including printed circuit boards are sourced from third parties, manufacturing would only involve simple soldering and machining using consumer level tools.

• 7. Sustainability

Initially, recyclable parts and materials may not be selected. This contributes to unsustainable consumption of raw material resources. Manufacturing could make use of innovative techniques to support sustainability. The challenge is that there are not many practices fully in place to make electronic devices fully recyclable. E-waste programs are ubiquitous to keep electronics out of landfills, but full recycling may require several years. According to the United Nations initiative, "Solving the E-waste Problem" (http://www.step-initiative.org/):

“Because of this complex composition of valuable and hazardous substances, specialized, often “high-tech” methods are required to process e-waste in ways that maximize resource recovery and minimize potential harm to humans or the environment. Unfortunately, the use of these specialized methods is rare…” [27]

Based on this, the IMS may not be 100% recyclable and sustainable until the electronics industry as a whole makes further progress toward full sustainability.

• 8. Ethical

The IEEE Code of Ethics [28], the Golden Rule, and Kant’s Categorical Imperative provide guidance in considering ethical implications involving the IMS project.

One possible unethical use of the IMS involves unlicensed or otherwise unlawful radio transmissions. There have been many cases of individuals deliberately engaging in malicious activities involving radio equipment. For example, people have deliberately used radio equipment to cause harmful interference or “jam” law abiding radio users. Unfortunately, there are no laws in place to stop such individuals from gaining possession of radio equipment. Fortunately, these individuals are often caught using radio direction finding equipment.

Malicious radio jamming clearly violates the Golden Rule and, more universally speaking, the Categorical Imperative. If all radio operators jammed everyone else on the radio, then radio would not be a useful communications tool. Jamming also violates Rules 1 and 9 of the IEEE Code of Ethics. It is injurious to others and can endanger “safety, health, and welfare of the public” by interfering with public safety communications. [28]

An ethical implication involving IMS design is intellectual property use. Since the IMS design incorporates unoriginal circuitry, in actuality, it will never be sold for profit since it would be unethical to profit from others’ intellectual property without their consent. The Golden Rule applies since most people would not choose to allow others to profit from their ideas. Rule 7 of the IEEE Code of Ethics says “to credit properly the contributions of others.” [28]

A positive ethical IMS aspect is its utility for emergency and international communications. As described in the Social and Political Section, it could facilitate disaster communications and communications across borders, which support IEEE Code of Ethics Rule 1 and the Golden Rule.

Last, but not least, in accordance with IEEE Code of Ethics Rules 1 and 9 and the Golden Rule, the chief consideration in the IMS design will be safety. Hazards such as fire and electric shock will be mitigated to the fullest extent practical.

• 9. Health and Safety

IMS manufacture could potentially expose workers to hazardous materials such as solder fumes, particulate matter from machining, and chemical solvents used for removing solder flux. Proper ventilation and appropriate personal protective equipment such as safety goggles and dust masks help mitigate these hazards.

Using the IMS poses some electrical hazards. It requires 120 V AC household power, which is lethal. The closed chassis protects users from this hazard provided that they do not open the chassis while the IMS is energized. The radio frequency energy from a 100 W transmitter also poses a hazard. RF energy is known to cause burns. The exposed balanced transmission line terminals on the exterior of the chassis carry RF energy at high voltage. The user and others must avoid touching them during transmitter operation.

• 10. Social and Political

The IMS could greatly benefit disaster affected communities. Major disasters often damage, overload, or otherwise limit the public telephone network availability. This hinders relief efforts. Two-way radio often provides the most reliable communications system in such situations. If the disaster is widespread, the only way to relay communications into and out of a region may be via satellite or HF radio. The IMS can facilitate disaster communications by allowing a user to set up one simple wire antenna and operate on multiple frequency bands.

In everyday Amateur Radio use, it can facilitate international communication between operators. Open dialog between people in different countries benefits international relations because people are able to understand and relate to each other better when they talk to each other rather than blindly speculate about each other.

Inequities are created because few people can afford such a device and its associated radio equipment. Also, raw materials are often produced in third world countries where workers may not profit fairly compared to the companies taking advantage of their low-cost labor.

• 11. Development

As mentioned in the Primary Constraints section, this project required advanced electrical theory beyond that taught in the Cal Poly EE curriculum. For example, the project required research into techniques and circuitry used to measure power on a transmission line. A common circuit for power measurement is a directional coupler, which provides a proportionally reduced transmission line energy sample measured using sensitive low power devices such as diodes. An additional circuit produces a DC voltage linearly proportional to forward and reflected power detected using a non-linear diode described in the ARRL Handbook [7]. Kaune [11] provides a simplified technique using an application specific integrated circuit (ASIC). Analog Devices produces a logarithmic amplifier, the AD8307, which produces a DC output voltage linearly proportional to an input radio frequency signal in dBm up to 500 MHz. These are circuits which are not included in Cal Poly EE coursework, will be very useful to the project.

Appendix B: Time Schedule Allocation

Figure 49 shows the overall IMS project schedule presented in Gantt chart form.

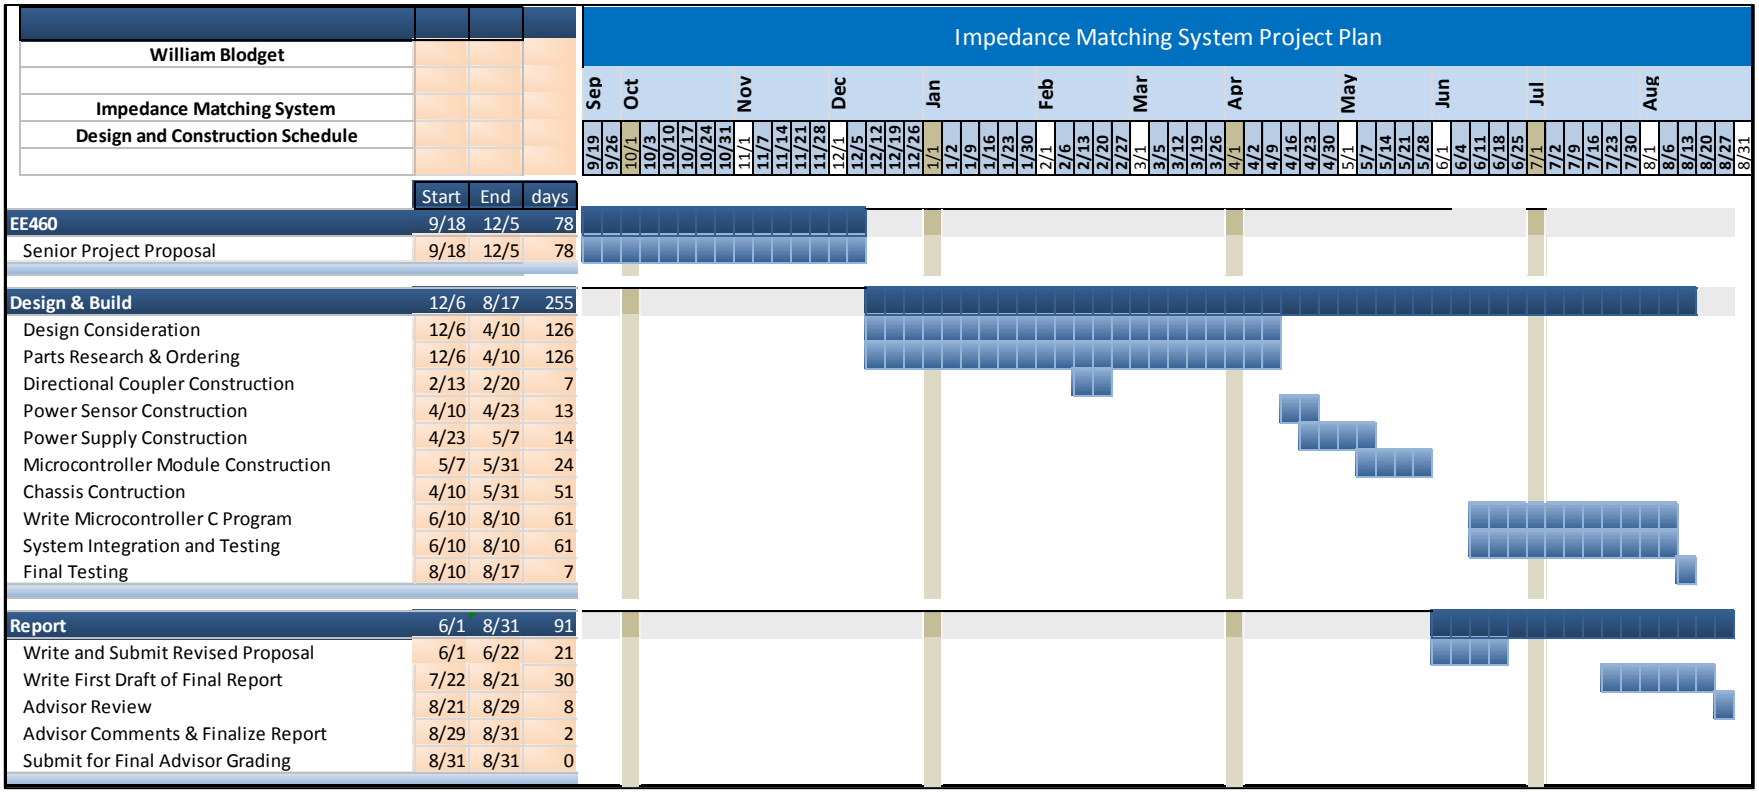

Figure 49 - IMS Project Gantt Chart

Appendix C: Parts List and Costs

Impedance Matching System Bill of Materials							
Part name	**Purpose**	**Manufacurer**	**Source**	**Part Number**	**Quantity**	**Each**	**Extended**

/*
* ---------------------------------------------------------------------
* PROGRAM DESCRIPTION
* ---------------------------------------------------------------------
* Company: Cal Poly State University
* Engineer: William Blodgett,
* Create Date: 6/7/2012 5:12:49 PM
* Description: This program runs in an ATmega32 MCU controlling an
* automatic antenna impedance matching system, also known as an
* antenna tuner. The matching network is series capacitor, shunt
* inductor L network optimized for 3.5 to 30 MHz operation. The
* inductor and capacitor are continuously variable and actuated
* by stepper motors. The shunt inductor is switchable from the load
* side to the source side providing wider impedance matching range.
* The switch is thrown by a third linear actuator stepper motor.
* The system uses a directional coupler and RF power
* sensors for forward and reflected power measurement. It displays
* this data, along with calculated SWR, inductor position, capacitor
* position on a 2 line by 16 character LCD. SWR = Standing Wave Ratio.
* It is a measure of impedance mismatch severity.
* Higher SWR = higher impedance mismatch. SWR of 1.0 is most desirable.
* The user initiates automatic tuning by first transmitting into
* the tuner and then pressing the Tune button.
* The system searches through the inductance and capacitance values
* to find the minimum SWR and improve impedance match. It attempts to
* reduce SWR to less than 1.5:1.
*
* ATUsysTest1.c

A Crystal Set for the Boy Builder

By WILL H. BATES

THIS little set is recommended for the boy builder, although the grown-ups also will enjoy it. Exclusive of the phones, the cost should not exceed $1. Surprising volume is obtained on the local stations, and the set is more selective than the average receiver of this type.

Very few parts are required. The wood base may be made of scrap material found around the home. The other items can be bought at the 10-cent store, with the exception of the crystal holder. For this, an upright type, as illustrated, should be selected, and may be obtained for about 25 cents. A good pair of 2,000-ohm phones should be used and these are available for about $2.50.

The base may be beveled on the top edges, sanded down, and then given a coat of mahogany or walnut stain. Drill it for the four binding posts, which are located as shown in the illustration of the under side of the base. A ½-in. bit is used to countersink these holes halfway through the board from below.

The spiderweb coil is wound on the form shown in the diagram; this form may be cut from fiber or cardboard, and the dimensions should be followed. The thirteen spokes are 1¼ in. long, leaving an uncut center 2½ in. in diameter. Wind the turns of No. 24 d.c.c. magnet wire alter-

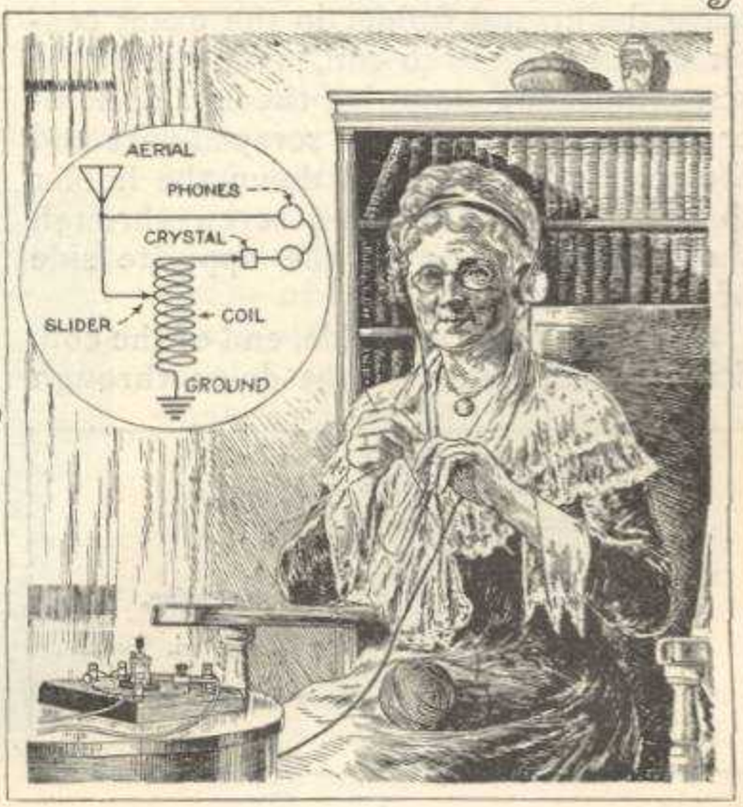
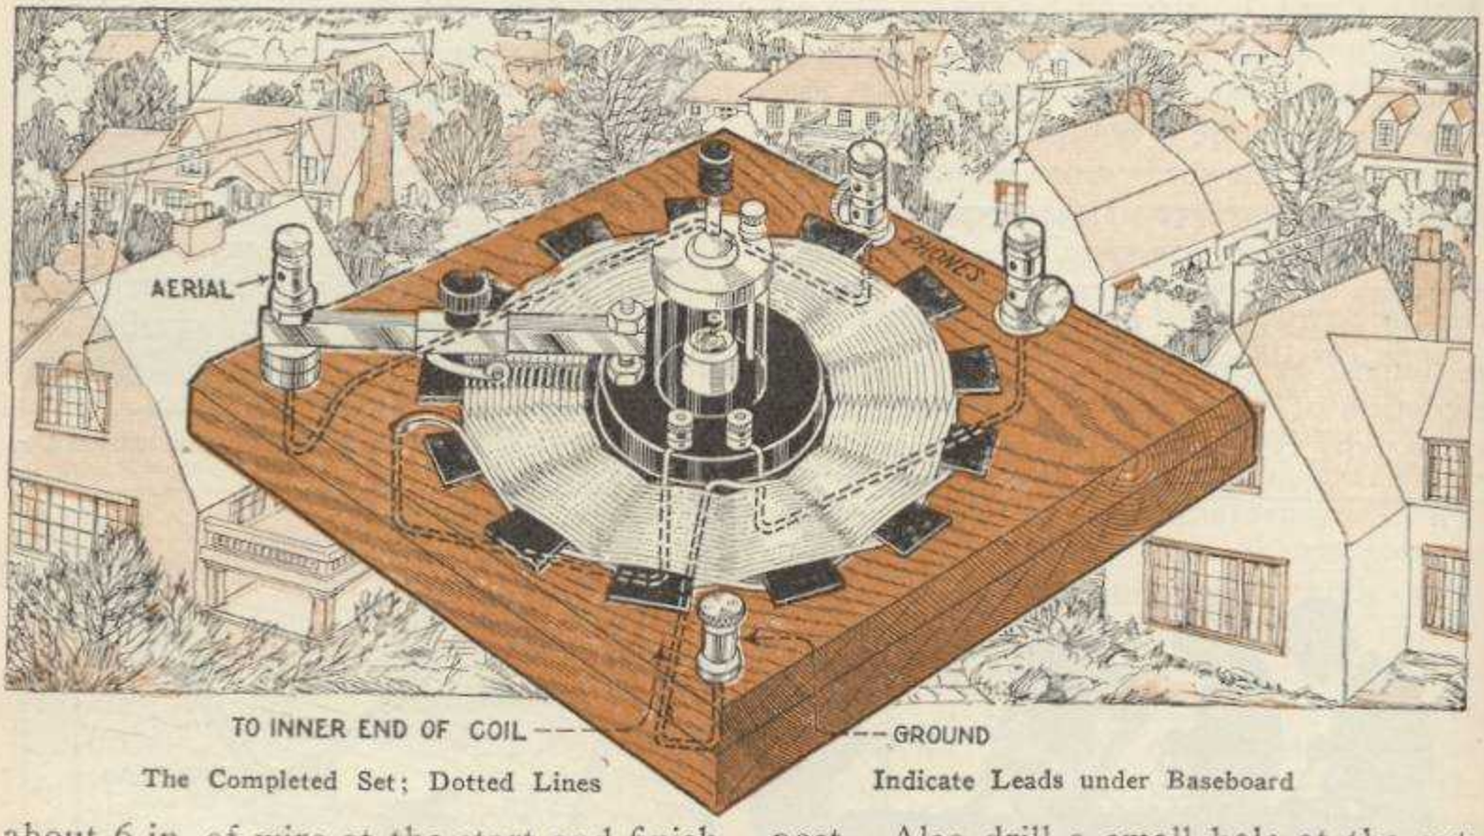
WIRING ON UNDER SIDE OF BASE



nately over and under the spokes, as indicated by the heavy line. When doing this keep count of the turns by marking one spoke and counting one each time this is passed. Fifty turns are required. Leave about 6 in. of wire at the start and finish of the coil, to make the necessary connections to the binding posts. When the coil is completed, scrape off the insulation from the wires on one of the spokes for a space about ¼ in. wide, running straight down the spoke toward the center. Put the spiderweb form on the center of the baseboard with the scraped section of the wire pointing to the aerial post. Then place the crystal holder in the exact center of the spiderweb coil, with one of the screw holes for mounting the crystal holder in direct line with the scraped wire and the aerial post. Fasten down the holder to the base with a wood screw through the mounting hole on the opposite side of the crystal holder.

At the starting, or inside, end of the coil, drill a small hole straight down through the base, and on the under side, cut a groove in a straight line from this hole to the ground binding post. Run the inside end of the wire down through this hole and along the groove to the ground post. Also drill a small hole at the outside end of the coil, and another just in front of one of the binding posts on the crystal holder. Join these two holes with a groove, and bring the outer end of the coil down through the base, along the groove and up to the post on the crystal holder. Drill another small hole just in front of the other binding post on the crystal holder, and run a wire down from this side of the crystal, through a groove alo ʒ the bottom to one of the phone posts. The other phone post is then connected with the bottom of the aerial binding post in the same manner.

With a hacksaw, cut off a section of the square slider bar, long enough to bridge the space between the base of the crystal holder and the aerial post. Measure the distance from the screw hole in the flange of the crystal-holder base to the aerial post, and drill holes in the slider bar accordingly. A 6-32 brass machine screw, 1½ in. long, is brought up through the baseboard, and through the opening in the flange. This hole is drilled down through the flange, using the hole in the crystal holder as a template. The hole on the under side of the base is countersunk for the head of this screw, which is



The Completed Set; Dotted Lines Indicate Leads under Baseboard

MATERIAL LIST

1 wood base, ¾ by 6 by 6 in.
4 binding posts.
1 spiderweb form.
1 small spool No. 24 d.c.c. magnet wire.
1 slider bar, 3 in. long, with slider.
2 6-32 brass machine screws, 1½ in. long.
1 wood screw, 1 in. long.
1 crystal and holder, upright type.
Washers and extra nuts.

not shown in the illustration as no circuit wires go to it. A nut is fitted on the end of the screw protruding through the holder flange above, and the slider bar slipped down on the nut, where it is held by another nut. At the aerial post, a brass machine screw of the same size is passed up through the baseboard, the lead from the phone post first being securely fastened to the head of the screw on the under side. Washers or a bushing should be used to level the bar. Put the slider on the bar and mount on the screw. The aerial binding post is then screwed down, and the set is ready for use.

To operate the receiver, use a one-wire aerial, about 75 or 80 ft. long, and connect a lead from the ground post to a clamp attached to a cold-water pipe. Then insert the phone-cord terminals in their posts. Tune by moving the slider along the bar until a station is heard at maximum volume and adjust the crystal to the spot where best results are obtained.

PREFACE

The Publishers make no apology for reviving interest in the crystal set. For too long the technical press has immersed itself in an orgy of complex superheterodyne receivers and television equipment, all of which is necessarily expensive. In the 1920's, crystal set construction was a fascinating and inexpensive pastime indulged in by the majority of boys of that day. Today this pleasurable hobby can be even more attractive, the introduction of the germanium crystal diode and high performance coils, has opened up new paths which will capture the interest of boys of all ages. Perhaps most important of all. not only can a receiver capable of impeccable reproduction be produced without any technical knowledge; but the cost is no greater than that of a few visits to the cinema

INTRODUCTION

Before any attempt is made to construct a receiver, it is necessary to examine the problems which surround the crystal set, so that the best can be obtained from any of the designs attempted.

Firstly, it must be understood that the crystal set as it is to-day does **not** provide any amplification. It relies entirely on what is fed into it via the aerial and earth system and gives a very faithful replica of the original transmission.

From this it will be obvious that the aerial and earth system must be as efficient as possible if the final results are to be in any way outstanding. This because these are the only means by which the signals are fed to the receiver.

Secondly it is necessary to understand the nature of the transmitted signal, then it will be easy to understand the working of the set and to appreciate the function of each of the components.

When crystal sets first became popular, very little information was generally available, at least, not in a form that school-boys could understand.

We all built sets of all shapes and sizes, with coil designs that had to be seen to be believed, but very few of us had much idea of how they worked.

I well remember the case of a cousin of mine who, in those days acquired a magnificent variable capacitor or condenser as it was then called, this instrument had a most impressively engraved dial of polished ebonite, brass vanes and nickel plated end plates. Having observed similar dials on several highly priced commercial receivers in the town, he at once ripped out the somewhat tattered coil from the family receiver and replaced it with this device. The profound silence which ensued caused considerable amazement and dismay until a better informed adult explained the mysteries of L and C to him. Readers of this manual, however, will be better informed and there is no risk of failure with any of the designs described provided the instructions are carefully followed.

The Signal

To commence, we will assume that an orchestra is playing in a broadcasting studio. Since the principle of radio transmission is electrical it is necessary to change the sound produced by the orchestra into an electrical equivalent. This is carried out by the microphone, which picks up the sound and changes it into minute electric currents.

As they appear at the output of the microphone they are too small to be of use and accordingly are passed through a high power amplifier. These amplified currents could now be transmitted, but unfortunately, as we shall learn, owing to the inherent nature of the signal in this state, transmission over any useful distance would be impractical.

When the music from the orchestra is transformed into electrical currents they are in the form of alternating currents, usually called A.C., that is they rise to a maximum in one direction, fall to a minimum, rise to a maximum in the opposite direction and then fall to minimum again. This process is repeated over and over again. One complete rise and fall in each direction is called a cycle and is drawn in Fig. 1. Every time a note is struck on a piano, vibrations are sent out which reach the ear enabling you to hear it. These vibrations are also spoken of as cycles, they rise and fall in intensity the same way as an alternating current. The number of cycles radiated by any given note over a period of one second are referred to as its frequency. Middle C on the piano sends out 261 cycles every second and is known as having a frequency of 261. The microphone also "hears" the note and in the case of middle C produces minute A.C. at 261 cycles. This can be drawn as in Fig. 2, the only difference between Fig. 1 and 2 is, that the time factor is given so that the frequency can be identified. The higher the pitch of a note the higher the frequency and the lower the pitch the lower the frequency. On a piano the frequency of the top note is 3515 cycles and that of the lower 27 cycles. Those of you who have listened to an organ in a concert hall will have noticed that when a very deep note was played, it sounded like a growl to the ear, but the vibrating fre-

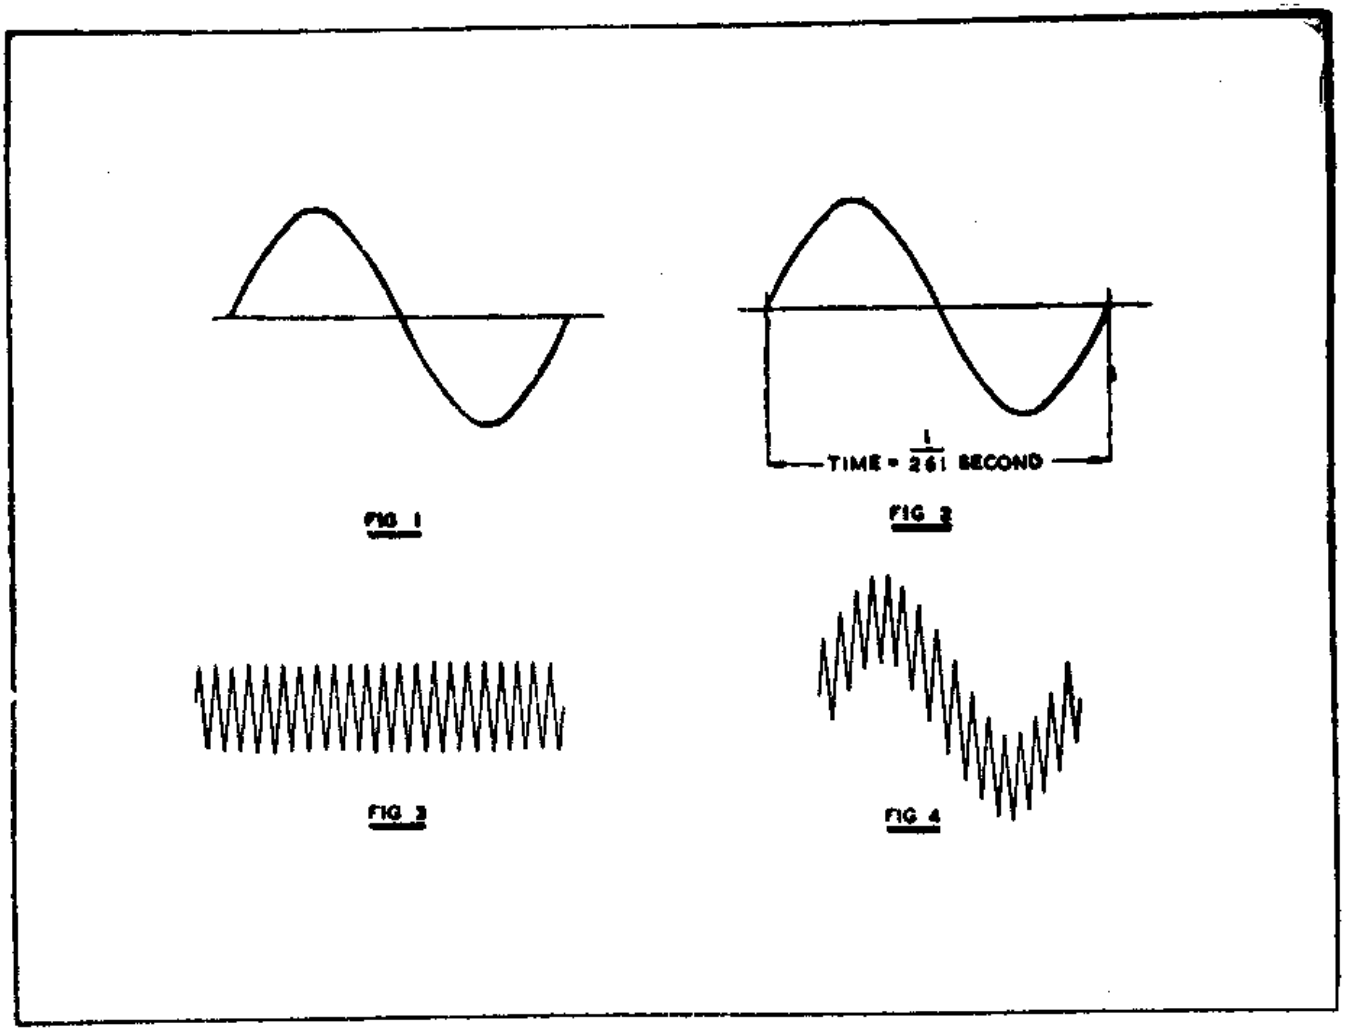

FIG 1

FIG 2

FIG 3

FIG 4

quency could be distinctly felt through the seat. Higher notes have too high a frequency to be observed in this manner.

The range of sounds which can be detected by the human ear are known as audio or low frequencies. From this you will understand that a low frequency amplifier is one which amplifies sound.

So that the transmitter will carry the programme over a useful distance it is necessary to radiate high frequencies. Now, as explained, the programme to be transmitted consists of low frequencies, and to overcome the difficulty, the transmitter generates A.C. of high frequency and combines it with the low frequencies. It will now be understood that the transmitted signal consists essentially of two different parts, a high and a low frequency content.

Fig. 3 gives a representation of the high frequency signal generated by the transmitter. In the case of the London Home Service, the frequency is 908000 cycles.

When referring to a high frequency signal on the medium or long wave-band it is usual to express the frequency in thousands of cycles, thus 908000 cycles becomes 908 kilo-cycles, which in turn may be abbreviated to 908 k/cs. It might at first be thought that by adding the low frequency or L.F. signal to the high frequency or H.F. carrier a form such as in Fig. 4 would result, such a combination is useless, and, so that the original L.F. content can be satisfactorily extracted by the receiver, the L.F. signal must vary the amplitude or output power of the H.F. signal as in Fig. 5.

It is in this form that the signal arrives at the receiving aerial. The aerial in itself is incapable of discriminating between one signal and another, and countless signals will be collected by the aerial at any one time. Many of these are too weak to be of use but the stronger ones must be sorted out since there is no point in receiving several programmes at once.

Fig. 6 shows the basic circuit of the input to a crystal. The coil L possesses a quality known as inductance, and the capacitor C, that of capacitance. If the coil had no capacitance whatever across it, all signals arriving at the aerial would be effectively short circuited to earth. As a matter of interest, it is impossible to obtain this state of affairs since even without any additional capa-

citor any coil **must** contain a certain amount of self capacitance.

By combining a coil and capacitor as in Fig. 6 a peculiar effect is observed, at one particular frequency, the signals are not short circuited to earth, but are developed across the coil. In other words the combined effect of L and C no longer provides a short circuit, **but only at one particular frequency.** If the value of C is altered the effect will be observed at a different frequency; likewise by altering L the frequency at which the effect will take place can be changed. There is a name for this phenomena, the frequency at which it occurs with any given L and C combination is known as the **resonant frequency.**

The values of the coils and capacitors shown in this manual have been carefully chosen so that resonance will be obtained at all frequencies where stations are broadcasting. Broadcasting stations work in bands of frequencies, those of major interest to crystal set constructors are the medium wave-band 1200 k/cs—600 k/cs and the long wave-band 300 kc/s—150 k/cs.

Usually a variable capacitor is used with a fixed inductance to cover one band and an additional coil switched in to increase the inductance to cover the other. In this way the L and C combination can be adjusted to provide resonance at the desired frequency of any given station. In other words you can **select** the station you want by varying C, that is turning the dial of the variable capacitor. This procedure is referred to as tuning. Having selected or tuned the required station it still remains necessary to change the form of the signal back to that of the original transmission. This process is called detection or de-modulation.

Examination of Fig. 5 will show that the signal has been duplicated, in other words, as it rises in one direction it also rises equally in the other. In this form the signal is useless since each half of the signal cancels the other, and if this signal is applied to a pair of headphones silence will result. Obviously some provision must be made to get rid of the unwanted half of the signal, and it is here that the crystal detector must be considered. This device will pass current in one direction only, ignoring any signal in the opposite direction, so that if the signal of Fig. 5 is passed through such a crystal, that of Fig. 7 will result. There is still the H.F. content to be reckoned

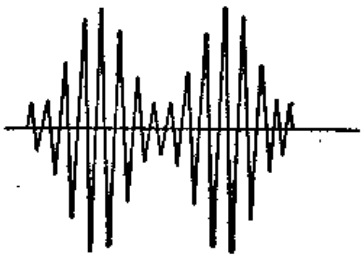

FIG 5

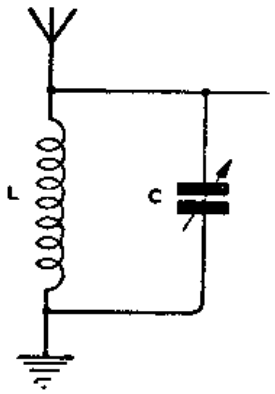

FIG 6

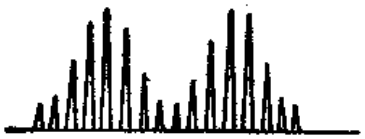

FIG 7

FIG 8

with, fortunately this is easily dealt with, a capacitor connected across the headphone terminals effectively disposes of this, leaving only the audio or L.F. content, as shown in Fig. 8. This audio content, which is a faithful replica of the original transmission is fed to the headphones. These in turn reverse the process of the microphone and transform the electrical currents into sound waves acceptable to the human ear.

Briefly then, your requirements are as follows:—

(1) A good aerial and earth installation, to make the most of the available signals.
(2) A receiver containing:—
  (a) Some form of coil and capacitor (L & C) combination to select or tune in the wanted station.
  (b) A crystal to get rid of the unwanted half of the signal (detection).
  (c) A fixed capacitor across the headphones to get rid of any remaining carrier.
(3) A pair of sensitive high resistance headphones.

Aerials

By this time the intending constructor will be able to appreciate the necessity of a good aerial. It is a point which cannot be over-emphasised. Assuming that you are in the fortunate position of being able to erect an outdoor aerial there are two main considerations, height and length.

One of the best that can be used is the inverted L shown diagramatically in Fig. 9.

It should be erected as high as is practical, every foot counts. The horizontal wire, that is the aerial proper, should have a minimum length of 60′ to which of course the length of the down lead is added. Where it is impossible to erect an aerial with an ideal horizontal length, a compromise must be effected.

Fig. 10 shows a three wire spreader aerial which gives quite a good effective length.

Suitable wire for a receiving aerial will not set any problems, stranded copper about 7/22 gauge is the best. 7/22 means that it consists of 7 strands of 22-gauge wire. This wire may be obtained covered, and for the present purpose is better than the plain or enamelled kind.

Note that insulators are used between the actual aerial wire and its anchoring supports, it is important that these are used, otherwise leakage will occur which will of course spoil its efficiency. Fig. 11 and 12 show how the wire may best be attached to two of the most common types of insulator available. Fig. 11 is of porcelain and is usually referred to as an egg insulator, whereas Fig. 12 shows a more modern (and more expensive) type in glass. If you are using the glass pattern, one is usually sufficient at each end of the aerial, but with the egg type two should be used. No doubt many readers will not be in a position to erect an out-door aerial, and must necessarily be content with an indoor installation.

The next best thing to a good out-door aerial is a replica constructed in a loft. If this form of construction is used, care must be taken when feeding the down lead to avoid close contact with the wall of the house. At the point where the lead feeds under the eaves, a length of rubber tubing can be used to cover the wire. The lead is fed through one of the small spaces left for ventilation purposes. A general idea is given by Fig. 13.

A less elaborate but quite effective aerial can be obtained by using a bed-spring. A length of 7/22 copper insulated wire is connected between the receiver and the spring. The spring should first be cleaned with emery cloth. Remove about 2″ of insulation from the wire and bind it tightly round the prepared spring. The joint may be covered with insulating tape which is obtainable from all electrical stores for a few pence.

Such aerials are quite popular since so many crystal sets are built for bedroom use.

When an aerial is required in the living room, the picture rail can be conveniently used. Insulated screw-eyes are fixed at intervals of about 3 feet along the rail, the wire is firmly anchored to one of them, and stretched right round the room until you arrive back at the starting point. By use of one of the insulated screw-eyes, the wire is secured and the down lead fed to the receiver. The idea is illustrated in Fig. 14.

Soldering

Before leaving the subject of aerials, a few words on soldering will not come amiss. Down leads on outdoor aerials should be soldered, and the same applies to loft types. Apart from aerial leads; earth leads and all the connections in the receiver will require soldering.

For the type of soldering necessary in radio construction an electric iron is the best solution. One of the small types marketed by Adcola or Henleys will be found admirable for the job. These are excellent for actual set construction but are hardly large enough for soldering the down lead to an outdoor type of aerial. Here the heat is dissipated much more quickly and a larger iron is required in order to get the solder to flow.

Ordinary irons which may be heated by a gas flame can be obtained very cheaply from most ironmongers' stores. Assuming the use of such an iron, first heat the iron until the copper bit is giving off a green coloured flame, the iron is now at the correct operating temperature. The bit is now discoloured or oxidised and its tip

FIG. 14

should be quickly cleaned with an old file which should be kept specially for the purpose. A better idea is to obtain a small block of sal-ammoniac and rub the tip of the hot iron on it. This will clean the tip of the bit perfectly. Next take a length of cored solder such as Ersin Multicore, and melt a little on to the prepared tip faces, now smooth it evenly over the surface with a piece of old rag (be very careful not to burn your fingers) the iron is now "tinned" and ready for use. When heating the iron, be very careful not to let the bit overheat or get red hot, otherwise the tinned surface will be destroyed and the whole process will have to be gone through again.

An electric iron will not overheat, and the tinning will last much longer than with ordinary types, and since the heat does not deteriorate there is less likelihood of making faulty joints.

Having obtained a tinned iron, the process of soldering joints is remarkably simple and anyone with a little patience can acquire the art in a very short time.

To solder two copper wires together: clean the wire with emery cloth, apply a prepared iron and some cored solder to it, the solder will flow evenly over the wire thus tinning it. Repeat the process with the remaining wire and then twist the two together. Now apply the iron to the joint from the underside and the cored solder to the joint on top. Solder will flow evenly over the joint. Remove both iron and solder and allow to set. The solder will harden or set in a few seconds but during this period the joint must not be touched or moved, as otherwise the joint will be "dry" and quite useless mechanically or electrically. On radio components, tags for soldering are already tinned though if they are old, or discoloured it is best to re-tin them. Normally, however, it is only necessary to twist the connecting wire to it and apply the iron and solder as explained.

Remember: **never** apply the solder to the iron and then the iron to the joint, always apply the iron **and** the solder to the joint. It is however a good thing to apply a little solder to the iron tip even when it is perfectly tinned just before making a new joint.

One final "DON'T," you will have noticed that the solder referred to is "cored," that is, it contains resin and other substances through its centre, plain solder as used by electricians and plumbers will not do, as it is the resin or flux

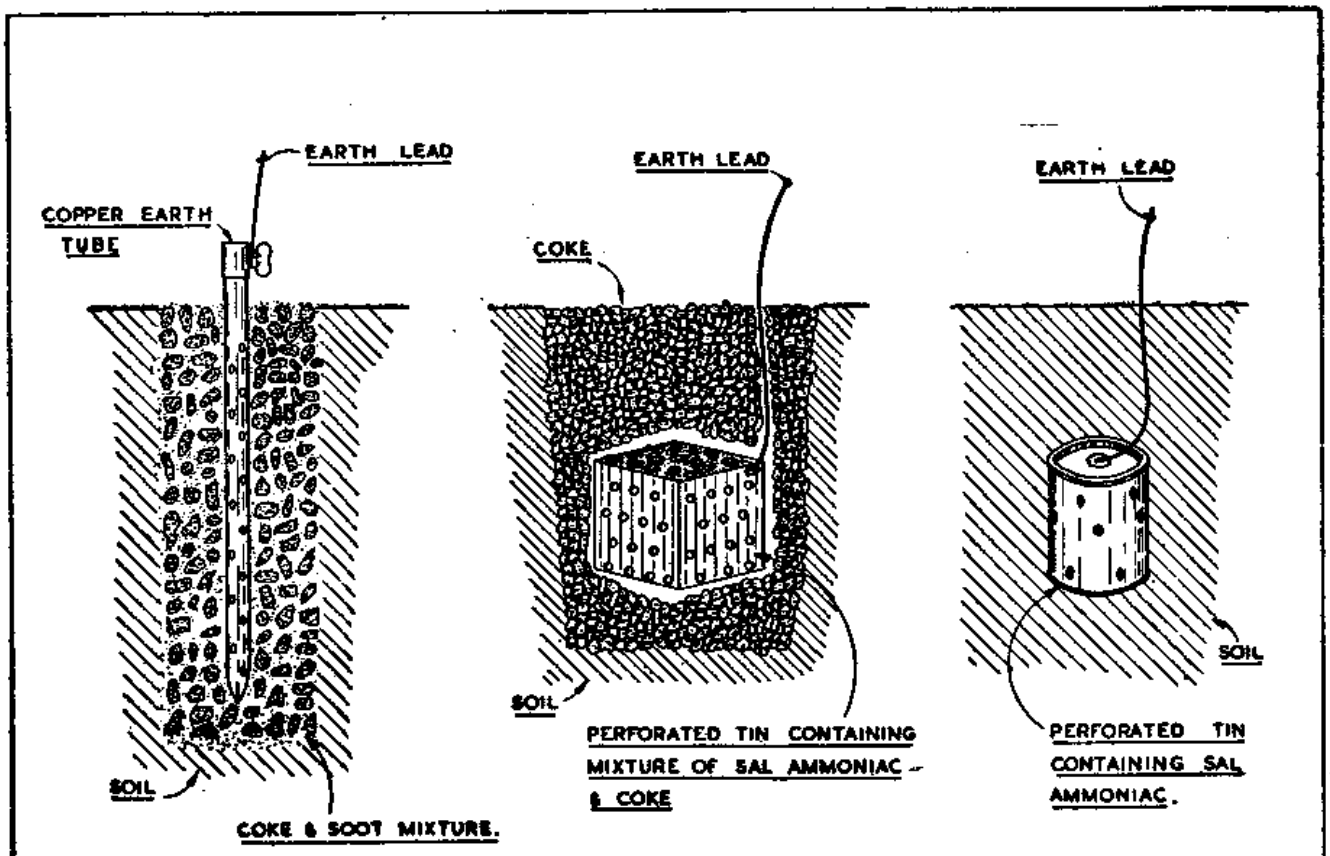

FIG. 15.

as it is called which makes the solder flow evenly and permits a good electrical joint.

Equally important do not attempt to use a separate flux or soldering fluid with plain solder or to "help" the cored solder, since these are almost certain to cause eventual corrosion and will destroy any components that have been contaminated.

Earths

The provision of a good earth is just as important as the rest of the installation.

Much disappointment would be avoided if this fact were not lost sight of, to avoid any slip up in this direction I am proposing to outline several well tried and efficient earth systems.

If it can be obtained, an earth rod, specially designed for the purpose provides the basis of a good earth connection. These were very popular some years ago when the majority of receivers were either crystal or battery operated, but in these days of modern mains driven sets they are not often used and consequently not always readily available.

Fig. 15 shows how it is used. First excavate a hole to a depth of three feet and fill with a mixture of soot and coke. Drive in the earth rod, which is a hollow copper tube, perforated. The lead to the receiver is connected at the top, and should be of covered 7/22 gauge, as used for the aerial system. Though not obvious it is important that this lead-in should be in covered wire, otherwise a number of indifferent earth contacts are likely to be made at various points along its length until it reaches the set. This is very undesirable and will spoil the efficiency of the system. It is essential to keep the soil surrounding the rod moist, which is one reason why the tube is hollow, and care must be taken to pour water into the tube at intervals.

A very efficient earth is the percolative type also popular at one time. Due to the chemicals used, it will extract moisture from its surroundings, thus maintaining a permanently moist earth.

It should be installed as in Fig. 15b.

The container is of copper or zinc, anything else will quickly rust away, again a good quantity of coke is used. Fill the container with a mixture of sal-ammoniac and coke, and then bury in coke as illustrated. This earth will not require further attention. It is possible to use powdered calcium chloride instead of sal-ammoniac but unless a chemist can be persuaded to make some up it is better to stick to sal-ammoniac.

If a zinc container is not available and you do not use or cannot easily get coke, Fig. 15c should be used. This makes a better earth than many so-called "earths" that I have come across. Obtain as large a tin as possible, make a number of holes as shown. Solder the lead in the bottom and fill it with sal-ammoniac. Replace the lid and bury in the ground. The tin will eventually rust away, but the replacement cost is negligible.

If it is quite impossible to make direct contact with the ground, a water pipe must be pressed into service. This should be a main pipe feeding straight to ground and not a hot water pipe or one fed from a tank. Scrape the pipe clean and twist the lead in tightly around it, a copper clip is even better. Do not attempt to solder on to the water pipe; since cold water is flowing through the pipe, it is extremely unlikely that your soldering iron will heat up the water supply sufficiently to allow a sound electrical joint, though you may spring a leak.

No attempt should be made to utilise gas pipes; the possibility of causing a fire is certainly very remote but, they make incredibly bad earth connections due to a number of joints made before true ground is reached. These joints are at best only semi-conductors, at least from an electrical standpoint.

Headphones

Since the late war there have been a large number of head-phone sets available on the surplus market. These may be roughly divided into two types, high-impedance and low-impedance. For the crystal sets detailed in this book high-impedance 'phones are required and the low-impedance pattern will not be suitable unless a matching transformer is used. As this is likely to cost more than the rest of the installation including the set, it will be as well to avoid them.

High-impedance types have an impedance of 2000Ω to 4000Ω whereas the low-impedance types are usually 600Ω.

The remaining consideration is weight; often cheap headphones are very heavy and uncomfortable to wear, every endeavour should be made to obtain 'phones as light in weight as possible.

Crystals

All the sets shown in this book have been designed to work with modern germanium crystals rather than the older galena crystal.

These germanium crystals require no adjustment, which, in itself, removes the main objection to this class of receiver. Suitable crystals are available from the following manufacturers and on the surplus market: Mullard, G.E.C., Brimar, Westinghouse and B.T.H. They are of robust construction, some in glass, others in ceramic or plastic, but must not be subjected to heavy knocks, otherwise the contact point may become dislodged.

From the information given, you should now be able to install an excellent aerial and earth system, and have some idea of how the crystal set works, so it is time to pass on to the actual receiver construction.

CONSTRUCTION 1

If you examine the following circuits you will find that each one is different. In most cases the difference lies in the coil design and/or the method by which the crystal and aerial is tapped into it. Each of these circuits has its own particular advantage to suit different conditions and the ideal circuit in some localities is not necessarily the best in others. It is not just a matter of a given circuit giving louder results than another, if it were there would be no point in showing more than one.

The main problem is to obtain adequate selectivity without reducing the volume level.

A receiver is said to be selective when it tunes sharply, a set with poor selectivity allows the stations to spread over the dial and when used near a transmitter will receive the local stations mixed together, which of course is useless.

Consider Fig. 16a, this is a very simple receiver, with no special attempt to provide any great amount of selectivity. In areas where signal

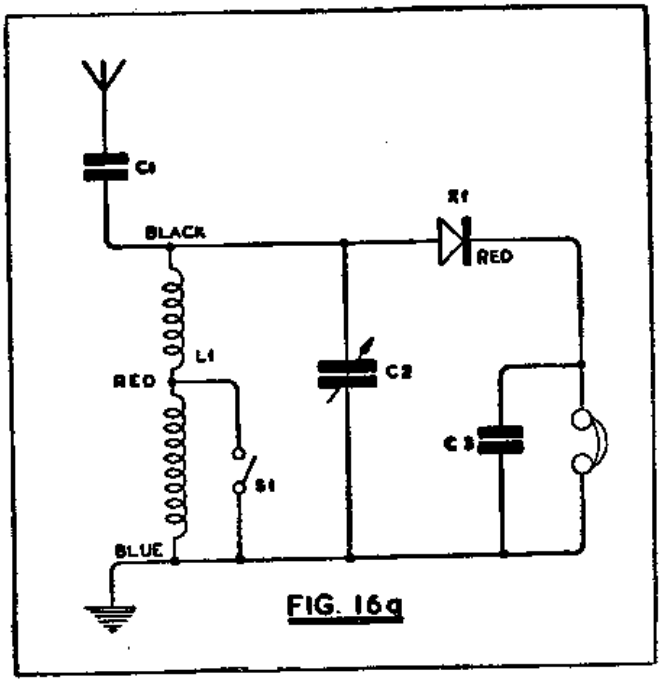

FIG. 16a

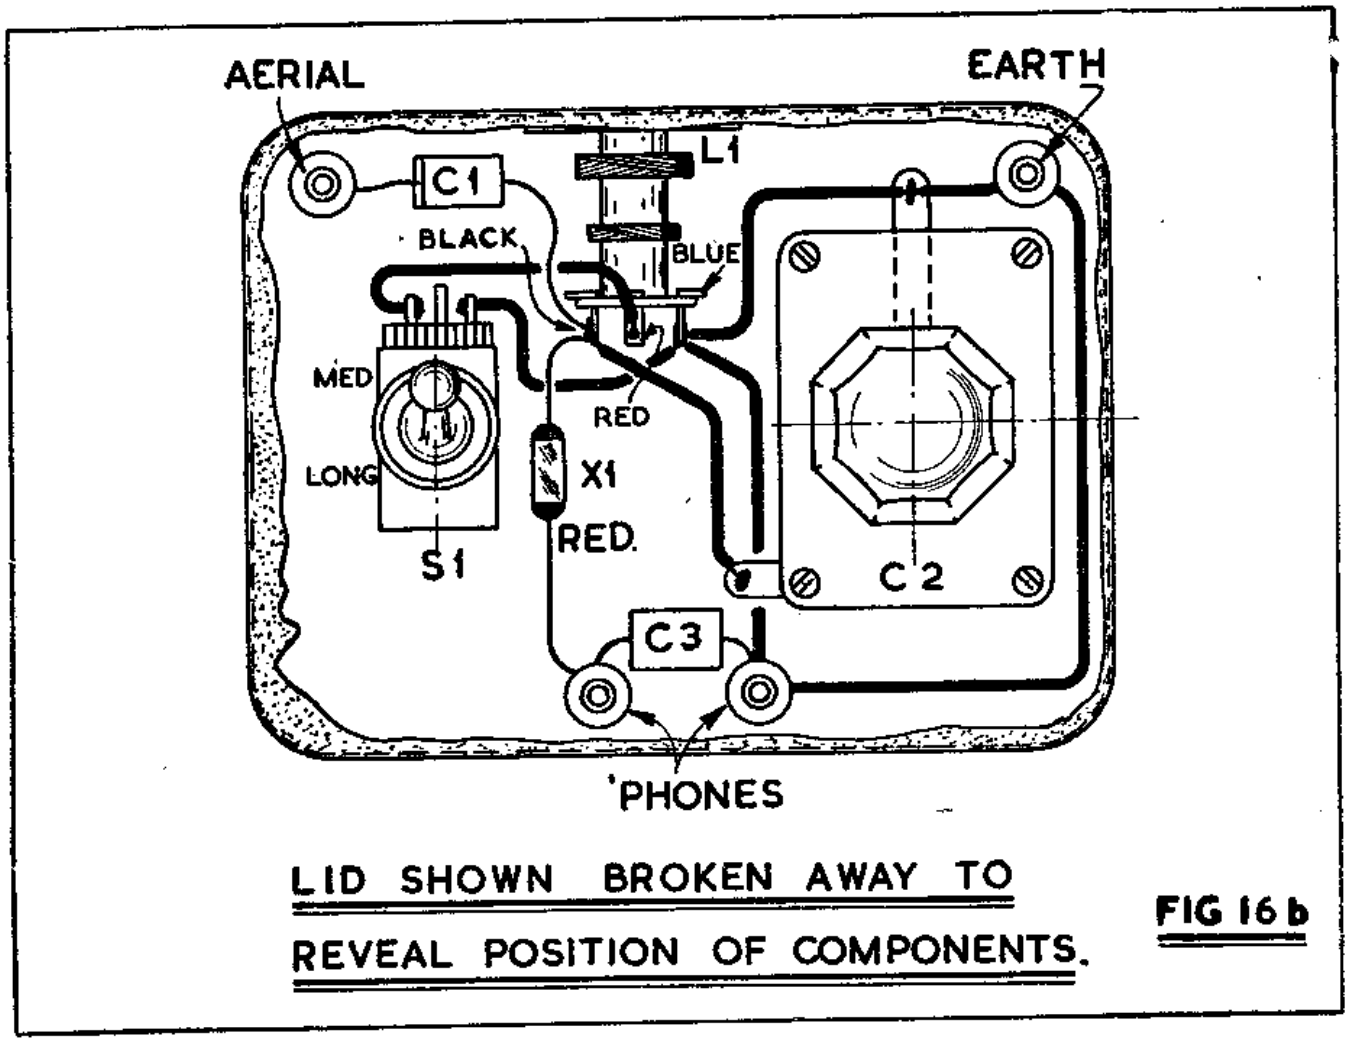

LID SHOWN BROKEN AWAY TO REVEAL POSITION OF COMPONENTS.

FIG 16b

strength is not high, or a short aerial is used, it will probably be ideal.

It would have been quite easy to increase the selectivity by providing a tap on the coil for the aerial as in Fig. 17a, but unfortunately, as the selectivity is increased overall volume is likely to decrease, so that unless you live close enough to the transmitter to have a large signal available and therefore need the selectivity, the circuit of Fig. 16a will be quite satisfactory.

Capacitor C1 is to prevent the aerial damping the circuit too heavily because this would flatten the tuning unnecessarily, however with small aerials it may be better to take the aerial direct to the black tag on L1. The signals are selected or tuned by L1 and C2, X1 is the crystal and C3 the capacitor across the 'phones to prevent unwanted carrier or R.F. reaching the 'phones.

A practical diagram (Fig. 16b) is provided showing the layout and all the wiring. You will require nuts and bolts to fix the coil, about ½", 4BA size will do, the other parts have locking nuts provided. An old 2-oz. tobacco tin makes a very good container and keeps the size down. Note that the metal box is connected to earth. With the exception of AC/DC receivers the metal work on any receiver or amplifier is connected to earth.

When S1 is open as in the diagram, the set will tune in long-wave stations, but when closed the medium wave-band will be received.

Components List, Fig. 16a

C1	100pF mica capacitor.
C2	500pF tuning capacitor, solid dielectric.
C3	1000pF mica capacitor.
X1	Germanium crystal.
L1	Crystal Set Coil. R.E.P.
S1	Single Pole toggle switch.
4	Insulated wander-plug sockets and plugs.
1	2-oz. tobacco tin (or similar container).

Make sure that the wander-plug sockets are of the **insulated** type, otherwise the metal case will join all the sockets together electrically.

Try to follow the theoretical diagram when wiring, a little practice will soon enable you to wire up a set without a practical diagram, which is a great advantage because often only the theoretical diagram is given when circuits are detailed in the technical press.

Fig 28 on page 34 gives a list of symbols used on the theoretical diagrams, so that you can readily identify the components.

2

Fig. 17a circuit is similar in many respects to that of Fig. 16a. The difference is purely one of selectivity, tuning will certainly be sharper, and even with comparatively inefficient aerials the design will put up a very good performance. There is no reason why the construction should not follow the same lines as the previous receiver but, by enlarging the set a little and using an air spaced tuning capacitor, the efficiency is improved. Observe that the colour coding on the coil, an R.E.P. Dual Range (Blue Box) is different from that of the Crystal set coil used on the previous design, and make sure it is correctly wired in.

C1 is a mica compression capacitor, often referred to as a "trimmer" and because it is adjustable, permits the set to be matched to aerials of varying lengths. Construction is carried out on a square panel of bakelite, perspex or wood, as shown in Fig. 17b. Perspex being clear like glass presents a most attractive finish, provided the set is neatly wired. It must be drilled slowly, however, otherwise the generated heat of the drill will make the hole wander, and spoil the panel.

After the set has been wired and tested a small wooden container can be made to house the completed set.

When carrying out reception tests, a little experiment is well worth while, to get the best out of the set. Try removing the germanium crystal

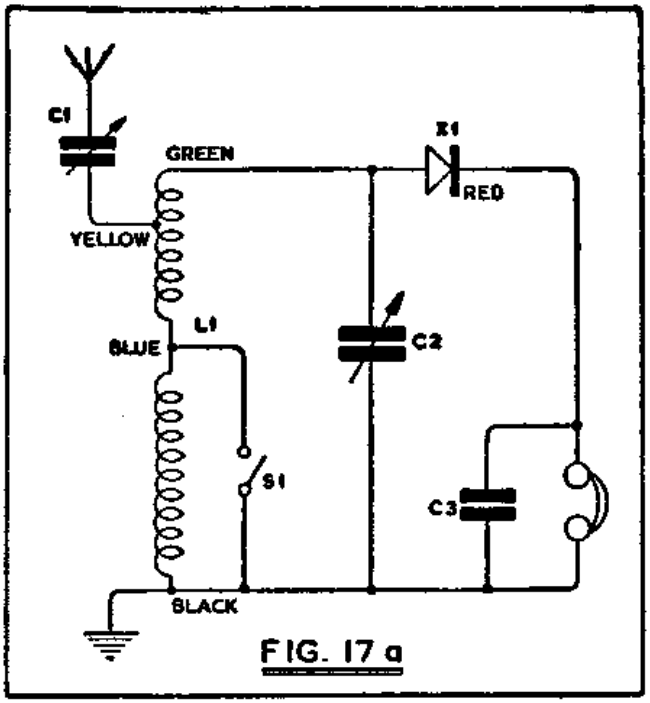

FIG. 17a

from the green tag on L1 and connecting it to yellow, at the same time removing the lead from C1 to yellow and connecting it to green. Once the best arrangement has been found the wiring

can be left permanently in that position. Note that two tags on the coil are unused, this is intentional because on this circuit the extra winding connected to these tags is not required. With the switch S1 closed, the coil will cover the medium wave-band, and when open, long wave stations can be received. It is customary to abbreviate the expression medium wave-band to M.W. and long wave-band to L.W.

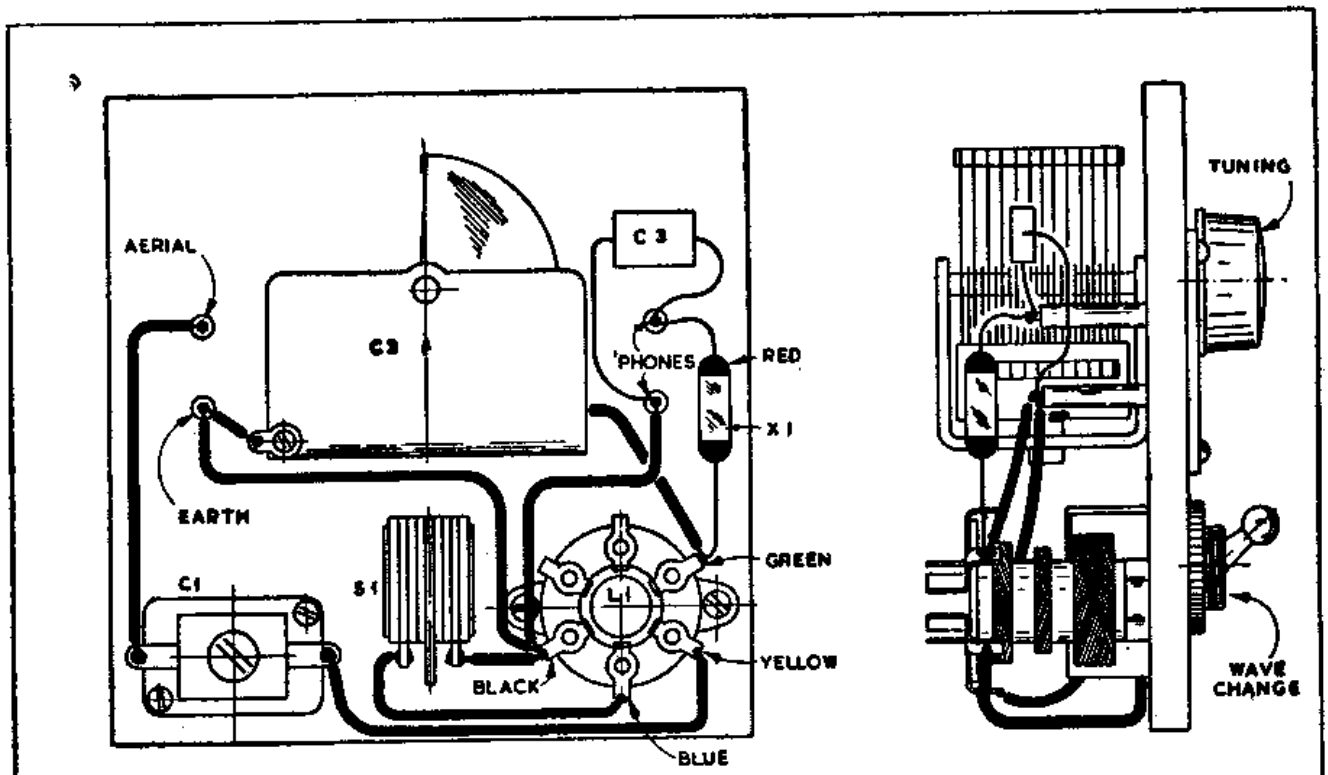

FIG. 17 b

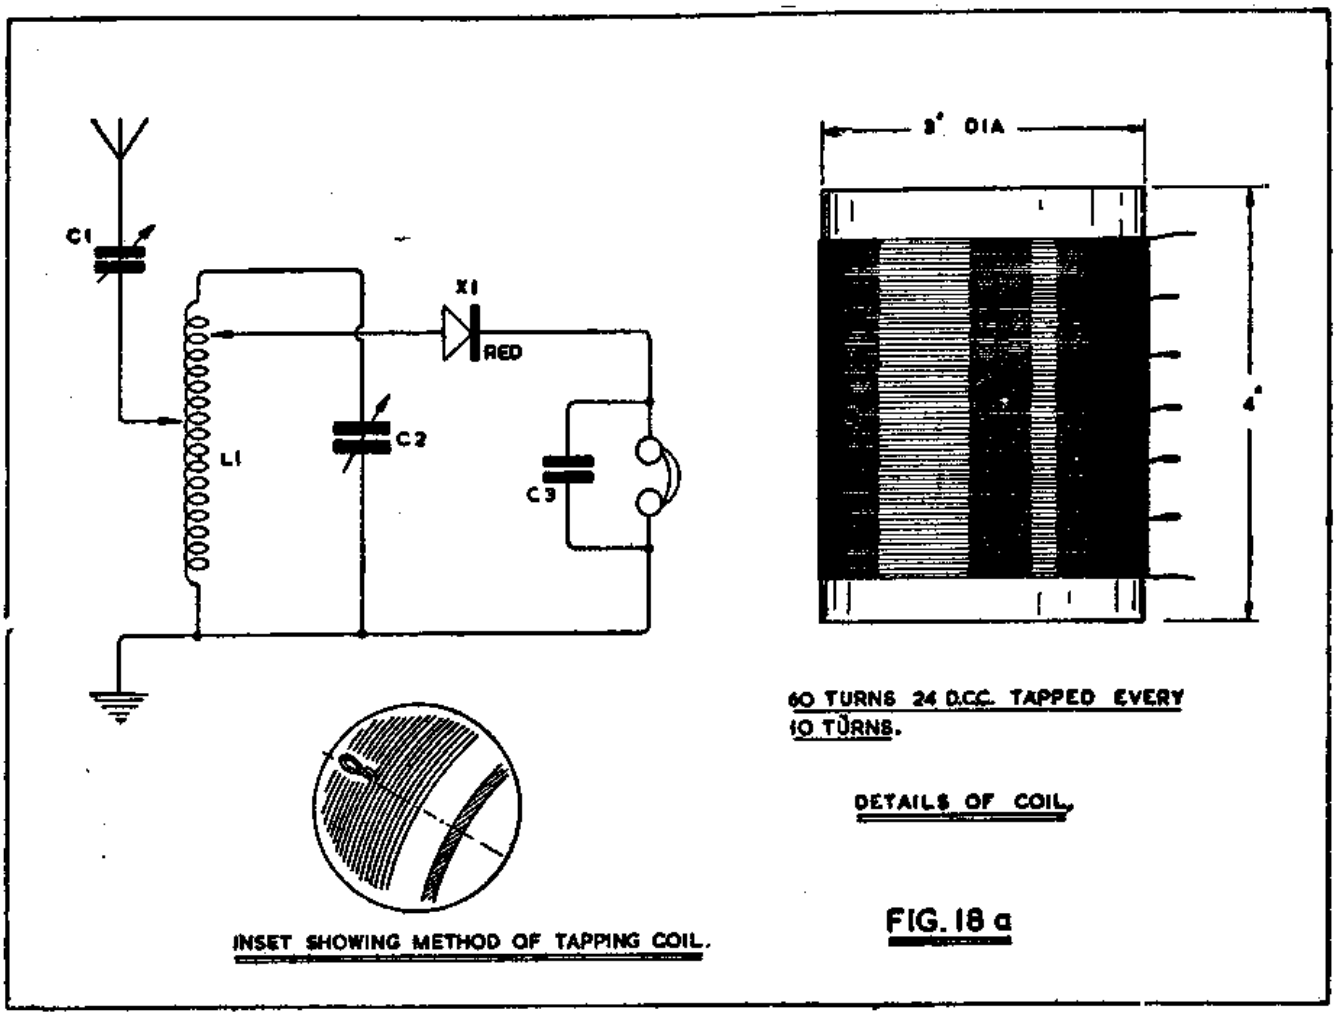
3

The design shown in Fig. 18a and 18b is more flexible than either of the preceding sets. That is, it can be varied to suit local conditions to a greater extent than the first two sets. This is made possible by the large number of taps provided on the coil.

You will notice that in this instance the coil is home-constructed on a cardboard former and is much larger than commercially produced coils. Coils wound in this manner are called **solenoids**, the turns are wound on side by side; in this case to a depth of some three inches. The diameter of the coil is made purposely large so as to obtain high efficiency. Modern commercial coils are invariably wave-wound and quite often are litzendraht which is the German for litz wire. This wire is made up of a number of strands of fine copper wire, each strand is enamelled to insulate it from the others, the whole is then silk covered. Litzendraht is more efficient than solid copper wire, and by using this and wave-winding, manufacturers can produce an efficient coil which is also small. Unfortunately wave-wound coils cannot be produced without a complex winding machine and home-constructed coils must take the solenoid form. It would be possible to use litzendraht but it is not easy to obtain by the reel, it is most expensive, and is difficult to handle. This last point is because at termination points, each strand must be cleaned of its enamel before a joint is made, and if one strand is broken, its advantage over plain copper wire is lost. How-



ever, by using a former of reasonably large dimensions an efficient coil can be produced cheaply using ordinary copper wire.

The wire must be firmly secured at the start and finish of the windings. Pierce three small holes about ¼" apart ½" from the end of the former. Pass the wire through the first from the outside, return it through the second and pass it back again through the third. Leave some 6" of wire at the end to make off the connection. It will now be possible to wind the turns on tightly without wire slipping.

Count on ten turns and make a loop 1" long. The method of preparing loops is shown in Fig. 18a, loops or taps should always be made in this manner, never by baring the wire and soldering a further length of wire to it. Carry on with the winding, making off the taps every ten turns as directed until the coil is complete.

Construction is carried out on a wooden base-board and front panel. Secure the coil to the base-board as shown on Fig. 18b, mount the remaining components and proceed with the wiring.

When testing out, it will be found that the further the aerial is tapped down the coil towards the earth end, the greater the selectivity. A position should be found which permits separation of local stations without excessive loss of sensitivity.

The crystal tap is adjusted for best results and different settings of C1 tried out, when choosing the best position for the aerial tap.

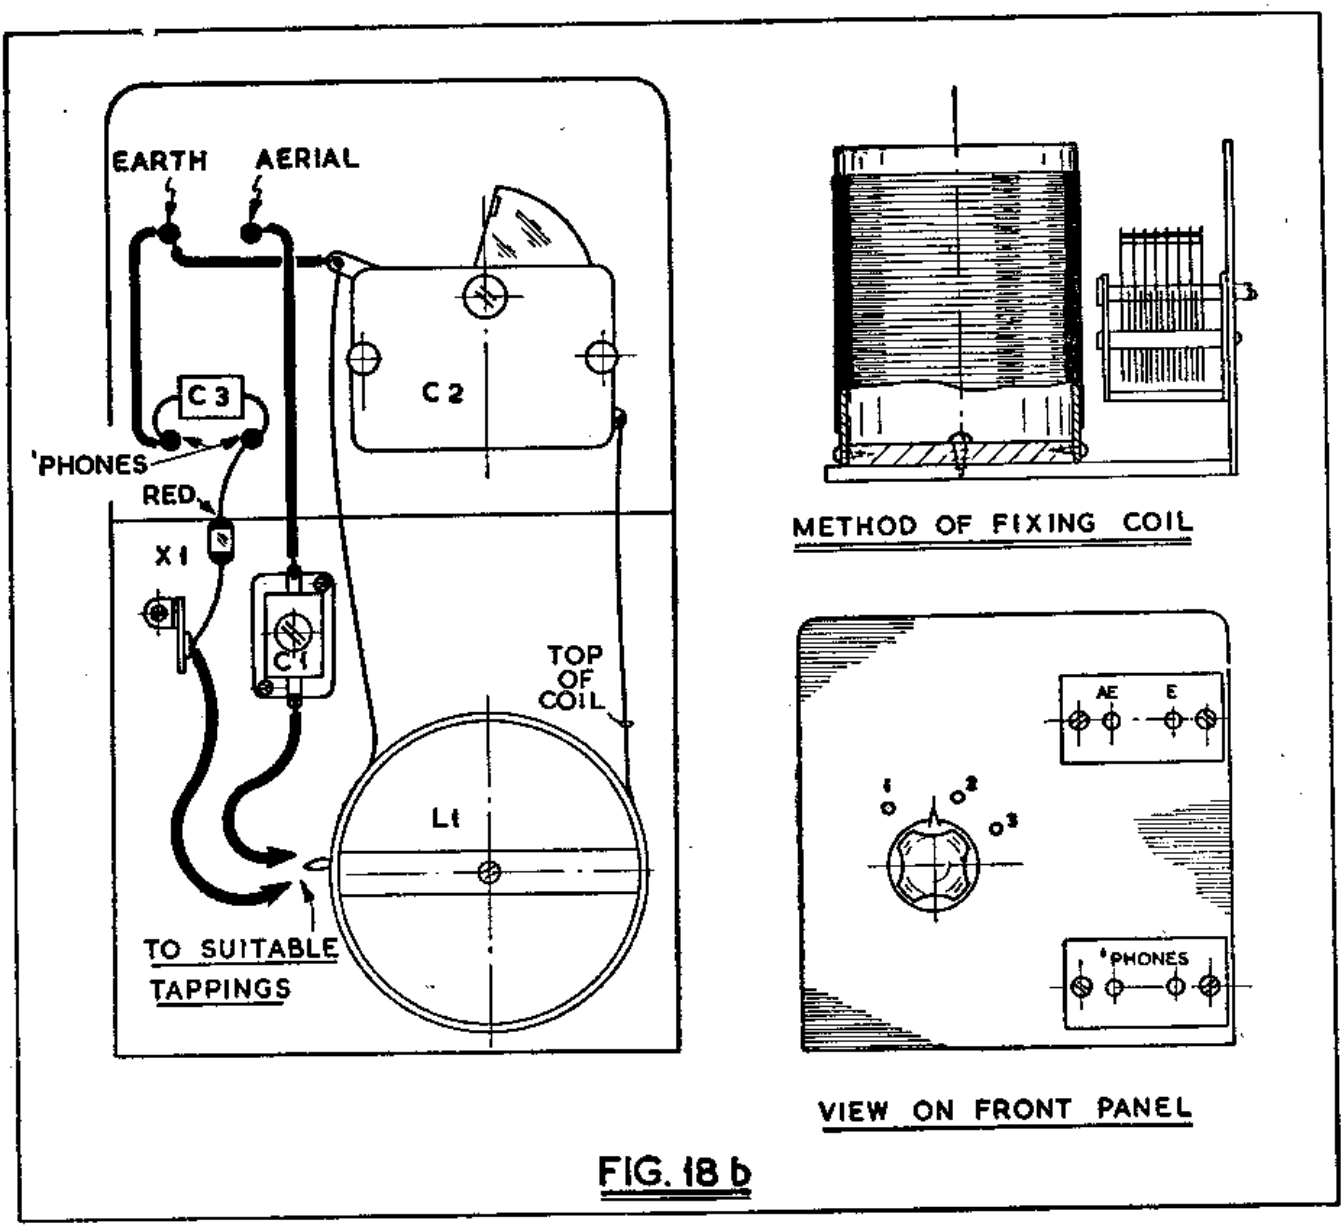

FIG. 18 b

4

A most unusual design is reproduced in Fig. 19a.

It first appeared in America about three years ago, and it certainly does offer some advantage over more conventional sets. The tuning circuits are duplicated and two crystals are used, so the circuit may be described as a full-wave receiver. Signals received will certainly be louder than with simple sets, but care must be taken with the coil winding, as with the other receivers using home-made coils, otherwise results will be disappointing. Be very careful to ensure that all three windings are in the same direction, this is very important.

The distance between each winding should be ¼". After the coil has been wound it is a good plan to warm it before a fire and paint the windings with "Durafix." Heating the coils makes the "Durafix" run freely. This substance sets quite hard and there will be no risk of the windings loosening. A small quantity of enamelled wire will cover the requirements of this coil, a 2 oz. reel will provide more than sufficient.

Before wiring in the germanium crystals, examine them carefully, note that one end is coloured red or in some cases marked with a positive sign thus +. You will notice, the sign is the same as the addition symbol used in arithmetic.

It is essential that both the red or positive ends are connected together, note that this is clearly marked on Fig. 19b. The receiver cannot work if

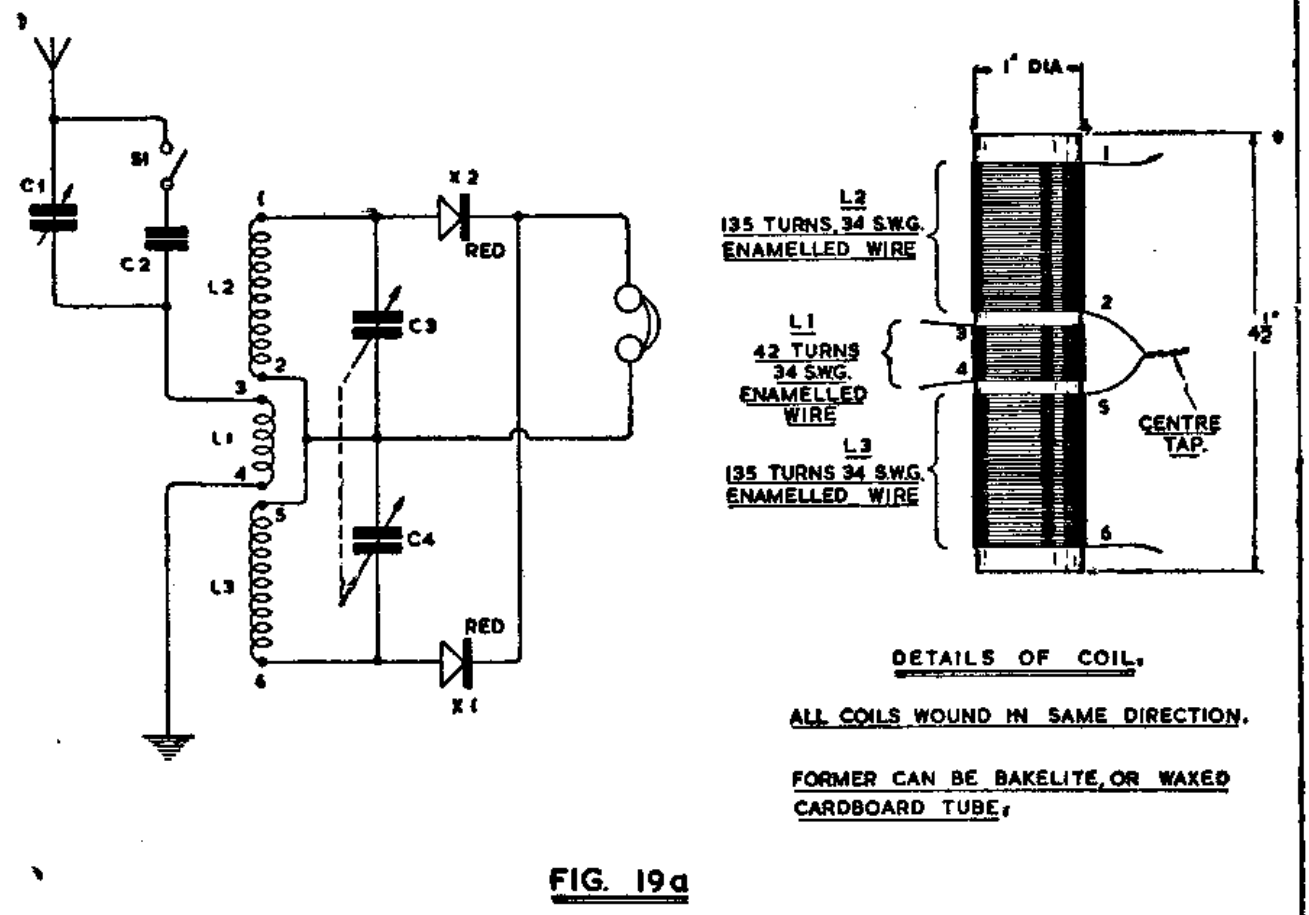

FIG. 19a

one of the crystals is connected the reverse way round.

A baseboard and panel form of assembly is used for this set which looks quite attractive if housed in a small polished cabinet. Dimensions are not at all critical but Fig. 19b gives a general idea of the layout that should be used. To avoid any unnecessary losses the coil should be mounted on perspex.

Obtain two strips of perspex 5½" long by ½" wide, drill fixing holes at both ends of each strip. It is best to clamp the two together when drilling these holes. Place one strip on the board in position, then put the coil and remaining strip over the first one and screw down. The coil will be clamped neatly and rigidly into position.

Twin socket bakelite strips are used to carry the aerial/earth and 'phone connections, if desired terminals mounted on pieces of bakelite could be used. These socket strips can be purchased from most shops selling components. If feet are not provided, drill two holes and screw into the edge of the base-board. Tag-strips are used to anchor some of the wires from the coil, and the germanium crystals. These also can be purchased for a few pence. At least two tags are necessary on one, and three on the other, though if the strips have more tags than required it is of no consequence. C3-C4, the ganged tuning capacitors have trimmers fitted, this should be stipulated when purchasing, and when first operating the set these small trimming capacitances are set about half-way. The idea of these trimmers is, that they compensate for any difference between the self-capacity of the tuning coils. With the switch S.1 open, that is in the OFF position, tune

in a station at the high-frequency end of the band, that is with the vanes of C3-C4 towards the disengaged position. Adjust C1 for maximum volume, without interference from other stations. Now adjust the trimmers for loudest headphone strength. It may be necessary to run over the adjustments several times for best results. Once they are correctly set, the trimmers require no further adjustment. The tuning coil covers the M.W. band, 1500 kc/s. to 600 kc/s., as the capacitor C3-C4 is advanced and the vanes start to mesh, the frequency to which the receiver tunes **decreases** so that with the vanes disengaged the set is tuned to 1500 kc/s. approximately and at full mesh, 600 kc/s. Switch S1 is used as follows, for stations **lower** in frequency than 850 kc/s it should be in the ON position with the contact closed, but for stations **higher** in frequency, it is in the OFF position. As an example both the London Home Service and London Light Programme transmitters on the M.W. band operate at a higher frequency than 850 kc/s. If any doubt exists as to the operating frequency of a given station, reference should be made to the Radio Times which quotes both wave-lengths and frequency. If you know the wave-length in metres, it is simple to find the frequency. Divide 300,000 by the wave-length in metres, the dividend equals the frequency in kilocycles, i.e., 300,000 ÷ 300 metres = 1,000 kc/s. In the same way, dividing 300,000 by the frequency in kilocycles will produce the wave-length in metres.

To use the receiver, tune in the signal by C3-C4, adjust C1 for maximum volume without allowing stations to overlap.

Components List, Fig. 19a

5

Whenever crystal sets are discussed, constructors are apt to think in terms of medium-wave reception. When you consider that at least 98% of published circuits are designed for this band (sometimes with the long-wave band thrown in as an afterthought) it is understandable. However, if you can provide a good outdoor aerial (and an equally good earth) there is a lot of fun to be had listening to the short-wave bands. This receiver is designed specially for short-wave reception.

A metal chassis is used for construction, these can be obtained ready made in aluminium from most good supply houses. It can be quite small and on the original model a 6″ x 4″ was used. Low loss components are used so as to obtain greatest efficiency on the short wave bands. The coil is a commercial product which plugs into a 4-pin base. Best results were obtained on the 3mc/s to 7mc/s band though coils covering other bands are available.

Note that the tuning capacitor C1 is smaller than normally used and has a maximum capacitance of 140pF.

Coil type 706/R covers the 3mc/s to 7mc/s band, but the set is equally satisfactory on the M.W. band, and to cover this coil type 706P should be used. This coil has an iron dustcore which can be adjusted to make the coil cover the required band. The effect of the core is as if turns were being added or removed from an ordinary coil. When dealing with the short waves it is customary to refer to the frequencies in terms of mega-cycles (mc/s) rather than kilo-cycles. One mega-cycle is equivalent to 1000 kilo-cycles, that is 1,000,000 cycles.

Layout and wiring can be clearly followed from Fig. 20b and a theoretical diagram is shown in Fig. 20a. Care should be taken when arranging a mounting for the aerial terminal. The best plan is to cut a 1″ hole in the chassis, mount the aerial terminal on a piece of perspex and screw into the chassis. This avoids any unnecessary losses between aerial and chassis. The earth terminal is screwed directly into the chassis.

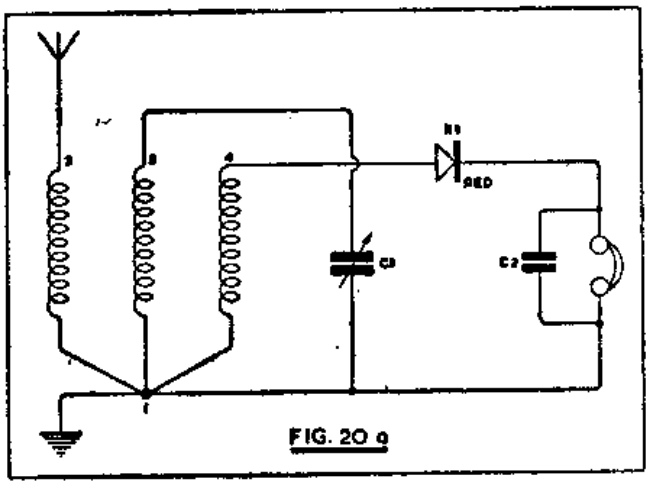

FIG. 20 a

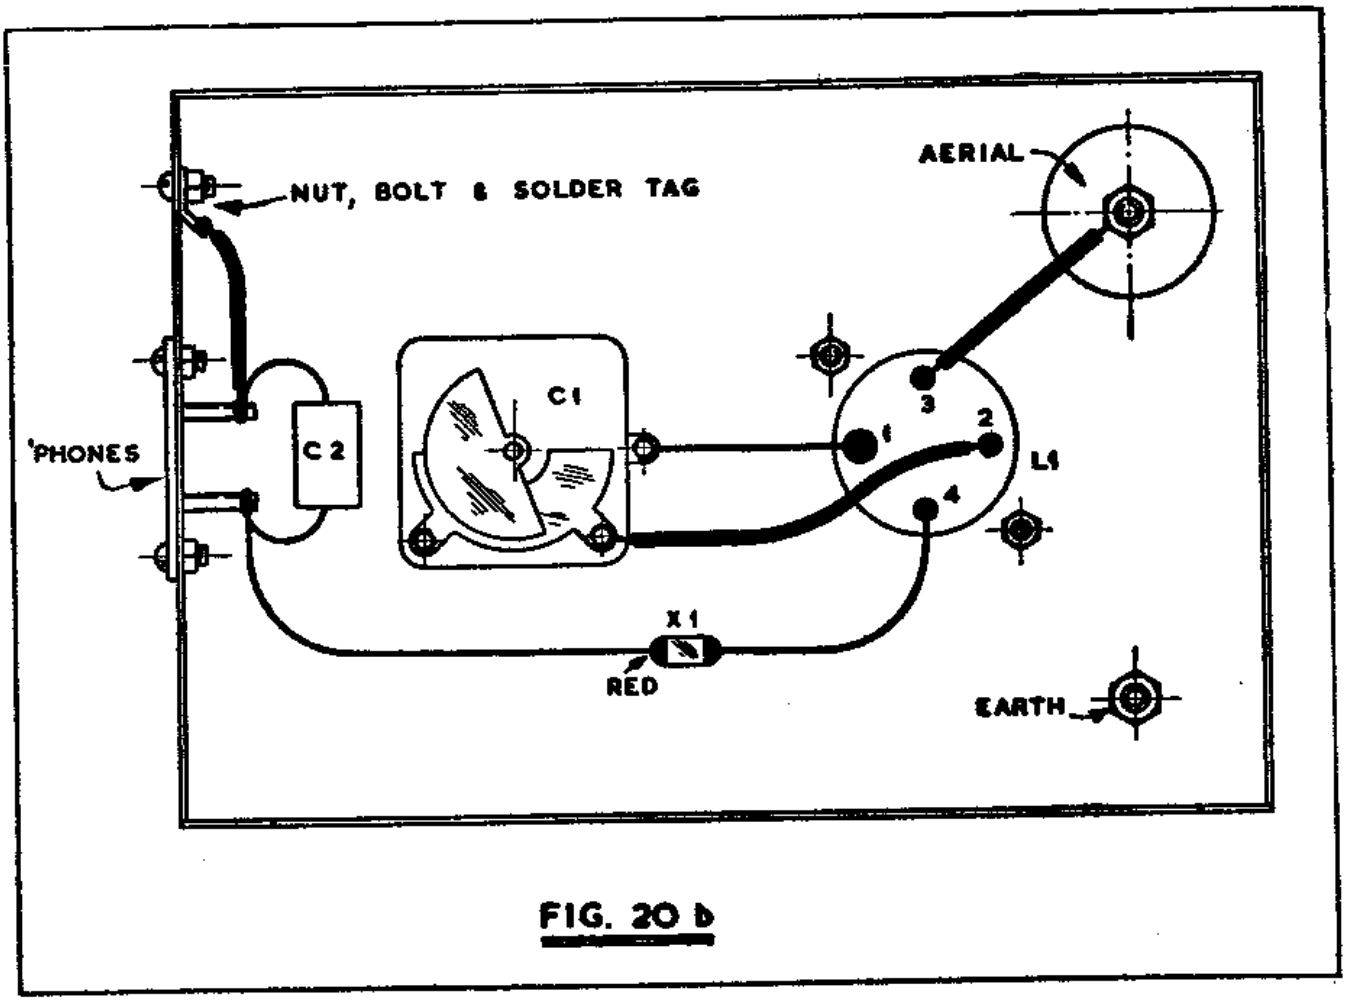

FIG. 20 b

Wiring as shown in Fig. 20a is likely to give the best results, but other arrangements are possible and to get the best out of the set they should be tried.

Refer to Fig. 20a. The aerial is connected to pin 3 on L1, C1 to pin 2 and X1 the crystal to pin 4. If you have a long aerial try this combination—Aerial to pin 4, C1 to pin 2, and the crystal to pin 3. Connections to pin 1 are not altered. In a few cases the following arrangement may prove best. Crystal **and** C1 to pin 2, aerial to pin 3, pin 4 left free and again pin 1 is unaltered.

Tuning on the short-wave bands is more critical than on the medium waves so tune very slowly over the band and remember signal strength is likely to vary from day to day.

Fig. 21a-b is yet another design from America and appeared in Radio Craft some years ago, designed by Mr. W. J. Spain. The original used a silicon crystal which preceded the development of the germanium. Results are certainly very good though of course on the model built here, a germanium crystal was used. Selectivity can be adjusted to suit all conditions and even at short distances from local stations. Good volume can be obtained without the programmes overlapping. Home made coils are used and for best results a 75′ outdoor aerial is desirable.

Baseboard and panel construction is used, which can conveniently be housed in a small wooden cabinet.

Operation is a little more complicated than some of the other designs, but the results certainly merit the extra trouble taken. As with the other receivers much of the success obtainable is due to the coils and these must be carefully made otherwise results will be disappointing.

Layout and wiring can be followed quite easily from Fig. 21b and requires no special comment.

First make the coils. L1 is a tapped coil, the taps should be made in the same way as shown in Fig. 18b. It consists of 90 turns of 22 D.C.C. (double cotton covered) copper wire tapped at the following number of turns, 5, 10, 15, 25, 30, 40, 50, 60, 70 and 80. The former used has a diameter of 2". L2 is also wound on a 2" diameter former, this coil however is not tapped, it consists of 110 turns of 38 D.C.C. or enamelled copper wire. Great care must be taken when handling this wire, it is quite fine and in the hands of the inexperienced will easily break.

After wiring has been carried out the set can be put into operation.

Selectivity is controlled by S2, in position B tuning is broad but in position A it can be quite sharp.

When searching for a station switch S2 to B. Tune the station and switch S2 to A. The frequency range is controlled by the position of the tap on L1, a good plan is to start with the 5 turn tap on L1.

FIG. 21 b

Keep S1 open and C1 for tuning, adjusting the tap on L1 for best results. Very powerful signals are best brought in with S1 closed. When using C1 and adjusting the taps on L1, switch S2 is kept in the A position.

It will be found that C2 acts as a fine control on C1. One division of the tuning dial on C1 is roughly equal to a movement of 20 divisions on C2.

Note that the coils are mounted at right angles to one another and that in this instance wood has been used as far as possible, an aluminium or other metal chassis is not suitable.

7

A very useful receiver for both medium and long-wave reception is possible with the circuit of Fig. 22a-b. A home-made coil is used. On the original a 1¼" diameter former was used but in fact this is not very critical and a 1½" former could be used. An interesting point is the construction of the long-wave coil section. Solenoid coils as used for the medium wave-band are not efficient if the length is too great relative to the diameter. Now as the long-wave section has 300 turns, if wound as a solenoid the winding length would be very great and a lot of efficiency would be lost. To overcome the difficulty the coil is pile wound. If the whole coil were to be wound in one pile it would still be inefficient because of the capacity formed in the winding, but by dividing it into five sections a coil of reasonable efficiency results. The same remarks concerning winding apply to this coil as to all the others in

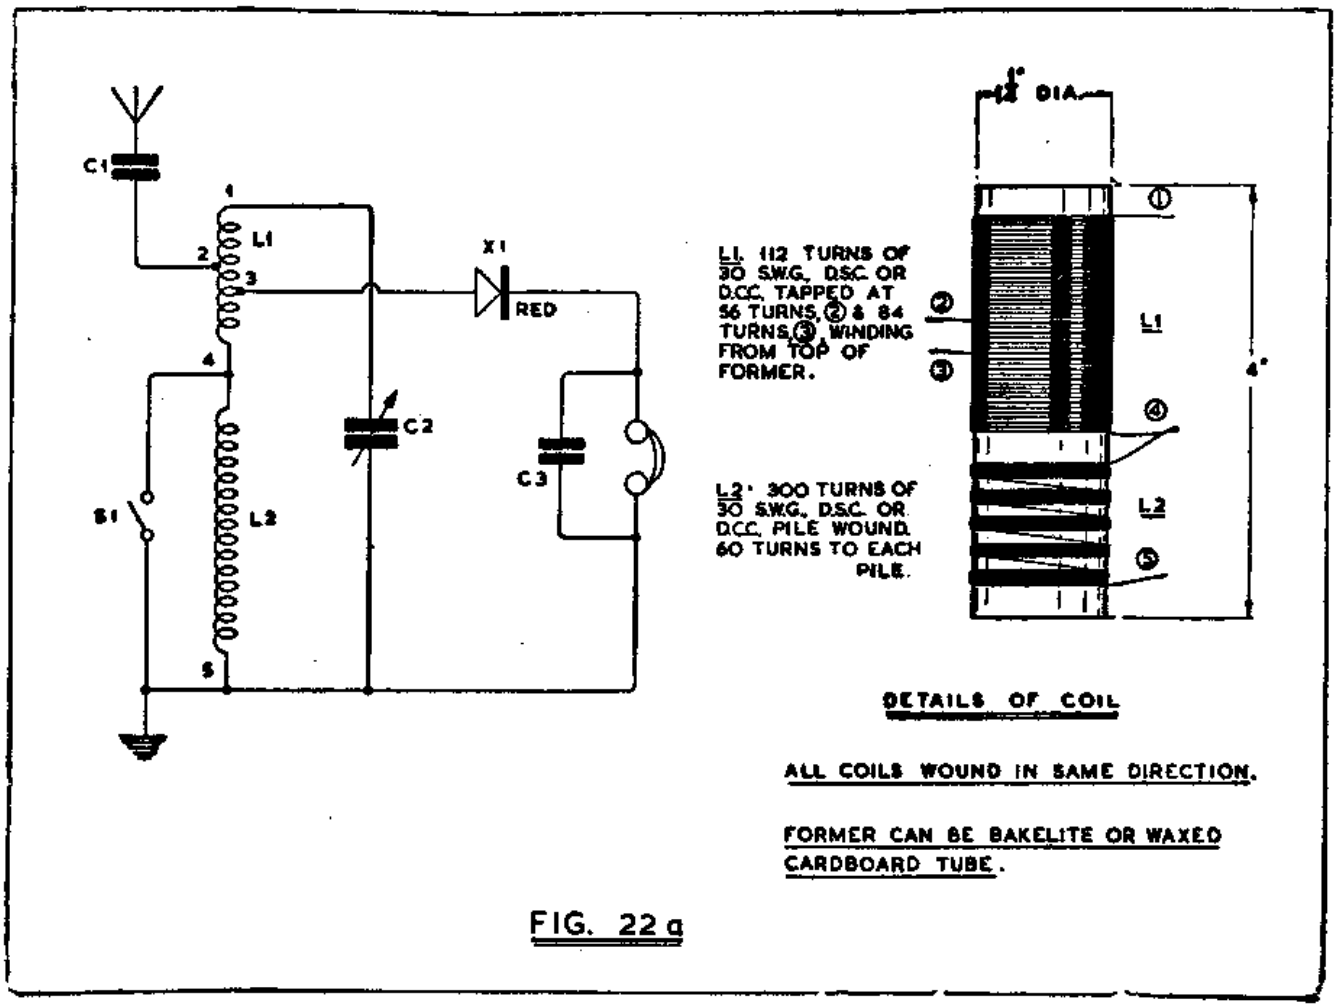

FIG. 22 a

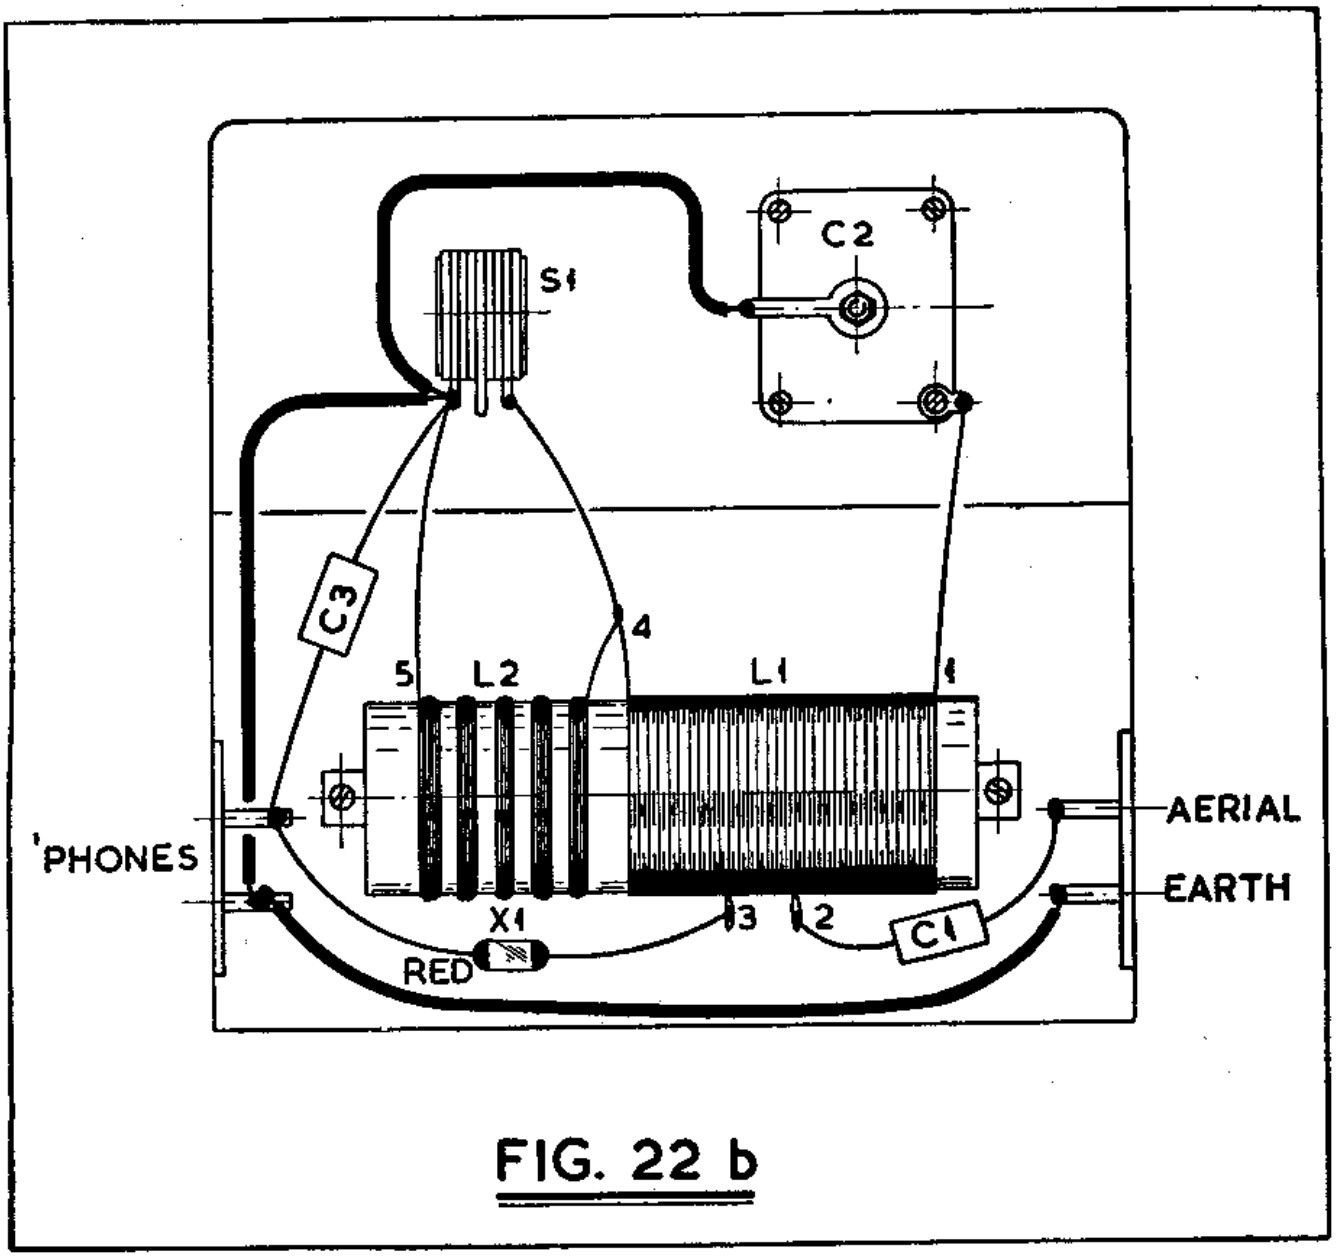

FIG. 22 b

this book, and readers should not, by this time, encounter any difficulties.

The design provides good selectivity with good sensitivity, and provided the set is not required to operate within a few miles of a powerful transmitter, no trouble will be encountered from interference between adjacent stations.

A wooden base-board and front panel is best for this design, and the wiring and layout can be clearly followed from Fig. 22b. Switch S1 is open for long-wave reception and closed for the medium-wave band.

Coil mounting can be on the same principle as for the full-wave design Fig. 19a-b.

8

If you look at all the other circuits shown in this book you will find that in each case the tuning capacitor and tuning coil are in parallel, this is by no means essential and the circuit of Fig. 23a shows a series arrangement that is the tuning capacitor is between the coil and earth instead of being wired up across it. This design also appeared in **Radio Craft** a few years ago.

An interesting point is that the coil is a conversion adapted from another type of component. To make this coil you must obtain an old I.F transformer as used in superheterodyne receivers.

You will require one designed to work anywhere between 450 and 470 kc/s. Some of the

very early ones worked at 110 kcs/ but these are unsuitable.

The I.F. transformer must also be of the type tuned by an iron dust core at each end.

Dismantle the transformer, remove the parallel capacitors and mounting wires so that you are left with two coil bobbins and their former. Be very careful when un-soldering the wires from the supports because the coils are usually wound in litzendraht and must remain intact. Remove 25% (approximately) of the turns from one coil which we will call the secondary, and completely remove the iron dust slug from this coil, now cut the former in half, and mount as in Fig. 23a. Warm the coils with heat from your soldering iron or from a fire and gently slide the coils into position at the ends of the former as in Fig. 23a. The wax will set again holding the coils in their new position.

Note that the wires from the coils are connected to tags on the mountings. These are pieces of bakelite, and usually the original end pieces used on the I.F. transformer can be used.

A word about soldering litzendraht. Do not attempt to use emery paper. Prepare the end of wire by removing the outer silk covering and dip the end in methylated spirits. Ignite with a match and after about five seconds wipe with a cloth held between finger and thumb. This will quench the flame and will remove all traces of enamel from the wire. It is a good plan to experiment with the odd length of wire removed from the secondary coil. If the coils prove to be constructed of ordinary copper wire, it can of course be prepared with fine emery cloth in the normal manner.

Components List, Fig. 23a

C1 500pF variable capacitor.
X1 Germanium Crystal.

4 Plugs and sockets or terminals.

Wiring is straight forward as can be seen from Fig. 23b and requires no explanation.

Operation is as follows, selectivity is controlled by varying the distance between coils with the wing nut, and to an extent by the position of the primary iron dust core. Remember that the aerial and earth installations are as important with this set as with any other crystal receiver. No parallel capacitance appears necessary across the 'phones, the set works quite happily relying on the self-capacitance of the head-phones.

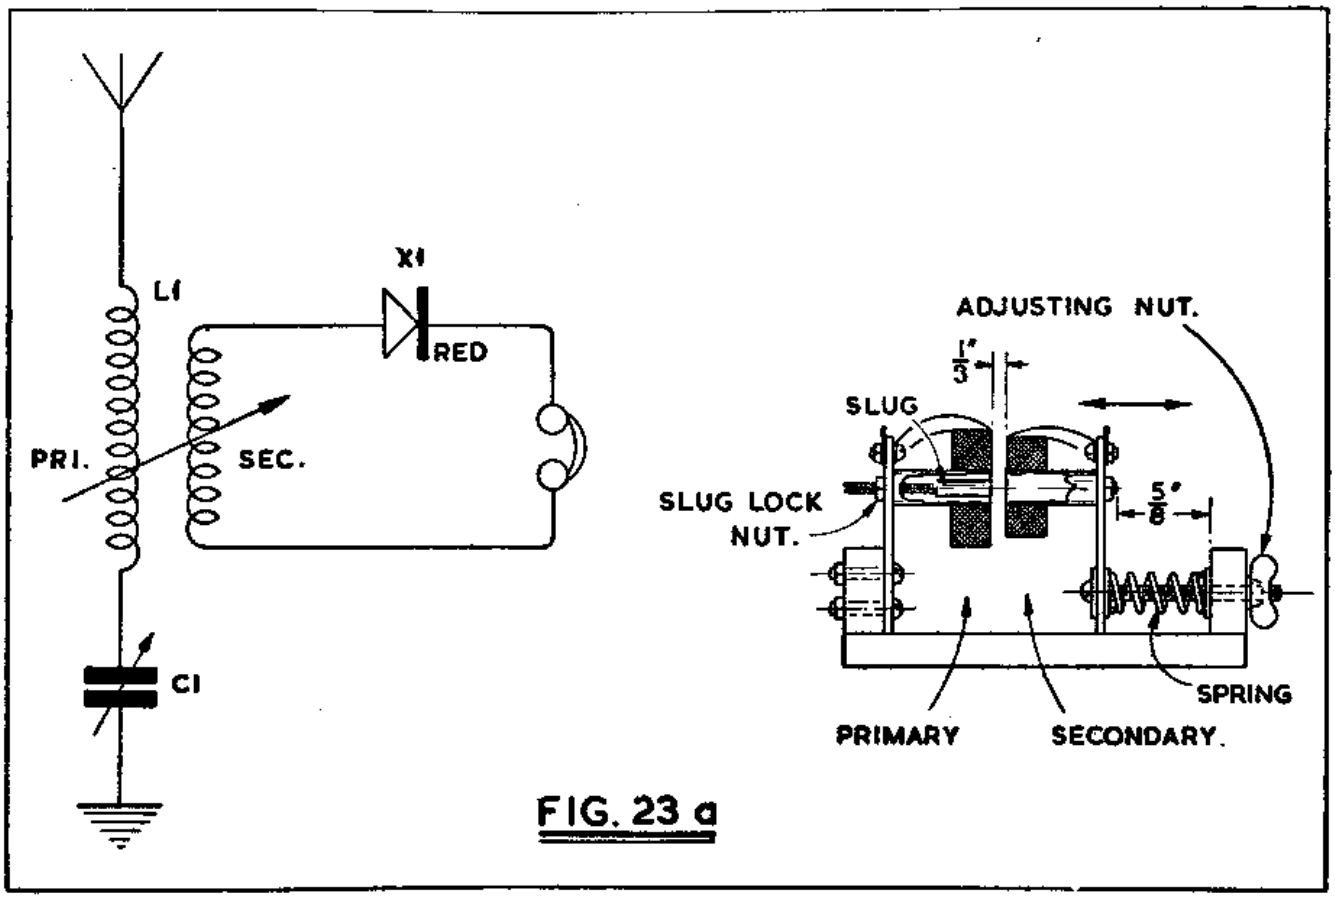

FIG. 23 a

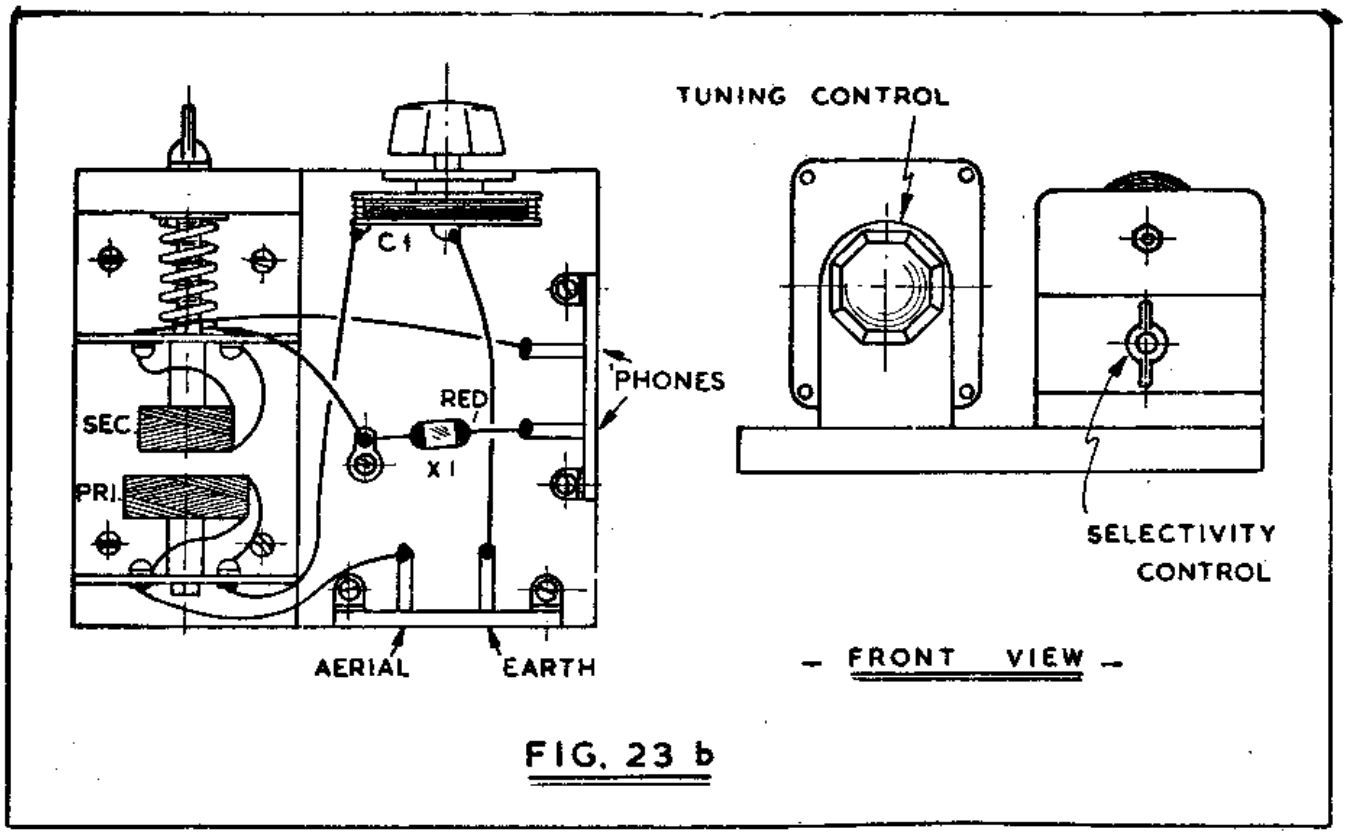

FIG. 23 b

9

So as to give a truly varied selection of circuits, some of the sets have been designed around commercial coils whilst others use coils which must be home-constructed.

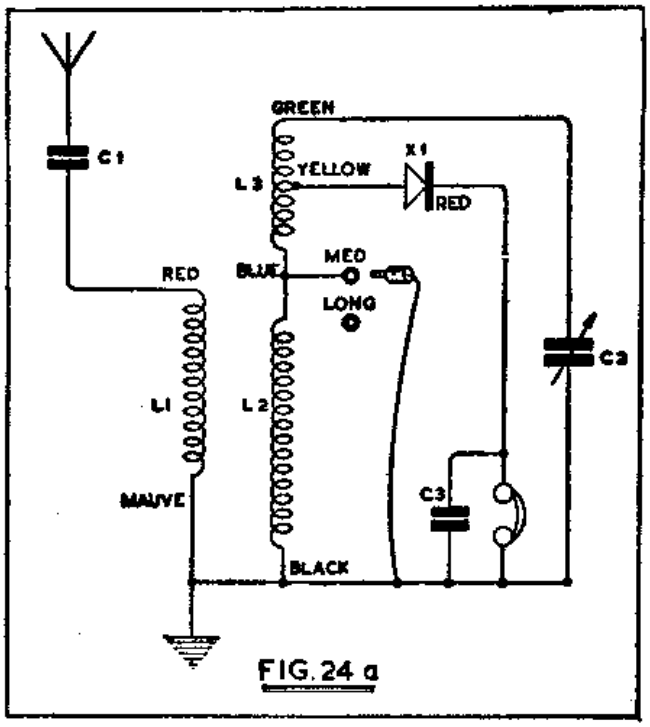

FIG. 24 a

Most enthusiasts like to build their own coils but when it is a question of something really small combined with efficiency a commercial coil is the obvious choice.

Fig. 24a-b uses a tobacco tin or a similar container just as the design shown in Fig. 16a.

This receiver however is a little more selective and is more suitable than the earlier design, if you are near a transmitter or have a very long aerial. Take great care to connect the coil according to the colours shown on the diagrams. Sockets are used for wave-changing, this cheapens the cost a little and they are just as efficient.

10

In certain cases, signals from the local transmitter are too powerful to permit a crystal set with a normal coil to be of much use. I myself live in Hertfordshire a few miles from the London transmitters, and find a more elaborate circuit is necessary. Now in radio circles it is a well-known fact that the greater the number of tuned circuits, the greater the overall selectivity. Look at Fig. 25a, you will see that the usual L and C tuning arrangements have been duplicated. This type of circuit is known as a Band-Pass Filter. There are many kinds of such filters, this particular type is an inductively-coupled filter, note that energy from the first half (L2) is conveyed to L3 by way of two small inductors L1 and L4.

Tuning is quite sharp and the "feel" of the set is quite different from that of single coil designs. A small chassis is ideal for construction.

6"x4"x2½" was used on the original, though it could have been smaller.

Fig. 25b gives the layout and wiring.

Take particular notice that L1-2-3 is mounted horizontally and at right angles to L4-5-6, this is to prevent the coupling from being too "tight" which would ruin the idea of the filter. A good aerial and earth is of course necessary. It may be found on test that the selectivity is too great

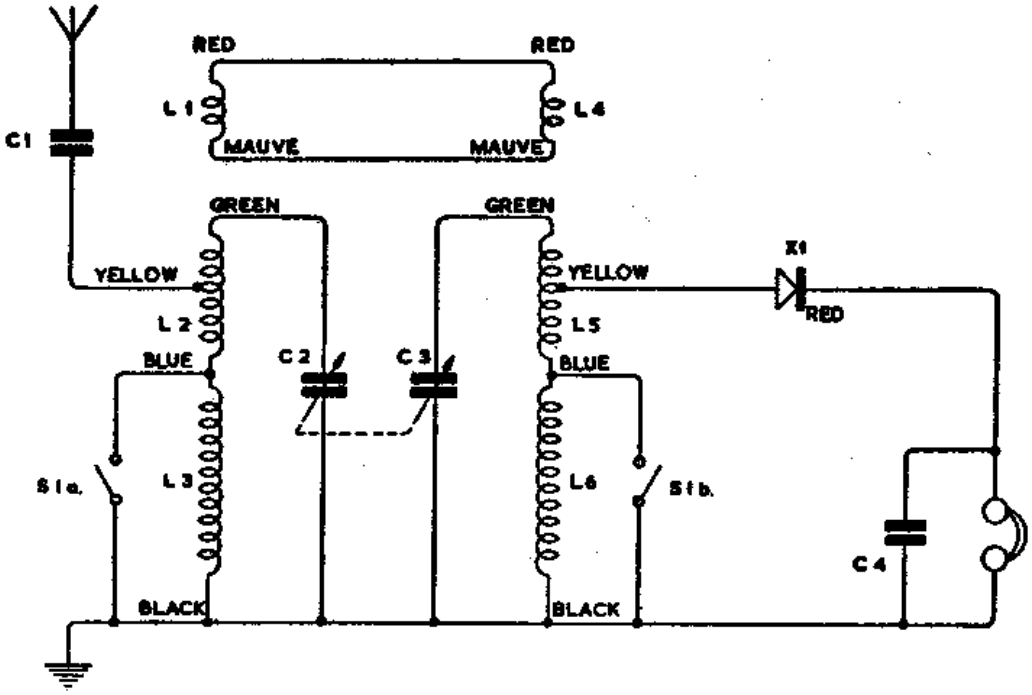

FIG. 25 a

and that volume has suffered. This can be ingeniously overcome by connecting a very small capacitance between the two Green tags on the coils. The simplest way is to connect it across the fixed vane connections on C2-C3. Values for this extra capacitance are a matter for experiment usually a value between 10pF and 47pF is sufficient. A small 50pF trimmer could be used and adjusted to suit. The ideal setting is to enable powerful adjacent stations to be received just short of overlap so that as much volume as possible is obtained.

There is one point to be observed with the ganged capacitor. It should be of the type fitted with trimmers though of course, there is no reason why you should not fit them yourself. These are to allow for differences between coils to be balanced out, and consist of a small variable capacitance across each main section.

When setting up the receiver, first set each trimmer at half way and tune in a station near the high-frequency end of the band (vanes nearly out) adjust the trimmers for maximum volume. If extra coupling capacity is added as described, try adjusting them further.

Once properly set up, no further adjustment is necessary.

FIG. 25 b

11

Another band-pass circuit is shown in Fig. 26a. This time home-made coils are used. This filter is not inductively coupled but entirely capacitive, relying on C3. As in the previous circuit it must be adjusted to give just sufficient " broadness " to the tuning to provide adequate volume without station overlap. To avoid unwanted coupling a screen is mounted between the coils, this is necessary because due to the size of the coils they would be bound to couple quite tightly without it. Such precautions were not necessary with the circuit of Fig. 25a, as the commercial coils are much smaller physically and the risk of unwanted coupling reduced.

The coils for this receiver are for medium wave reception only, this keeps the size down. Coil winding procedure has already been fully explained, and covers all the requirements of these coils. Base-board and panel construction is used, and for more accurate tuning since the coils are home-made, separate tuning capacitors are recommended. Fig. 26b gives the layout and practical wiring.

Components List, Fig. 26a

C2 500pF variable capacitor.
C3 50pF Mica trimmer.
C4 500pF variable capacitor.
C5 1000pF mica capacitor.
L1-2 See text.
X1 Germanium Crystal.
4 Terminals or plugs and sockets.

For those who do not wish to bother with these a ganged capacitor can be used, but tuning may not be as good as with separate ones. The screen mounted between the coils is of aluminium or copper and should be about 1" higher than the coils and the same length as the baseboard depth.

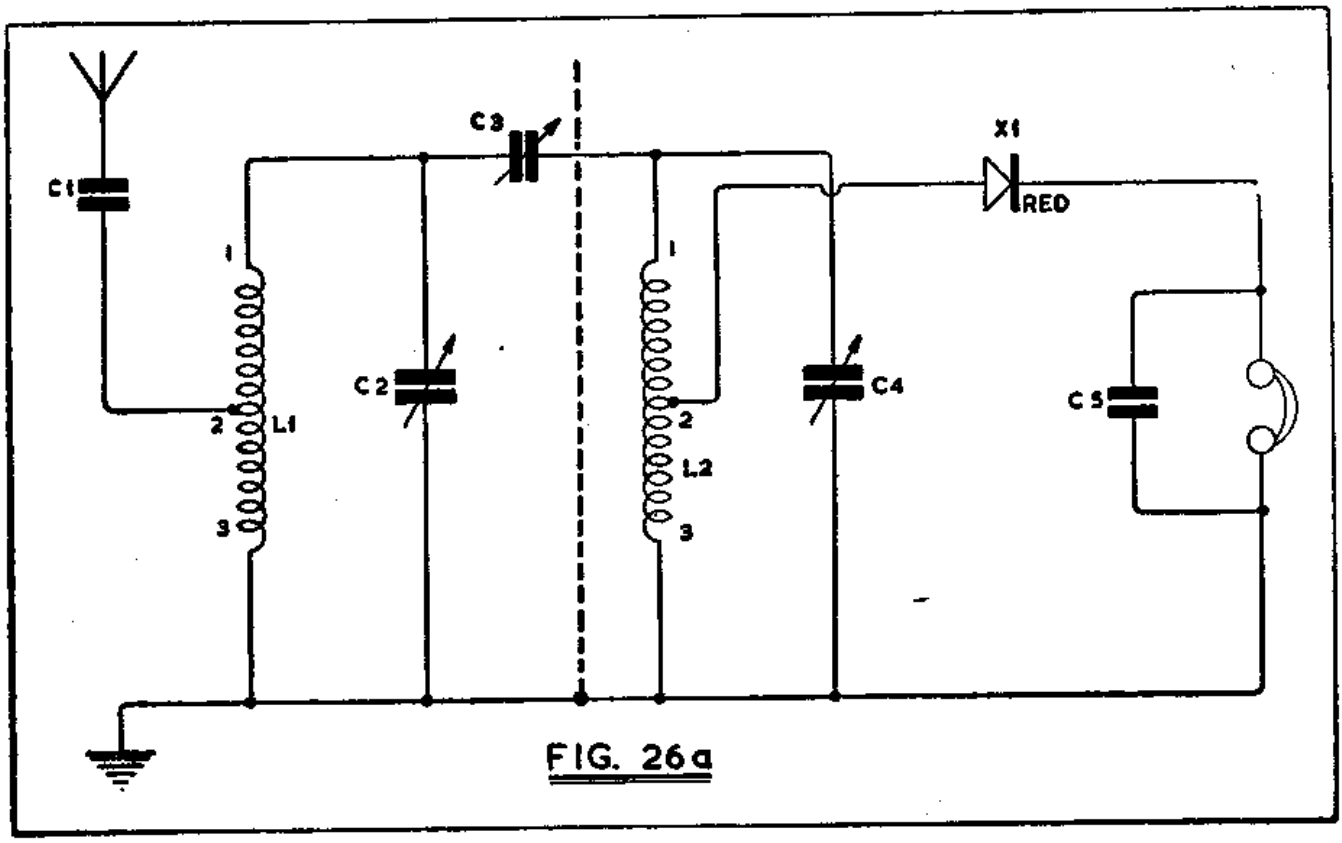

FIG. 26a

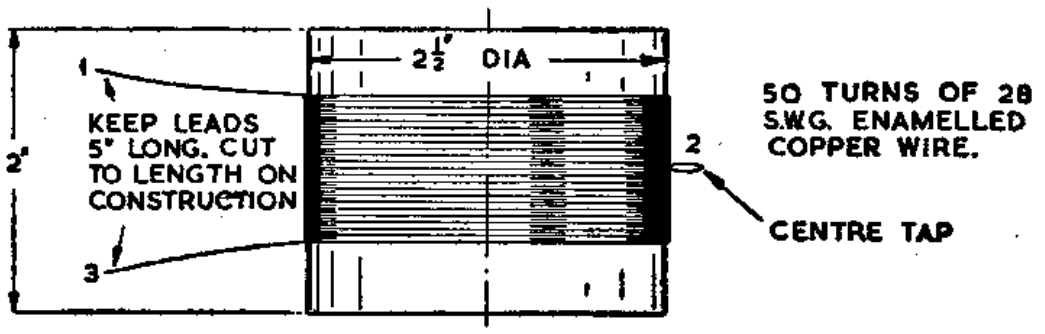

COIL DETAILS.

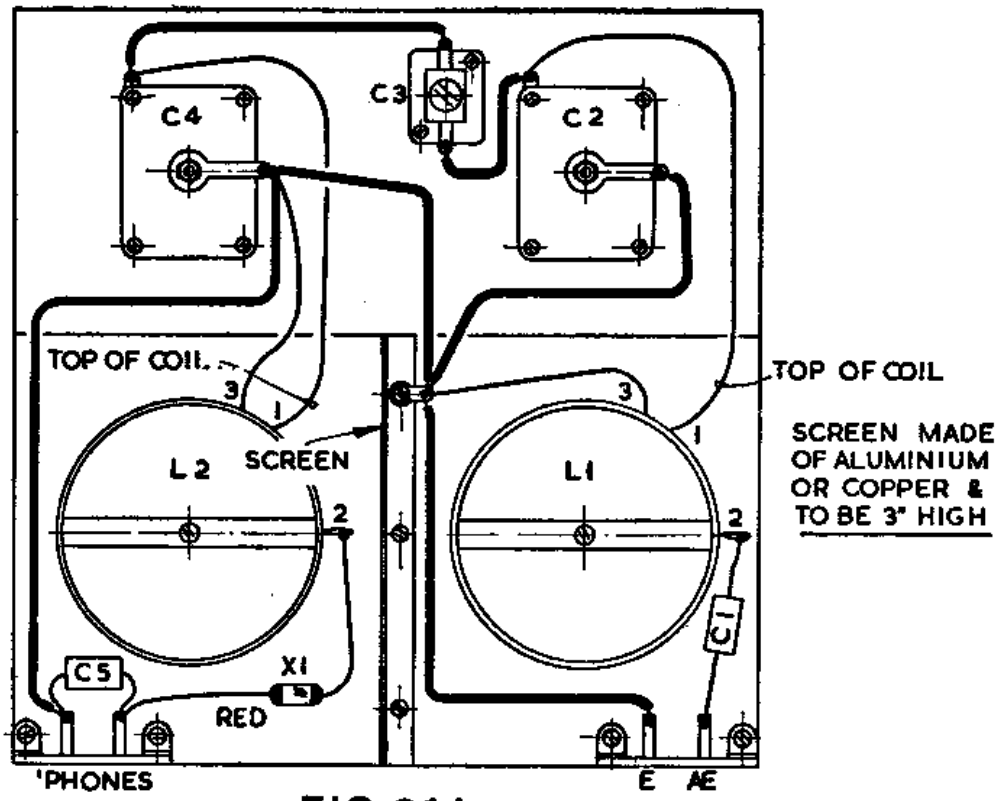

FIG. 26 b

12

Fig. 27a-b uses a band-pass filter for tuning, and the coils are home-constructed.

With this design a ganged capacitor is quite suitable as the coils tune quite accurately. It is essential that the coupling condenser C3 is **non-inductive,** there will be no difficulty in obtaining a new component of this pattern but it is as well to avoid old components which may not employ this form of construction.

Receivers using this type of filter are used to the best advantage when situated a short distance from a powerful transmitter and if selectivity is not important this particular design is not the most suitable.

Both medium-waves and long-waves are catered for: consider L1-2-3, this is the first half of the filter.

L1 is the aerial coupling coil, with S1 closed,

the medium-waves are received. This coil is inductively coupled to L2 and L3. Again with S2 open L2 and L3 combined cover the long-waves and when S2 is closed the medium waves are covered.

Tuning for this half of the filter is by means of the capacitor C1, which is one half of the ganged capacitor. A screen is erected between the two sets of coils comprising the filter, and coupling is effected by C3, an earth return for the coils is provided by R1.

L4 and L5 operated in a similar manner to L2 and L3, tuning is by means of C2, the remaining section of the ganged capacitor. You will realise that the coils must be accurately wound otherwise tuning will not remain constant between the two sections over the band.

The ganged capacitor should be fitted with trimmer capacitors when purchased so that the two circuits can be balanced.

You will have noticed that this circuit uses three sets of switch contacts. A three-pole two-way wafer switch is the best choice otherwise either two or even three separate switches are necessary. All the necessary coil details are given in the diagrams, the tap on L4 is made in the same way as shown for other coils in the manual. One other component used only on this design, is the resistor R1, its size is not important because the current flowing is so small it can be ignored.

A ½ watt rating is adequate, its precise value is not critical so that a 20% tolerance component is quite suitable.

Resistors are coded by colours and the 1000Ω type you require will bear the following sequence. At one end will be painted three coloured rings.

SYMBOLS USED IN THE CIRCUITS DESCRIBED.

FIG. 28

The first one is BROWN which represents 1, the first figure of the value, the second BLACK, this indicates the second numeral is nought, and the third colour is RED which tells us that two further ciphers or noughts are added to give the total value. From this you can see, we have 1 plus a nought equalling 10, plus two further noughts which total 1000. Some earlier types of resistor were painted differently, the whole body colour represented the first figure, one tip was coloured to represent the second figure, and a painted dot in the centre gave the number of ciphers to be added.

There are no other special points regarding construction except perhaps that if a long aerial is used, a small 100pF capacitor might be tried in the aerial lead to prevent damping the first tuned circuit.

When setting up the receiver, tune to a station the high-frequency end of the M.W. band and the trimmers for loudest volume, no other adjustments are necessary.

CONCLUSION

The twelve receivers described are representative of the best crystal set designs available to-day. Their construction will provide many hours of useful enjoyment, and the results will give lasting pleasure.

A final word about components, if no actual maker is specified, any good class component can be used. Switches, fixed and variable capacitors and crystals, are available from numerous manufacturers all of which are invariably of excellent quality. Where a particular manufacturer's product is called for, the specification should be adhered to. The commercial coils specified are freely available from most supply houses specialising in components for constructors, but in case of difficulty write to Bernards (Publishers) Ltd., The Grampians, Western Gate, London, W.6, who will, on receipt of a S.A.E. be pleased to supply the address of your nearest stockist. Coil formers are not always easy to obtain and in this case advice should be sought from Post Radio Supplies, 395, Queensbridge Road, London, E.8, who will be pleased to help in any way possible.

Build a 3-Band Shortwave Converter for Your Car

Wouldn't it be nice if you could take your shortwave radio with you in your car? Imagine tooling down the highway on your way to work, listening to the latest world news on the BBC. Or maybe tuning in a spot of upbeat Latin music to get your day started on the right foot.

You could put an inexpensive portable on the dashboard and watch it slide from one side to the other every time you make a turn. The heat of the sun, magnified through the windshield, even in winter, might ruin that radio and chances are that if it survives that, someone might steal it. Too much of a headache? There is an easier way.

We're going to show you how to build a converter for your car radio that will allow you to tune in the 49 (5950 to 6200 kHz), 31 (9500 to 10000 kHz) and 19 (15100 to 15490 kHz) meter bands without all of those hassles. We chose these bands because the probability of finding one or more of them open during any time of the day or night is good. Also, the time signals from WWV on 10000 kHz are tuneable on the 31 meter band. So we have a talking clock in our car to tell us how late we are!

How it Works

There are two controls on the converter; the bandswitch S1, and the on/off switch S2. T1 matches the car antenna's impedance to the input impedance of Q1, a dual gate mosfet. Capacitors are placed in parallel with T1's secondary by S1A. These capacitors are chosen to resonate T1 to the band we wish to tune on the car radio.

Q1 is the mixer. Shortwave band frequencies are present on gate #1, while a fixed H.F. frequency from oscillator Q2 is present on gate #2. At the drain of the mixer are 4 signals: the 2 original ones on gates 1 and 2, their sum, and their difference. The difference frequency will fall in the tuning range of the AM car radio.

Q2 is a Pierce crystal oscillator. Two capacitors (designated Cfb) provide feedback to sustain oscillation. S1B selects a crystal to correspond to the band selected by S1A. The oscillator is a fundamental type, meaning it's output is the same frequency as the crystal.

S2 is a DPDT slide switch. One pole switches 12v DC to the converter during use, the other pole switches the converter out of the antenna line when not in use.

Choosing Crystals

The builder is given wide latitude in choosing crystals for this converter, with the hopeful result that he will be able to scrounge them up for free in the junkbox or for cheap at a swapmeet or hamfest. It makes no difference if the crystal frequency is above or below the shortwave frequency we want to receive, so long as the difference falls in the tuning range of the AM car radio.

If the crystal frequency is below the shortwave frequency, then the car radio will tune the shortwave band in the conventional manner (lowest frequency on the left, highest on the right of the slide rule scale). If the crystal frequency is above the shortwave frequency, then the car radio will tune "backwards" (highest frequency left, lowest on the right).

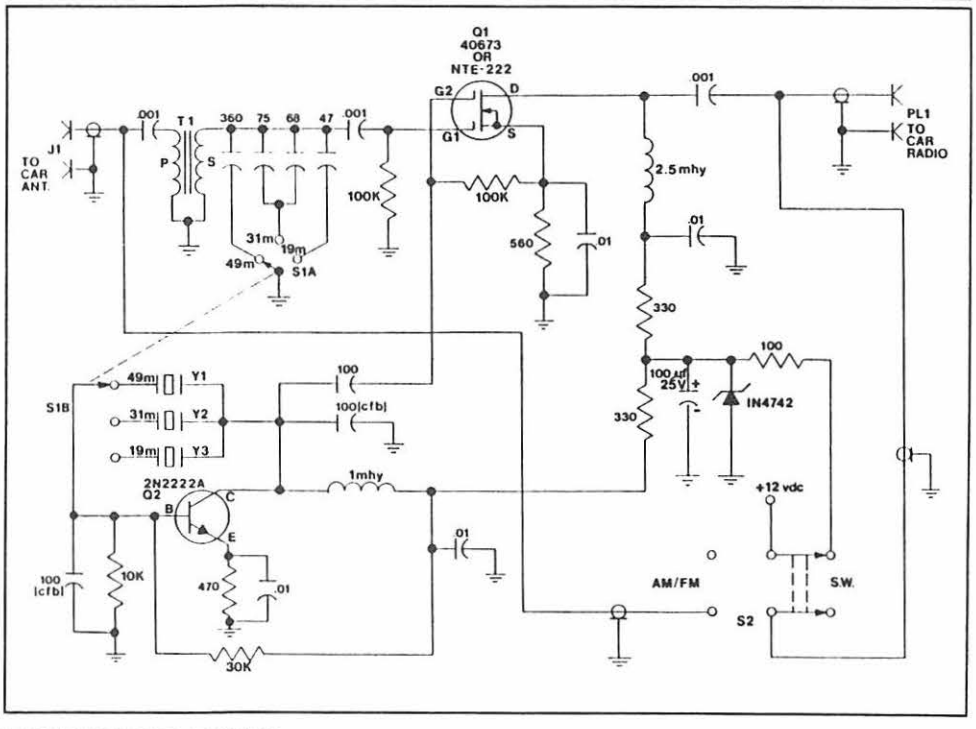
Listening enjoyment will not be affected if you choose a crystal which causes "backward" tuning. So start scrounging for crystals that will fall in the frequency ranges given in the chart below, and see how cheaply you can get by!

Construction Tips

The manner of construction is not too critical. Perfboard is recommended for the first time builder. An ambitious builder could make up a single or double sided PCB. T1 must be wound by hand; the secondary windings must use the gauge of wire specified and must be "closewound" in order for the transformer to resonate properly with the values of fixed capacitors specified in the schematic. A sketch of how the transformer should look is included with the semiconductor base diagrams.

Crystal Frequency Ranges

Xtal	Band	Band Frequency	Xtal Frequency Range
Y1	49M	5.95-6.2 MHz	4.6-5.41 MHz or 6.74-7.55 MHz
Y2	31M	9.5-10.0 MHz	8.4-8.96 MHz or 10.54-11.1 MHz
Y3	19M	15.1-15.49 MHz	13.895-14.56 MHz or 16.035-16.7



Keep all leads to S1 as short as possible. One way to do this is to mount S1 on the front panel of the box you are going to use, then mount your board directly behind S1 using screws, spacers, and nuts. (see diagram). J1 and PL1 are simply a 2 foot long car antenna coax extension cable available from Radio Shack, which is cut in half. Drill two holes in the back of the box and fit the holes with grommets, then put the two pieces of coax through the holes. The +12v power lead can also pass through one of the holes with the coax.

Be sure and use a metal box for the enclosure, as a plastic one will allow the strong local mediumwave stations to "bleed" past the mixer and you'll never hear any shortwave stations. The fixed capacitors on S1A could be replaced by small trimmer capacitors of a slightly higher value if desired. This will increase the costs but will allow you to more exactly resonate T1 to the center of each shortwave band.

Using the Converter

First of all be advised that this project will work best with a conventional slide-rule tuned (analog) car radio. Most digital radios are pre-programmed to tune in 10 khz increments, where as shortwave stations are in 5 khz increments or on "weird" frequencies like 99770 kHz. So a digital car radio which is programmed in 10 khz increments will only allow you to hear half of what is available.

Next you need to know where on your dial you can expect to find the shortwave. To do this, subtract the frequency of each crystal you've found from the band limits of it's corresponding band. For example, say you found a crystal marked 8.65 MHz for the 31 meter band. 9.5 - 8.65 = .85, and 10.0 - 8.65 = 1.35. So you will tune the 31 meter band between 850 and 1350 on your car radio, with WWV falling on 1350.

This circuit is sensitive enough to get all the major broadcasters loud and clear with your engine on. And if you are out camping in a quiet location with your engine off, you can actually do some real DXing on your car radio using only the car's antenna!

Good luck! Any questions from constructors regarding this project will be answered if a Self-addressed, stamped envelope is enclosed.

* Hook power lead to "radio" side of fuse, or use an in-line fuse holder with a 1/4 A fuse inside.

Cigar Box Radio

BACK in the early days of radio, it was a common sight to see the entire family crowding around and taking their turn at the earphones of the latest marvel of the age—the crystal set radio. It seemed so uncanny how it was possible to get music and voices in the room from afar without the use of wires. With the advent of newer radios the crystal set slowly lost its popularity. However, it still is lots of fun to turn the pages of time back and build a simple crystal set. Anyone with but average workshop skill can easily construct such a set in an evening or two, and, if located about ten miles from a broadcasting station reception should be good.

Winding the coil. Coil tube, with its wooden center core, revolves when the handle is turned.

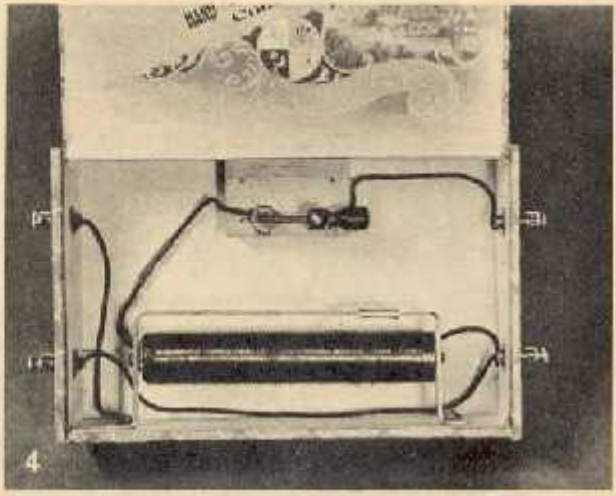
After the ends of the coil are made secure, apply a thin coat of shellac to the entire surface.

Carefully solder a wire lead to each end of the coil. Use No. 18 or 20 insulated flexible wire.

The first step is to make the tuning coil inductance that is used in the antenna circuit. Take a piece of ¾ to 1 in. diameter mailing tube or fibre tubing about 6 inches long and closely wind on a single layer of No. 26 to 28 gauge enameled wire. For winding the coil make the simple jig shown in Photo 1. The jig consists of a base board with two L-shaped metal brackets. The coil tube is set between the brackets with a screw holding one end and a piece of ⅛ in. steel rod which acts as a handle, imbedded into the other end. Both screw and handle rod are driven into a round piece of wood pressed into the tube for a center core. The wooden center is left in place and later permits mounting the finished coil permanently in the cigar box. The end of the steel rod, which forms the turning handle, is flattened where it is driven into the wood.

The start and finish of the coil are secured from unwinding by drilling a small hole at each end of the tube and passing a loop of the wire through each hole. The coil is then given a coat of thin shellac, as illustrated in Photo 2.

The next job, shown in Photo 3, is to



Arrangement of parts within the cigar box. Note the coil mount, slider, and crystal detector.

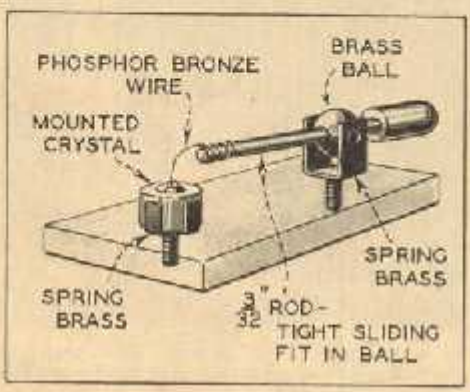
BY HAROLD P. STRAND

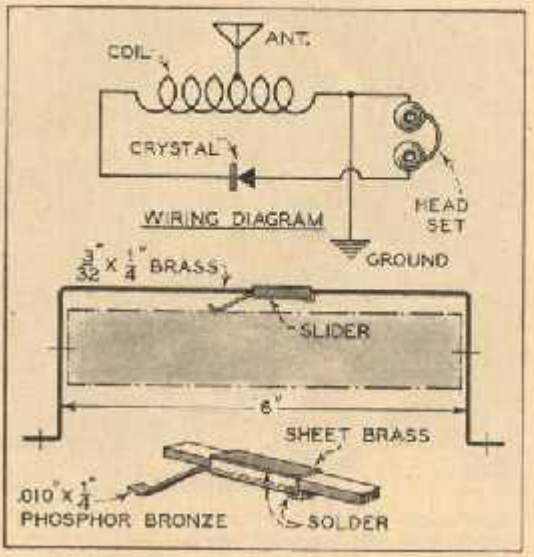
solder a piece of No. 18 or 20 insulated flexible wire to the start and finish of the coil to act as leads. Each wire lead is made secure by inserting the end through the hole drilled for the winding ends.

Next mount the coil to the front side of the box with short bolts inserted through a combination support and slider arrangement, as pictured in Photo 4. The support is merely a strip of $\frac{1}{4} \times \frac{3}{16}$ in. brass bent to fit the coil. The slider, built up from sheet brass, slides freely on the strip. Clean the coil over which the slider rides with fine sandpaper, down to the copper, so a good contact will be made with every turn. Wood screws are used at each end of the coil to hold it in place.

The detector is a common mounted galena crystal and an adjustable arm with a "cat whisker," obtainable from any radio or electrical store. At each end of the box binding posts are fitted. The upper one at the left side is for the antenna connection and the lower one for the ground. The right hand terminals are for the phones. The antenna comes in and connects to the brass slider at its bottom foot. The ground connects to one phone terminal and also to one end of the coil. The other end of the coil goes to the crystal and the detector arm to the remaining phone terminal.

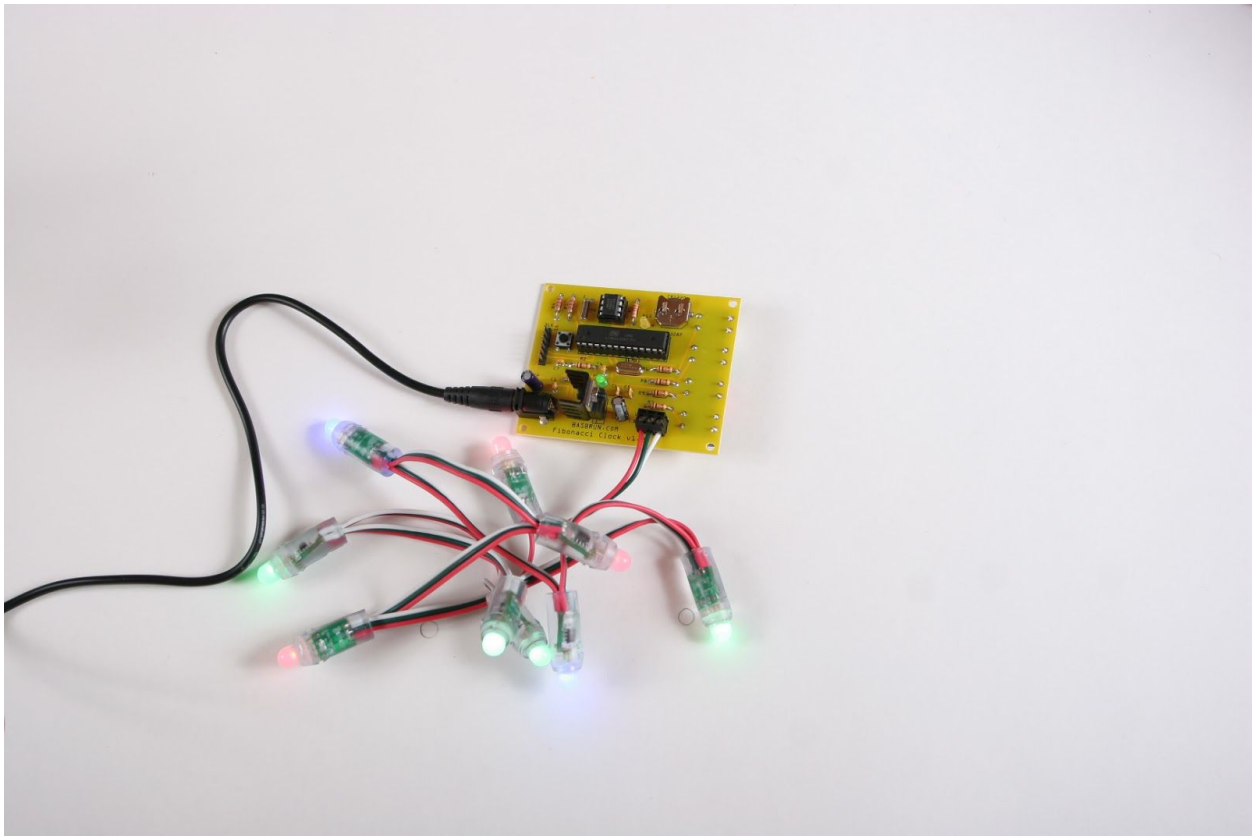
For best results a long outside antenna of about 75-100 ft. long is recommended. The earphones should be sensitive and wound to a fairly high resistance, such as 2000 ohms. Adjustment is provided by the sliding contact which varies the tuning inductance. It should be possible to get several local stations on different spots on the coil, but selectivity will be only fair so in some cases interference may be experienced. The detector must be very carefully adjusted to find a sensitive spot by moving the cat whisker around to touch different places on the crystal.





Circuit Board Assembly Instructions

This document walk you through the assembly of the Fibonacci Clock v1.2 circuit board.



Important note for kit buyers **The color and appearance of the components may vary from one supplier to another and not match exactly the components illustrated in this document.**

The kit provided for the Kickstarter backers matches the images here with the exception of the ceramic capacitors and one electrolytic capacitor. Some notes have been added to the “Parts” section when the appearance differ.

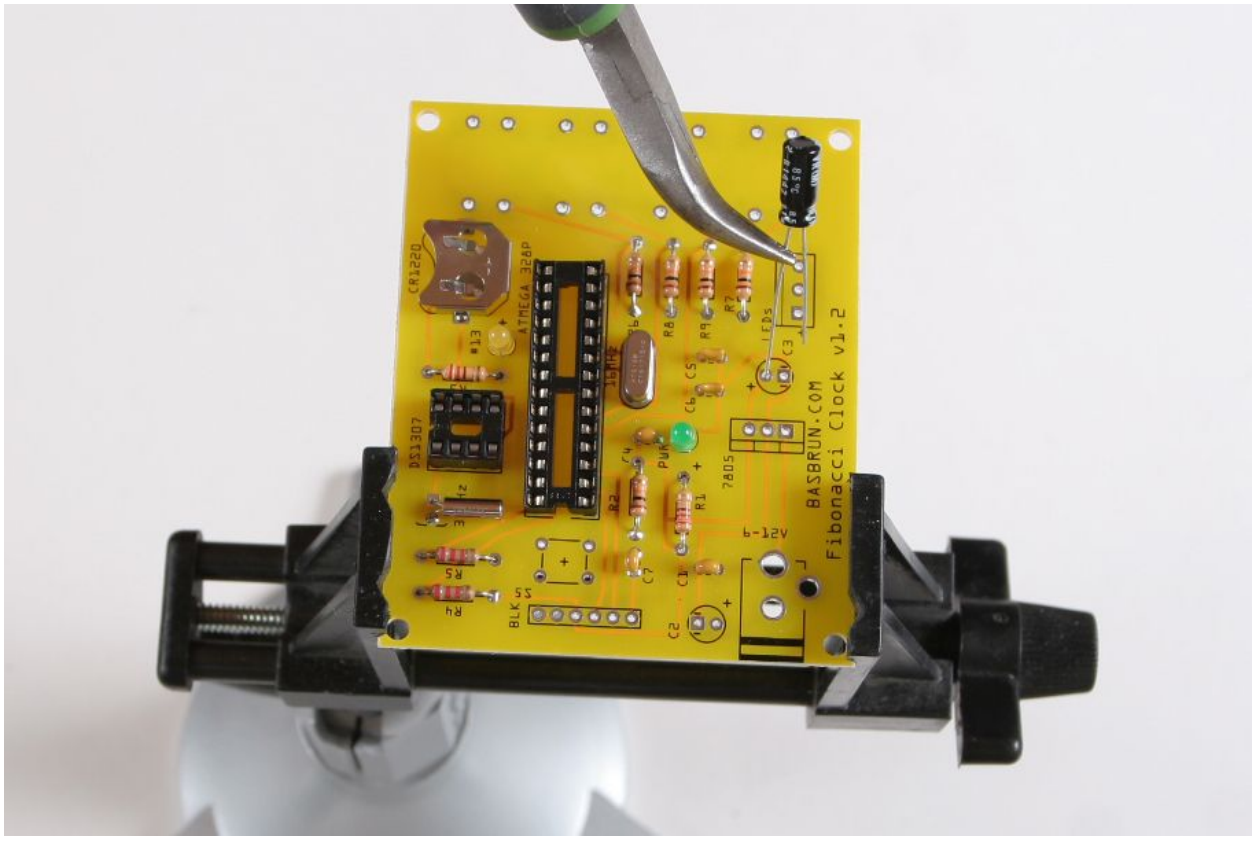
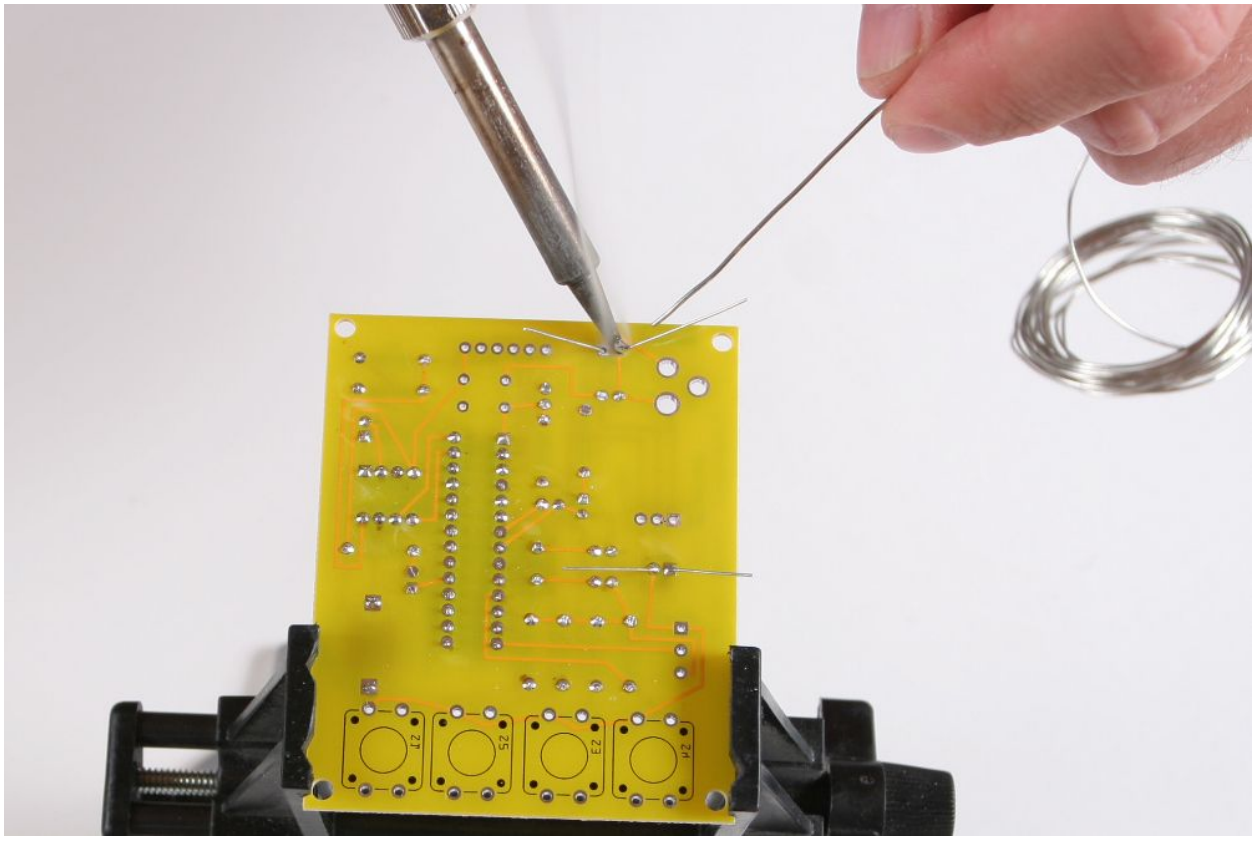
CAP ALUM 10UF 20% 25V RADIAL ***May be blue in your kit***	1	

Place the 10uF electrolytic capacitors on C3. Electrolytic capacitors are polarized, make sure to insert the long wire into the round hole marked with a (+) sign.

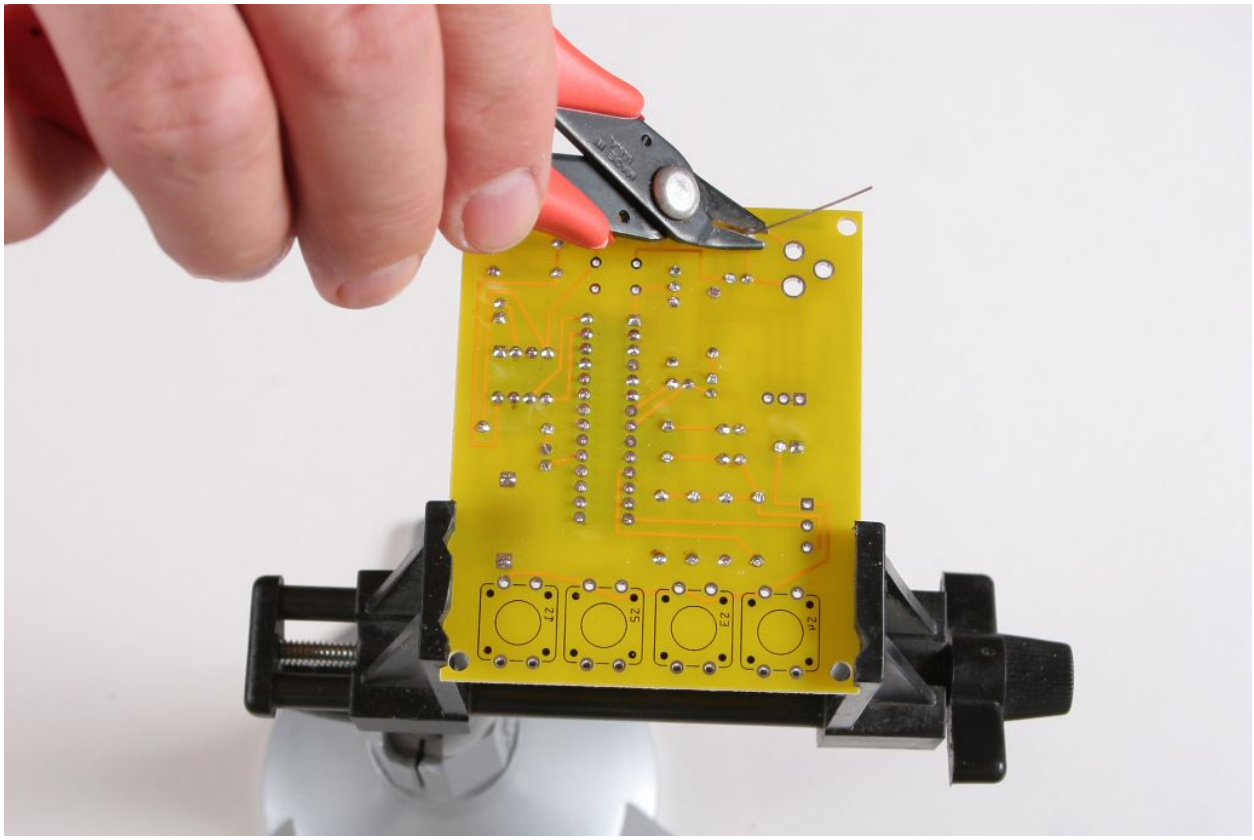


Place the 100uF electrolytic capacitors on C2. Electrolytic capacitors are polarized, make sure to insert the long wire into the round hole marked with a (+) sign.

Solder



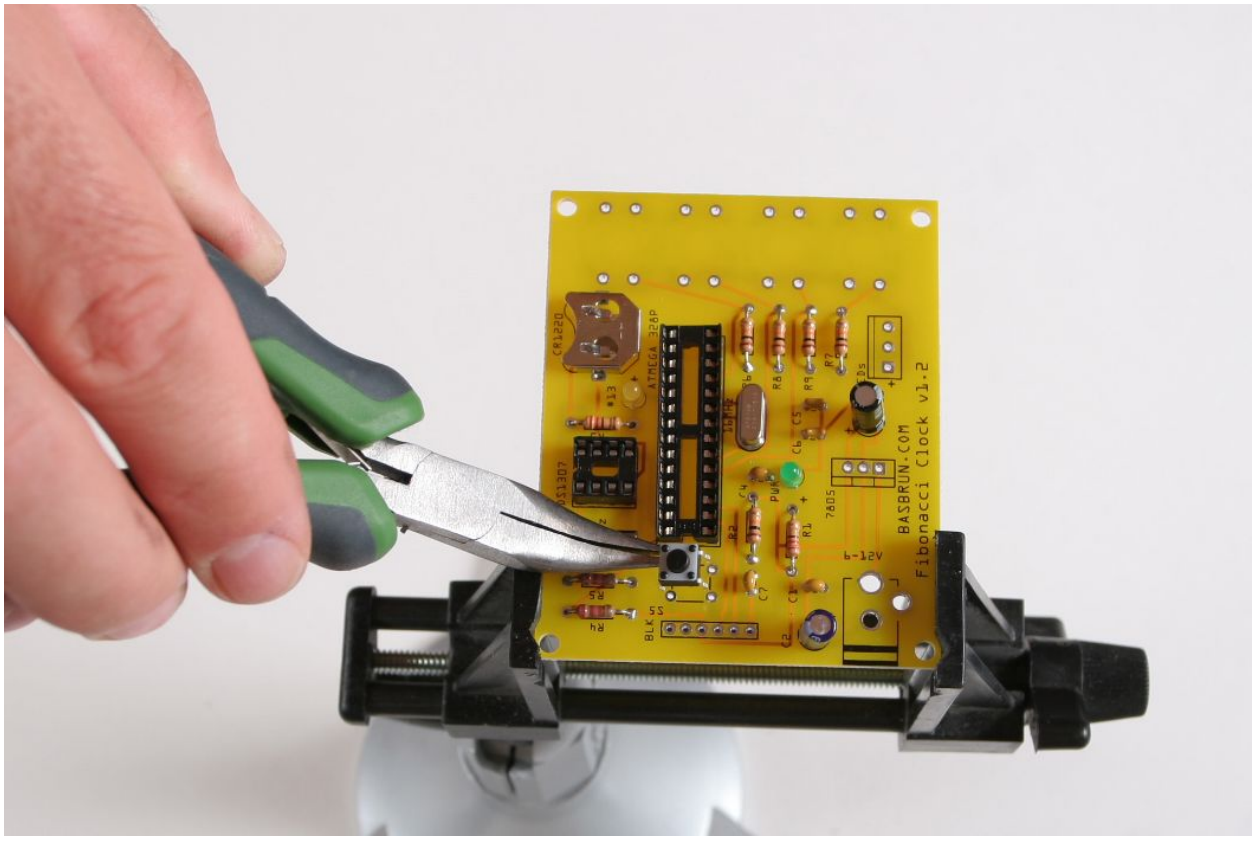
Cut the excess wires.



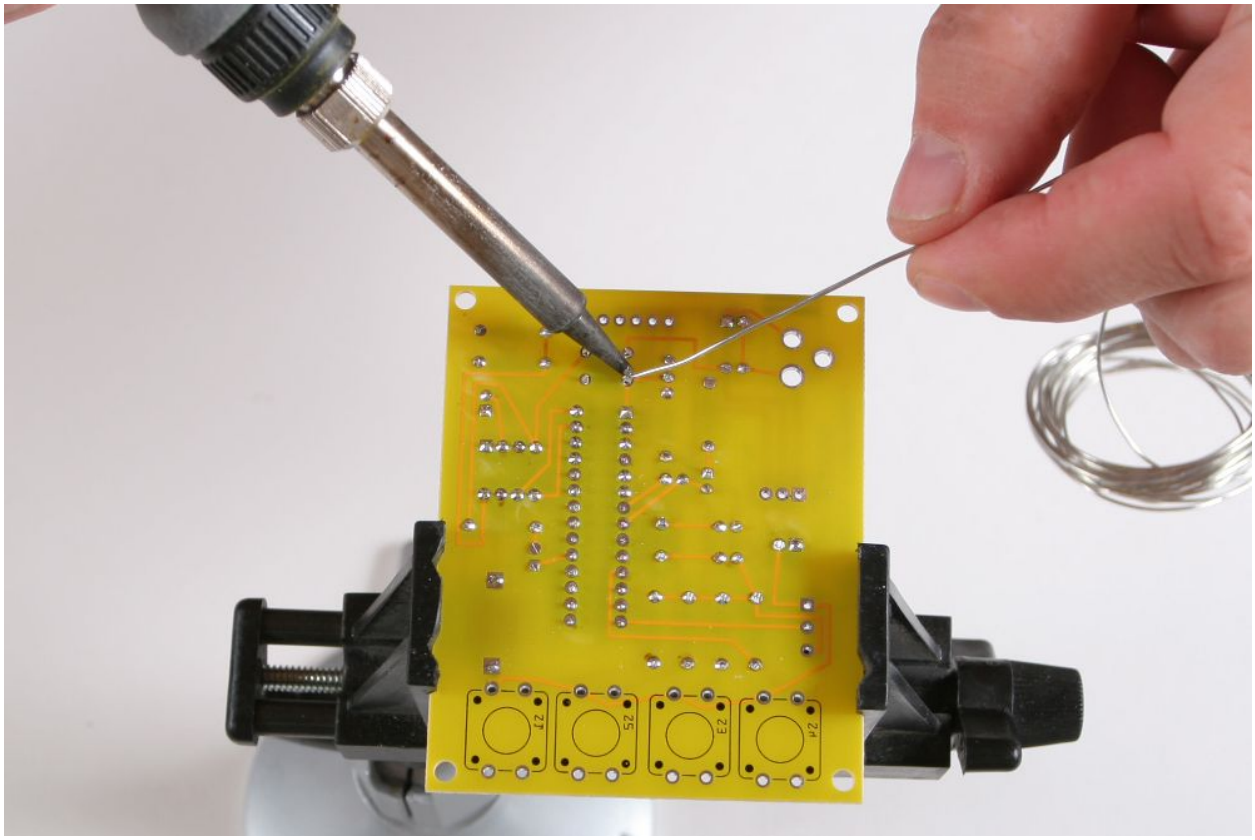
Reset Switch

Parts	Quantity	Image
SWITCH TACTILE SPST-NO 0.05A 24V	1	

Place the reset switch in its location between the Atmega328P DIP socket and the FTDI port. The pins of the switch must be facing the top and bottom sides of the board.



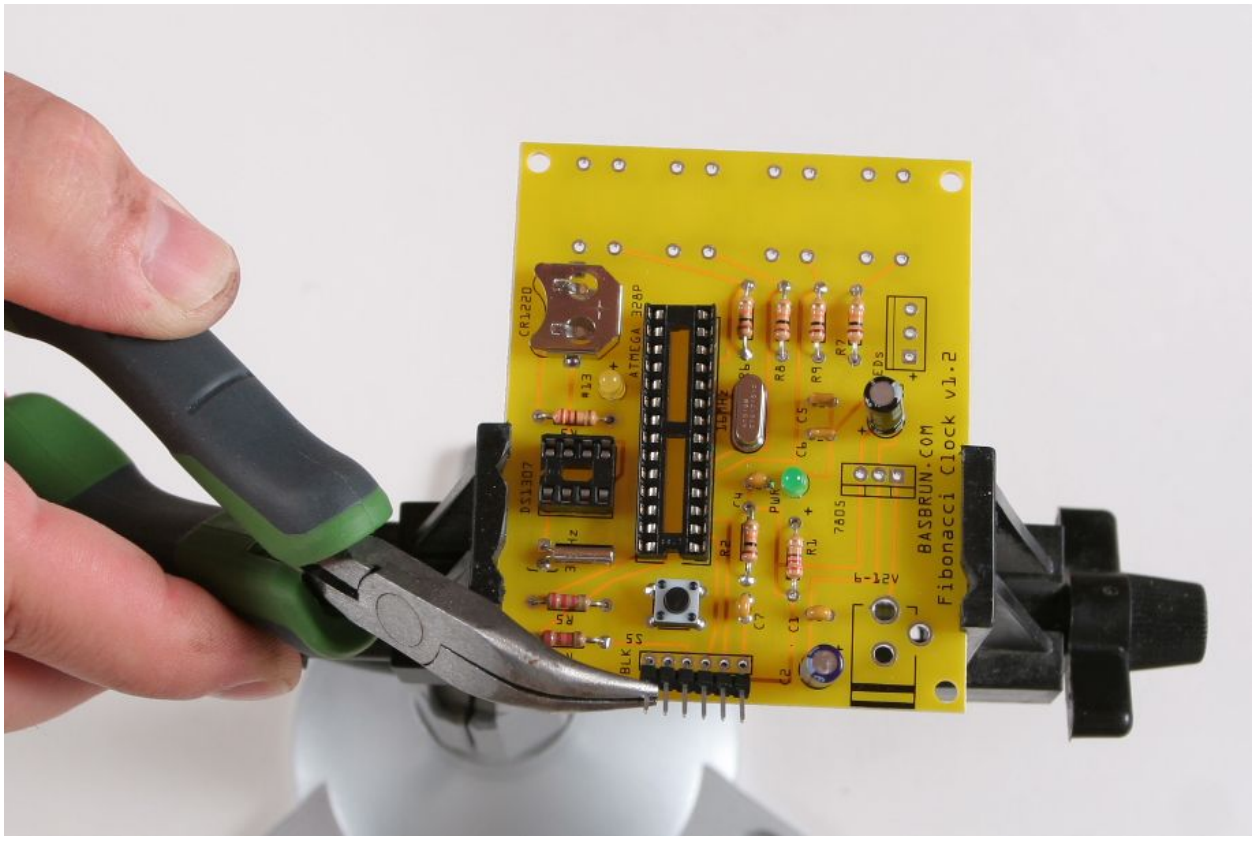
Solder



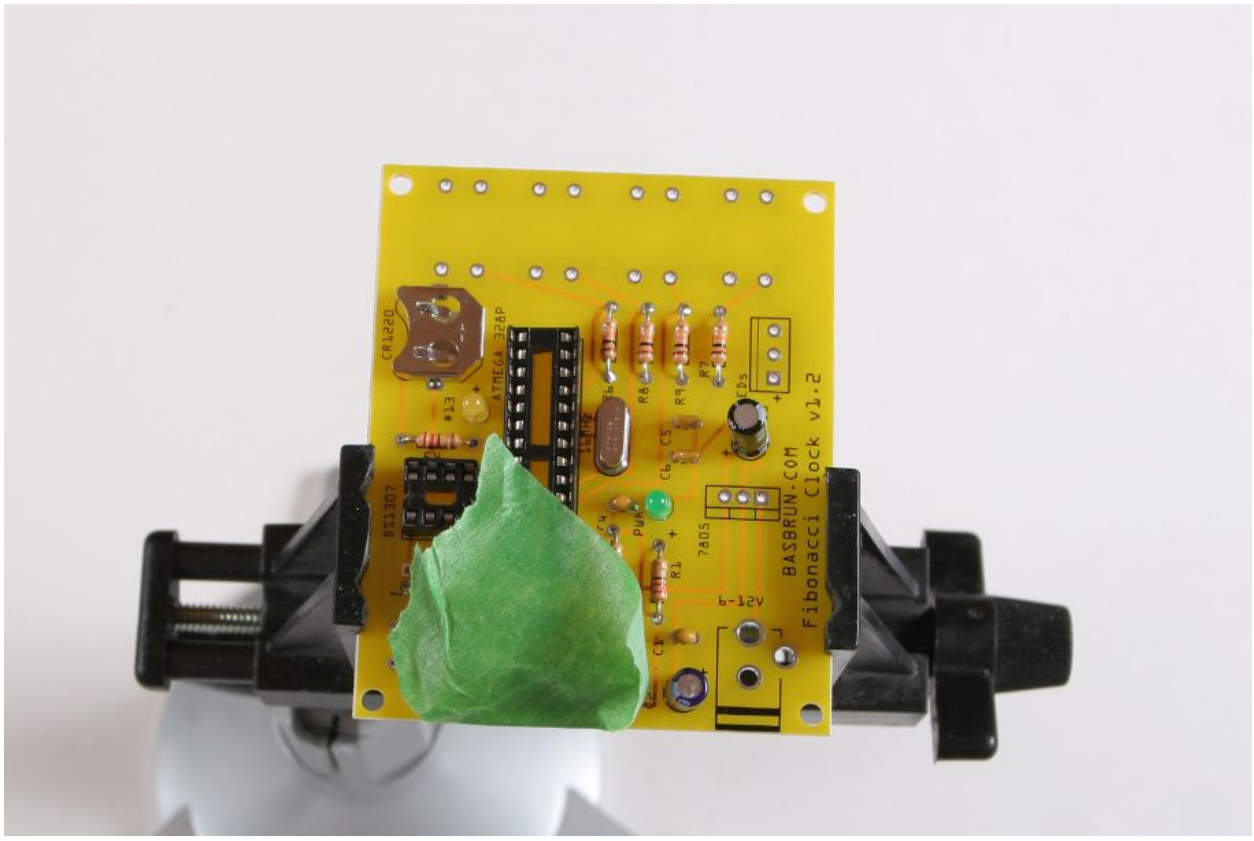
FTDI Port

Parts	Quantity	Image
CONN HEADER 6POS .100 STR TIN	1	

Place the male header with the long pins facing up.



Secure with tape.

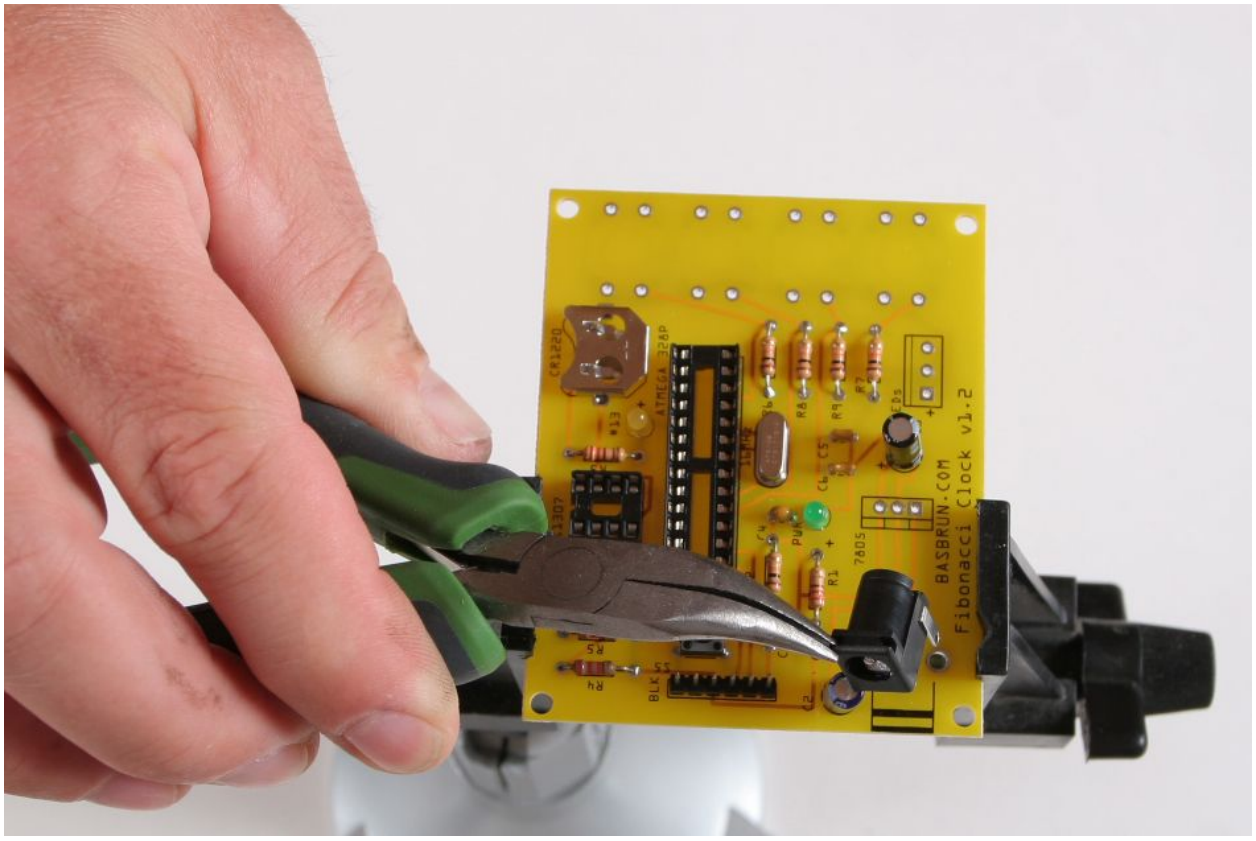


Solder the male header.
[NO IMAGE]

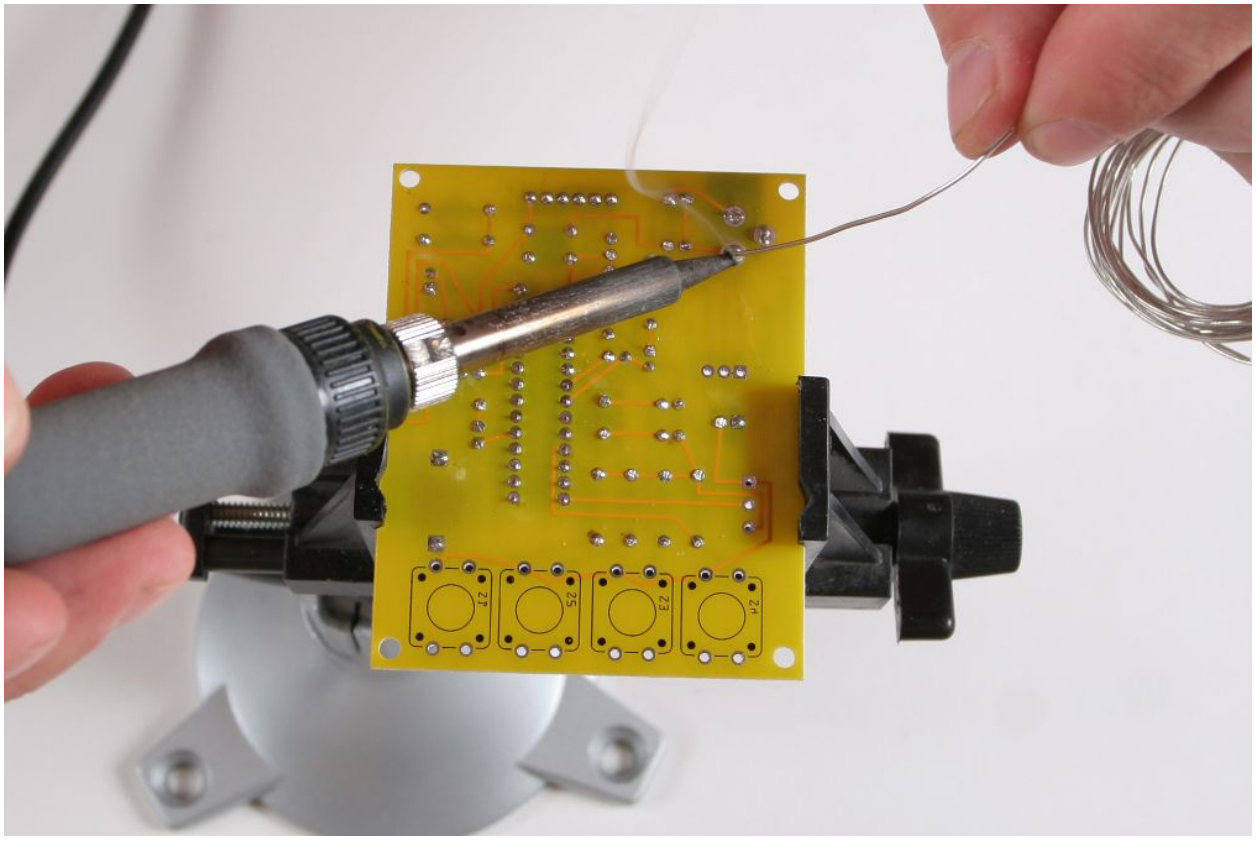
Power Connector

Parts	Quantity	Image
CONN POWER JACK 2.1MM	1	

Place the power connector in its location and secure with tape if necessary.



Solder



Voltage Regulator

Parts	Quantity	Image
HEAT SINK TO-220 .375" COMPACT	1	IC REG LDO 5V 1.5A TO220	1	

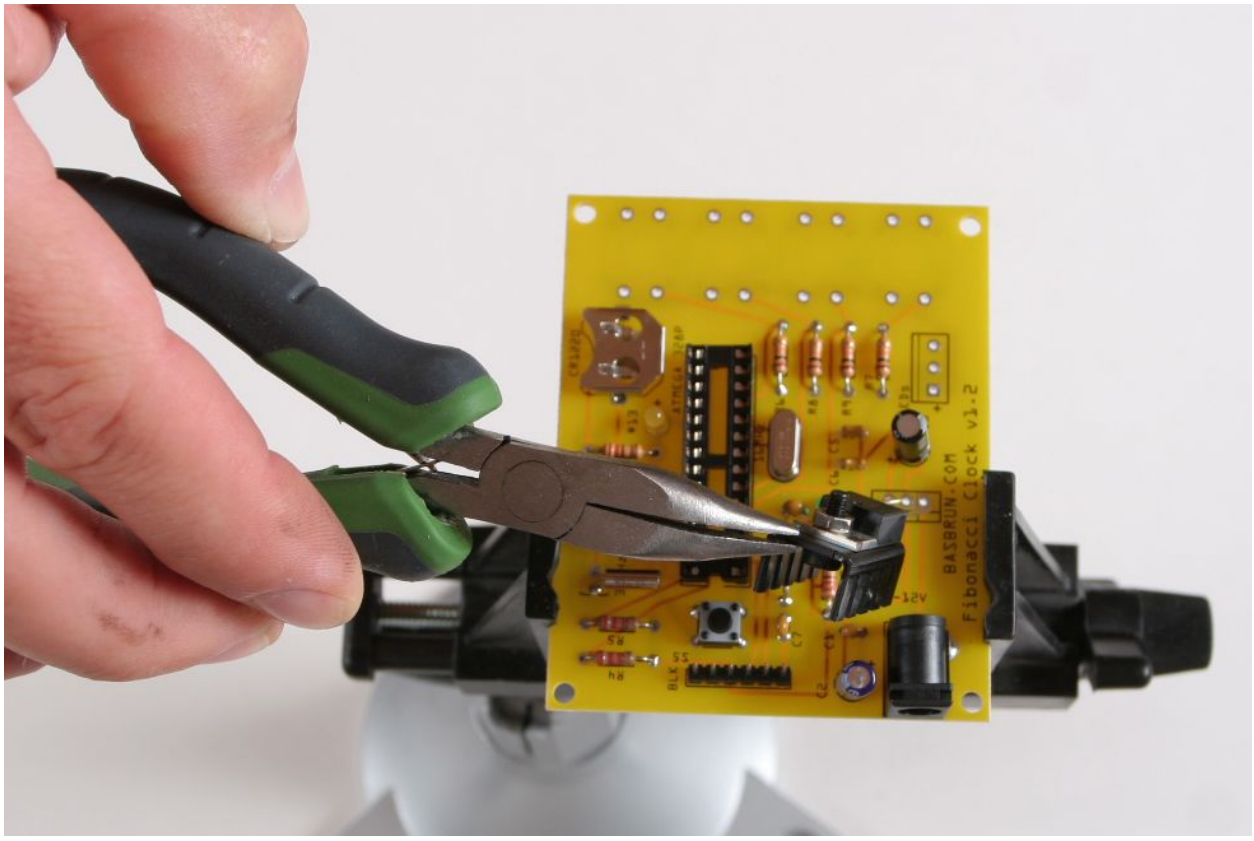
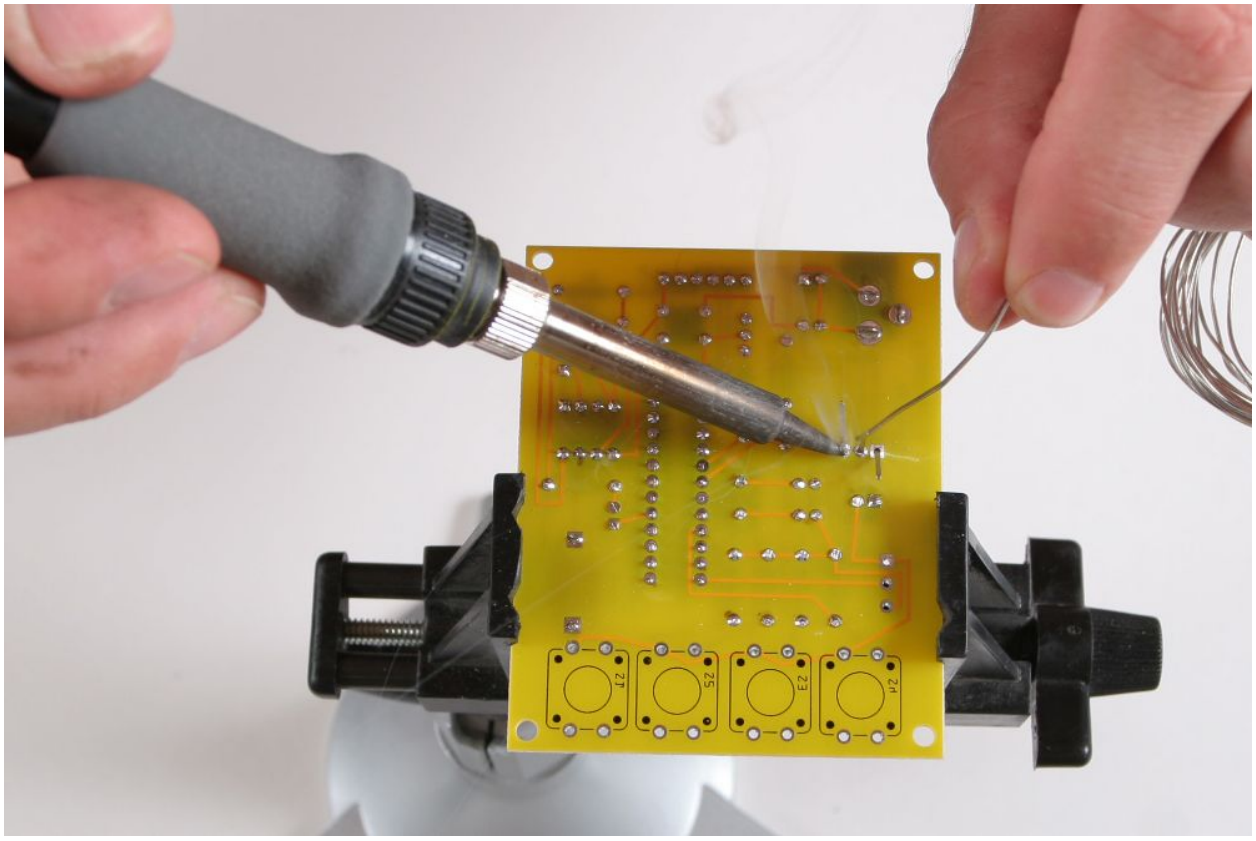
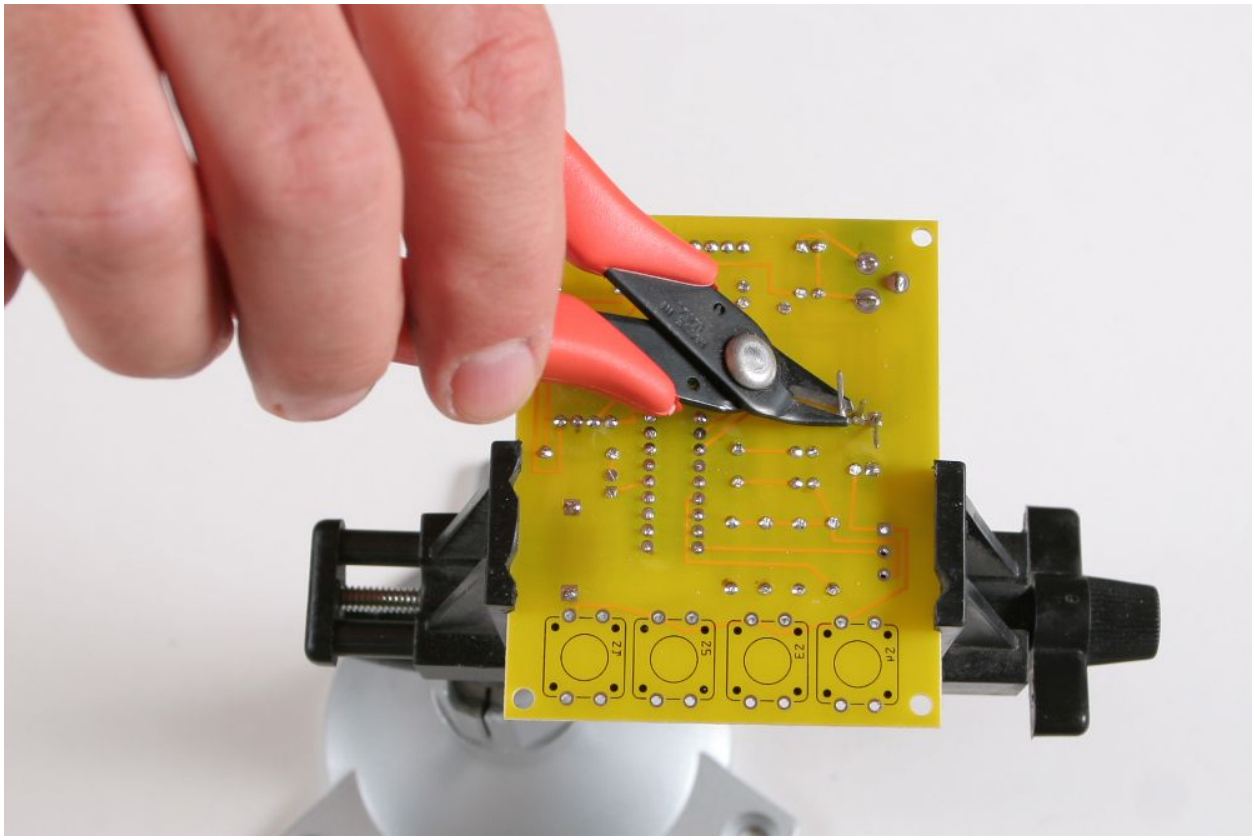
Place the voltage regulator and heat-sink assembly in the place marked 7805. The heat-sink should face the power connector.



Solder



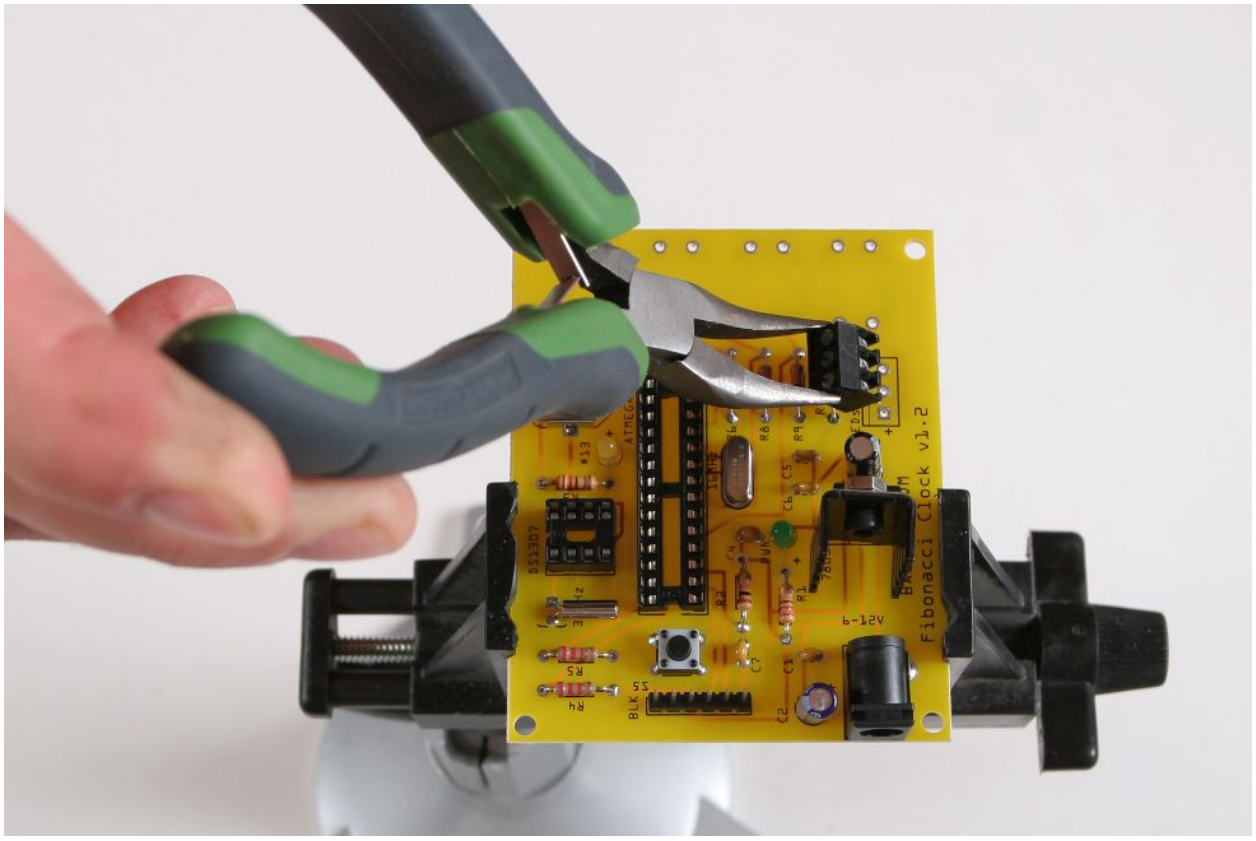
Cut the excess wires.



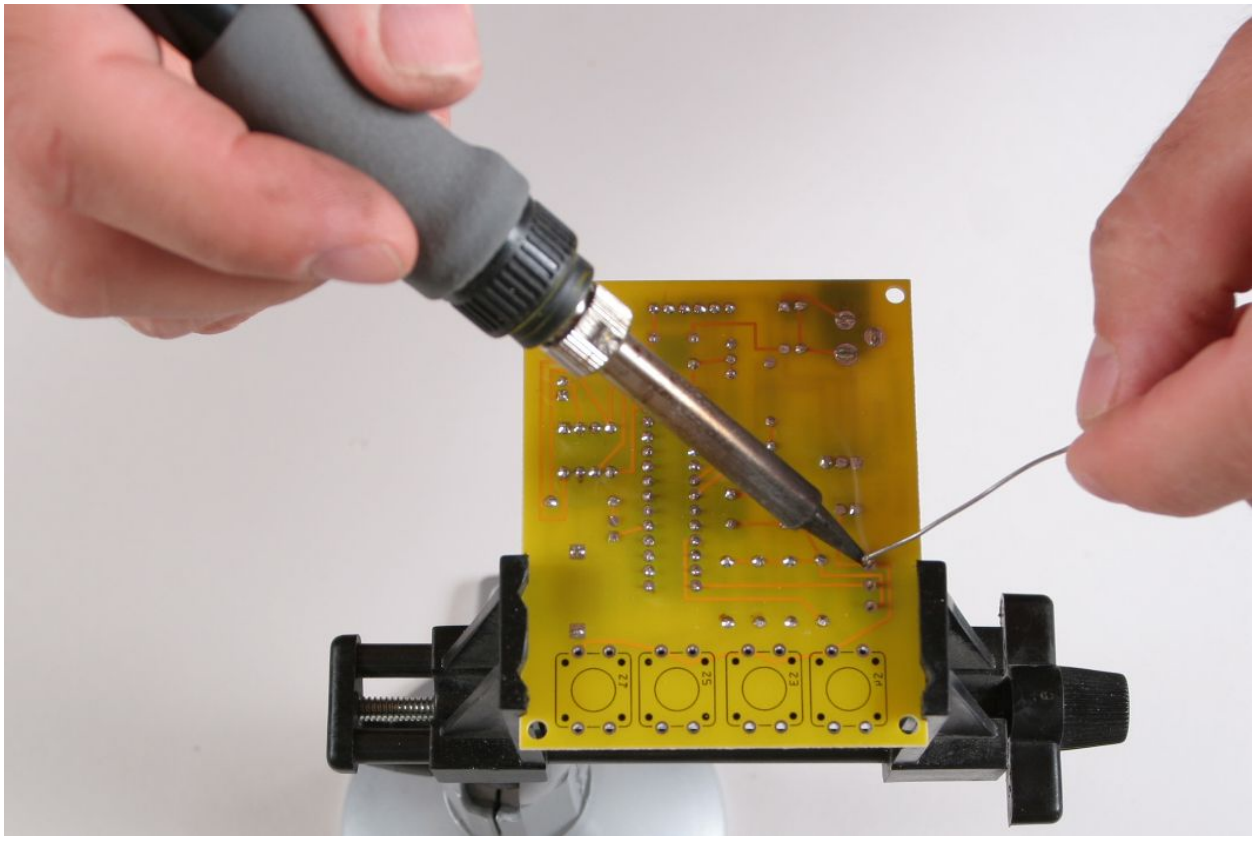
Terminal Block

Parts	Quantity	Image
TERMINAL BLOCK 3.5MM 3POS PCB	1	

Place the terminal block on the board with the beveled side facing the bottom edge of the board. Secure the part with tape if necessary.



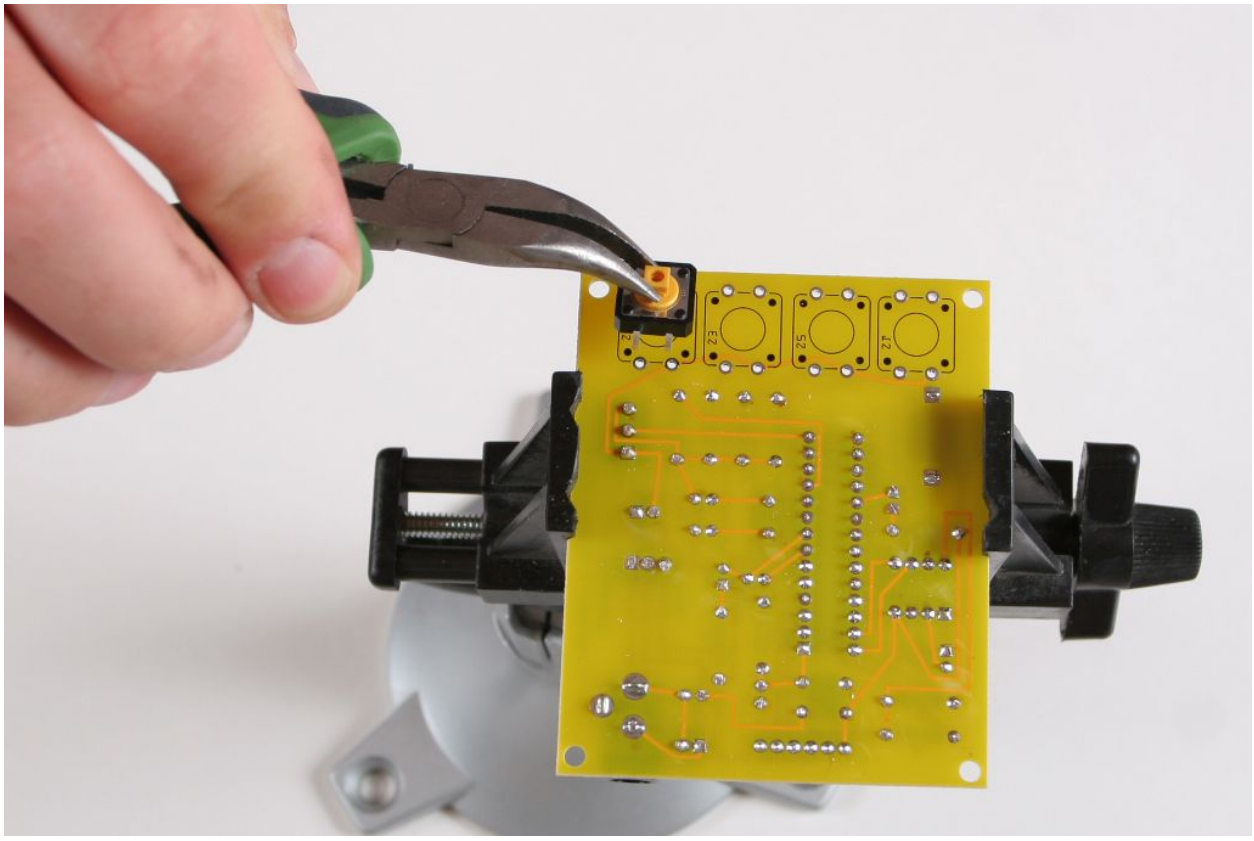
Solder

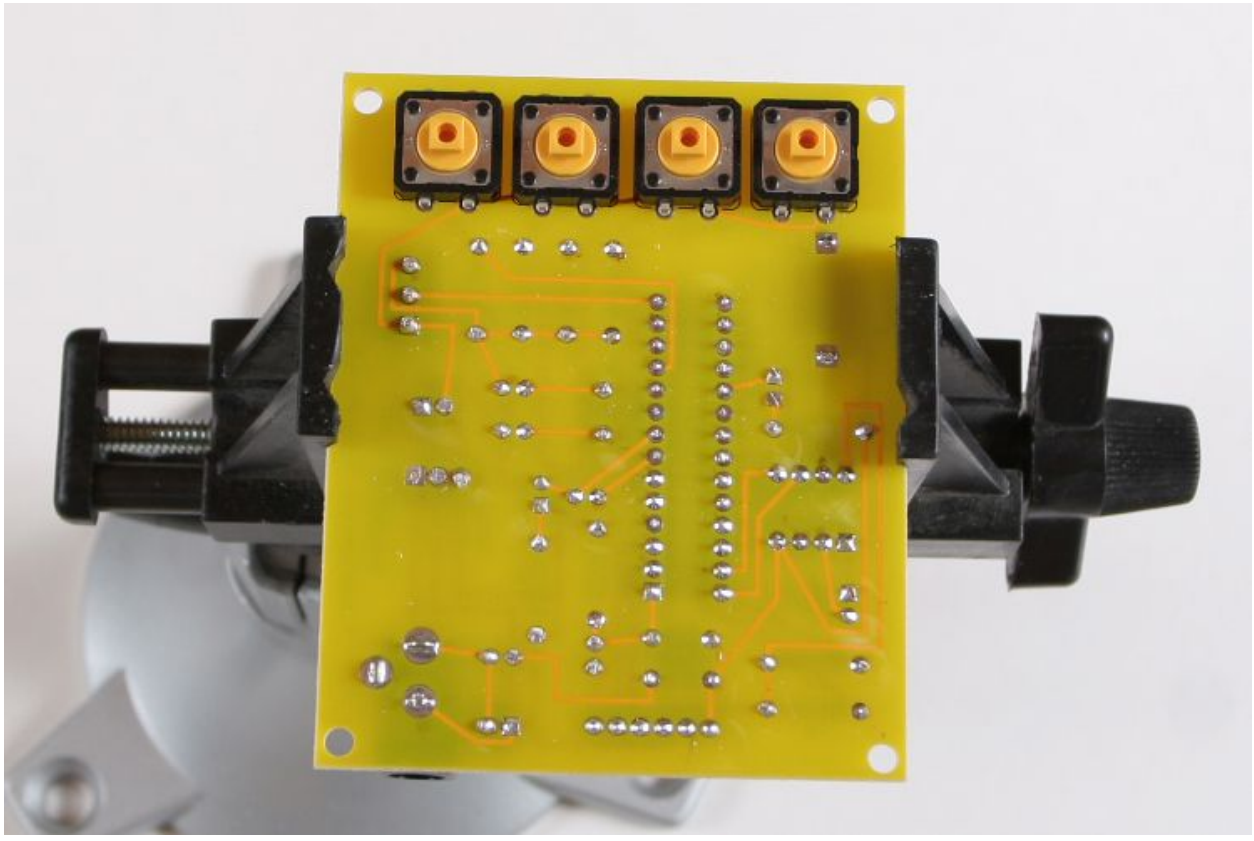


Clock Buttons

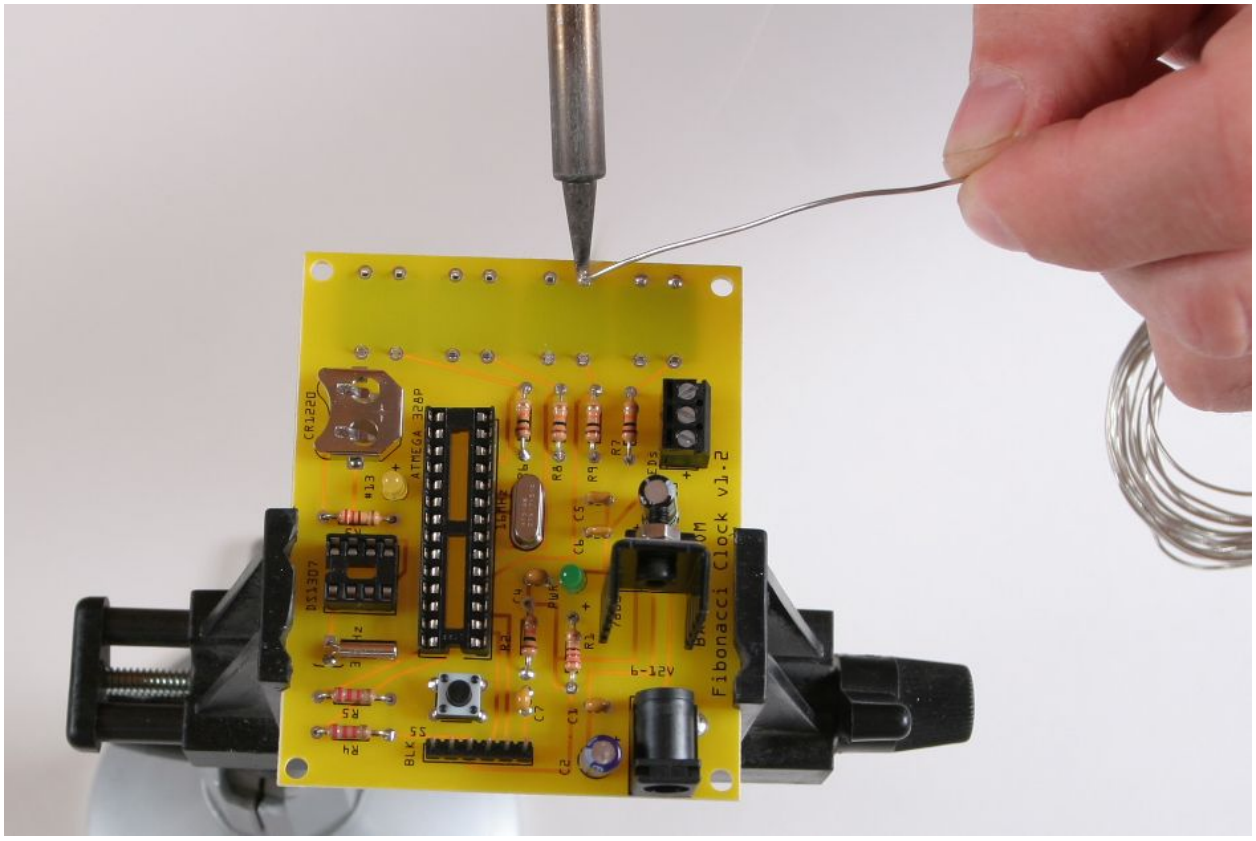
Parts	Quantity	Image
SWITCH TACTILE SPST-NO 0.05A 24V ***May be all black in your kit***	4	

Turn the board on the other side and place the four buttons in their location. They should snap in place.





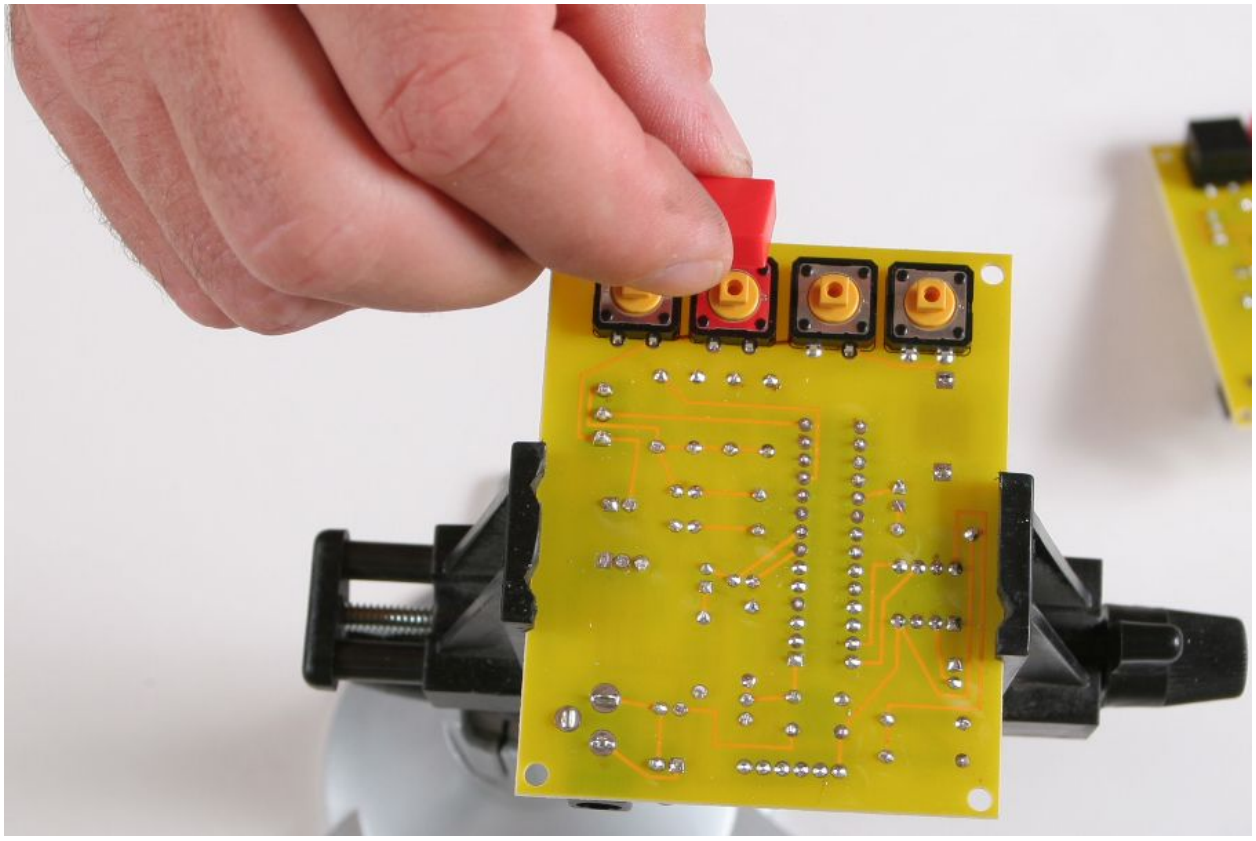
Solder

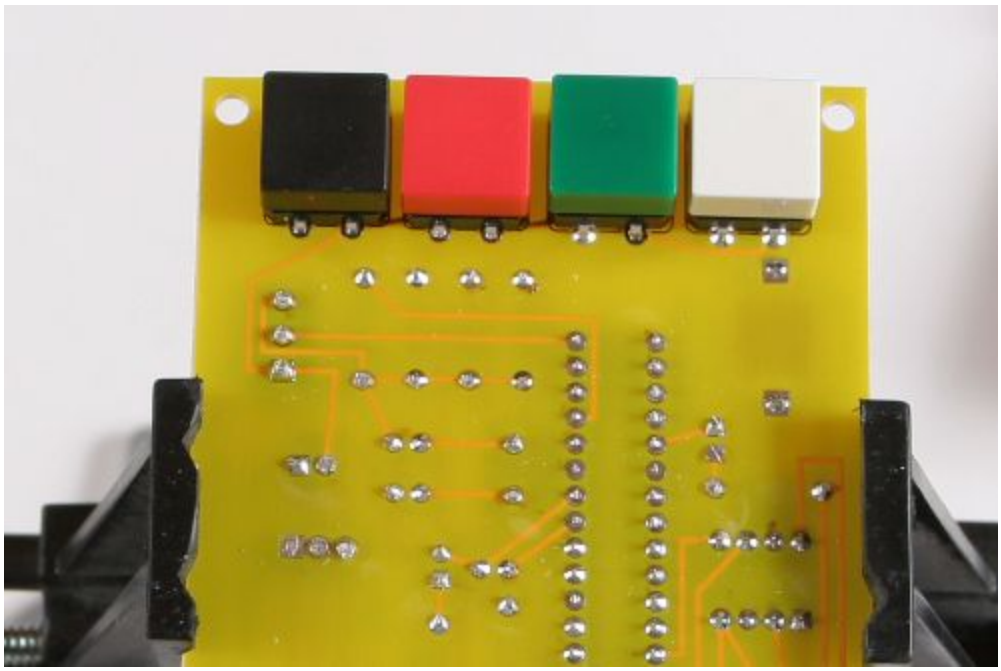


Buttons caps

Parts	Quantity	Image
CAP TACTILE SQUARE RED	1	
CAP TACTILE SQUARE WHITE	1	
CAP TACTILE SQUARE GREEN	1	
CAP TACTILE SQUARE BLACK	1	

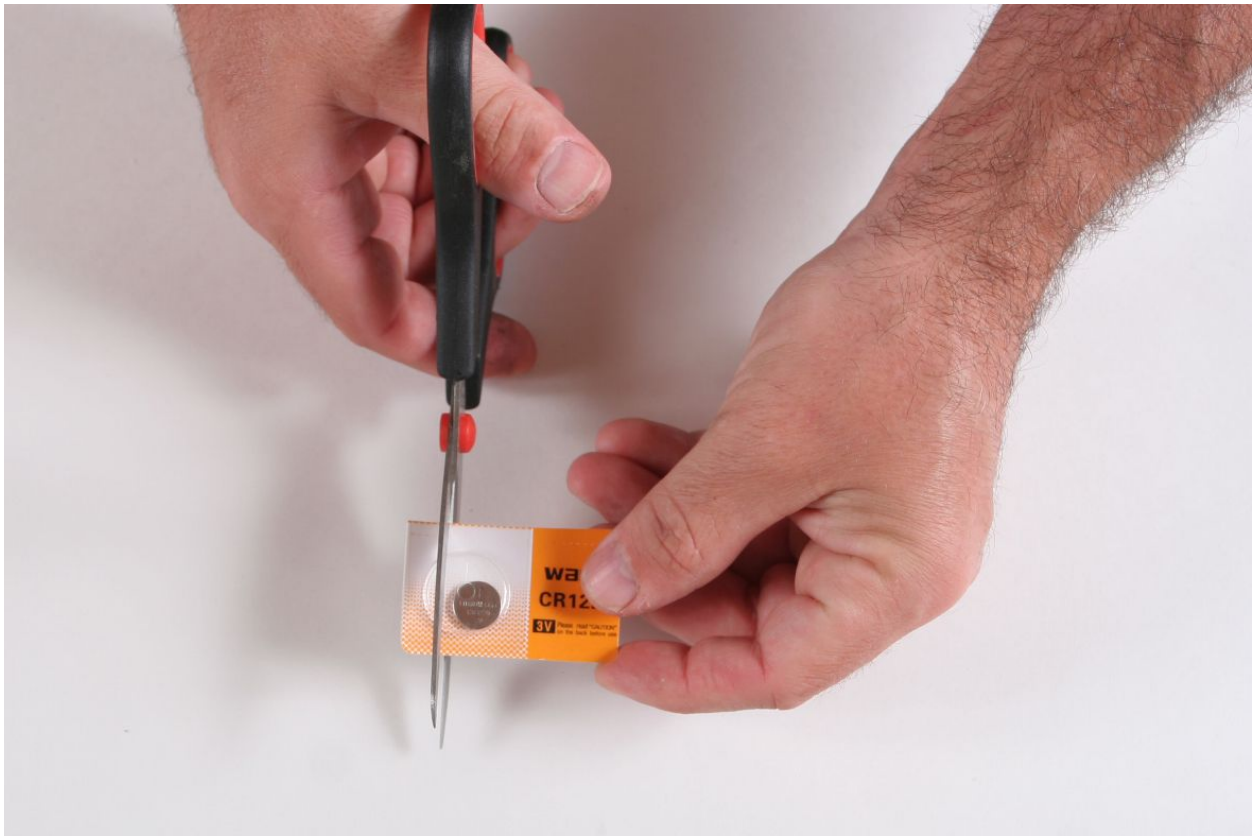
Place the button caps as displayed on the following picture. *Some kits come with button caps with a pin in the center of the socket. You may have to cut it if the button in your kit don't have a center hole.*

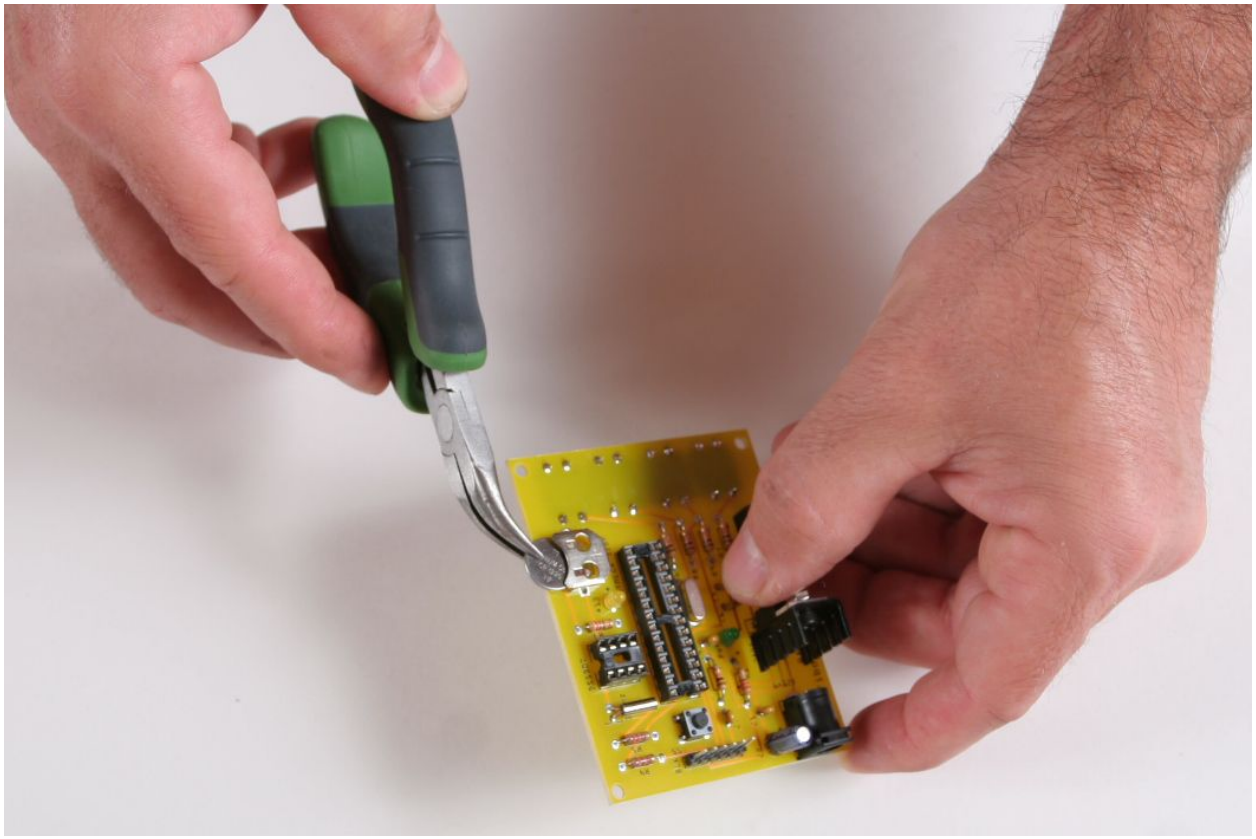


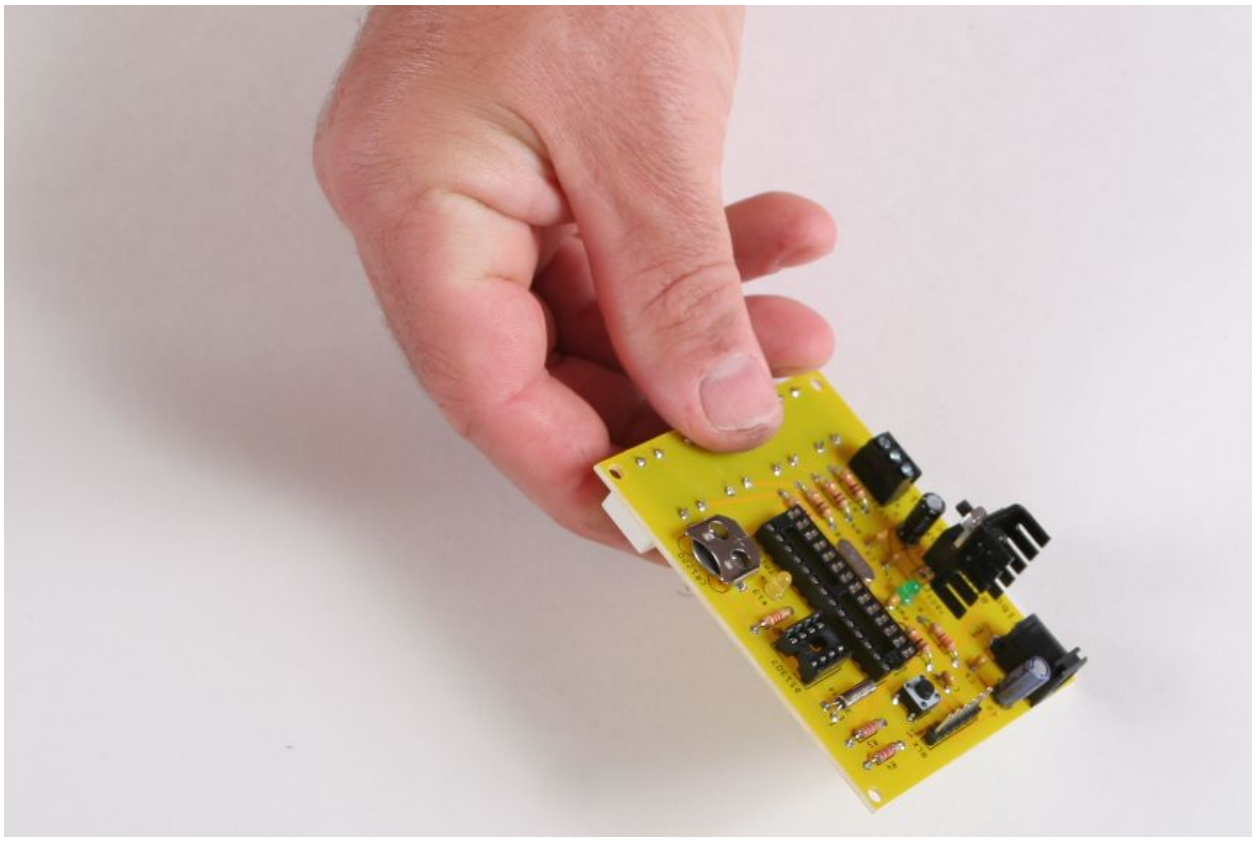


Coin Battery

Insert the coin battery in the battery holder.

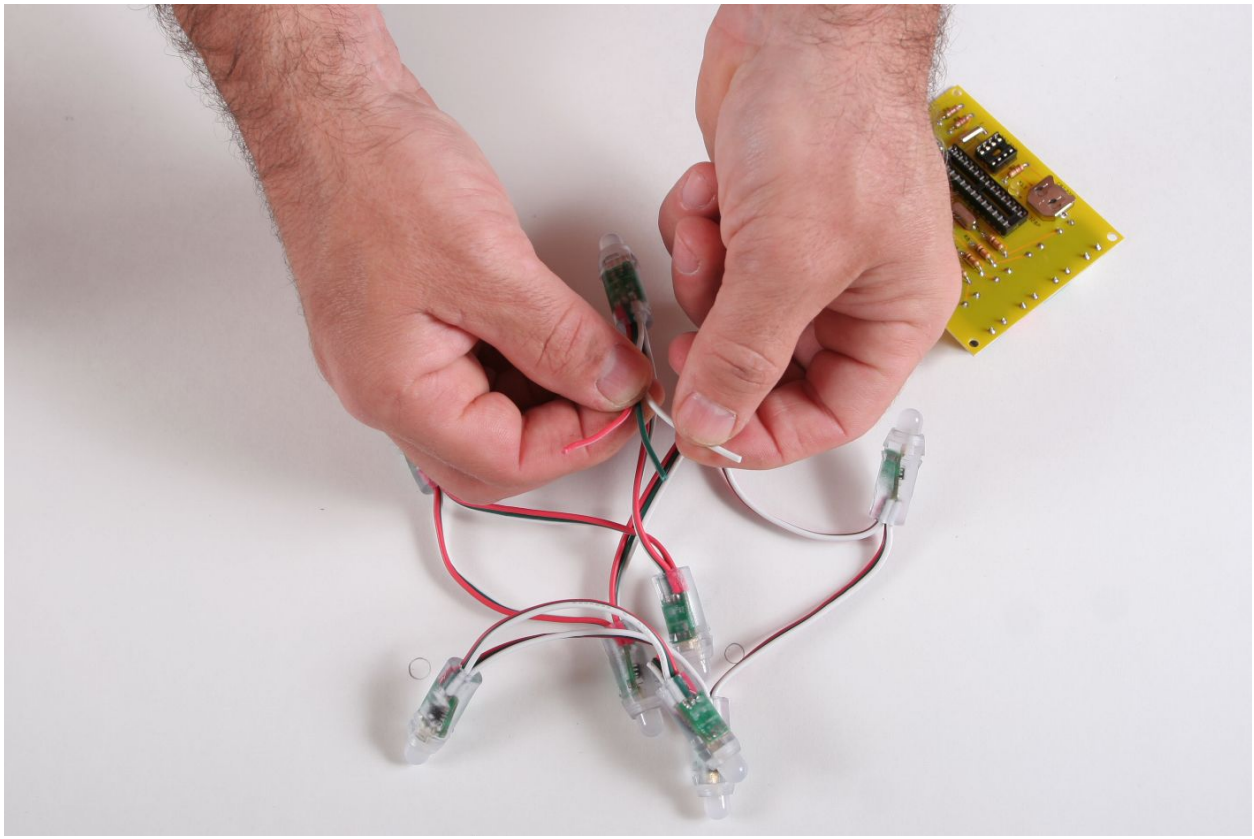






LED Pixels

Separate the three wires of the LED strip.



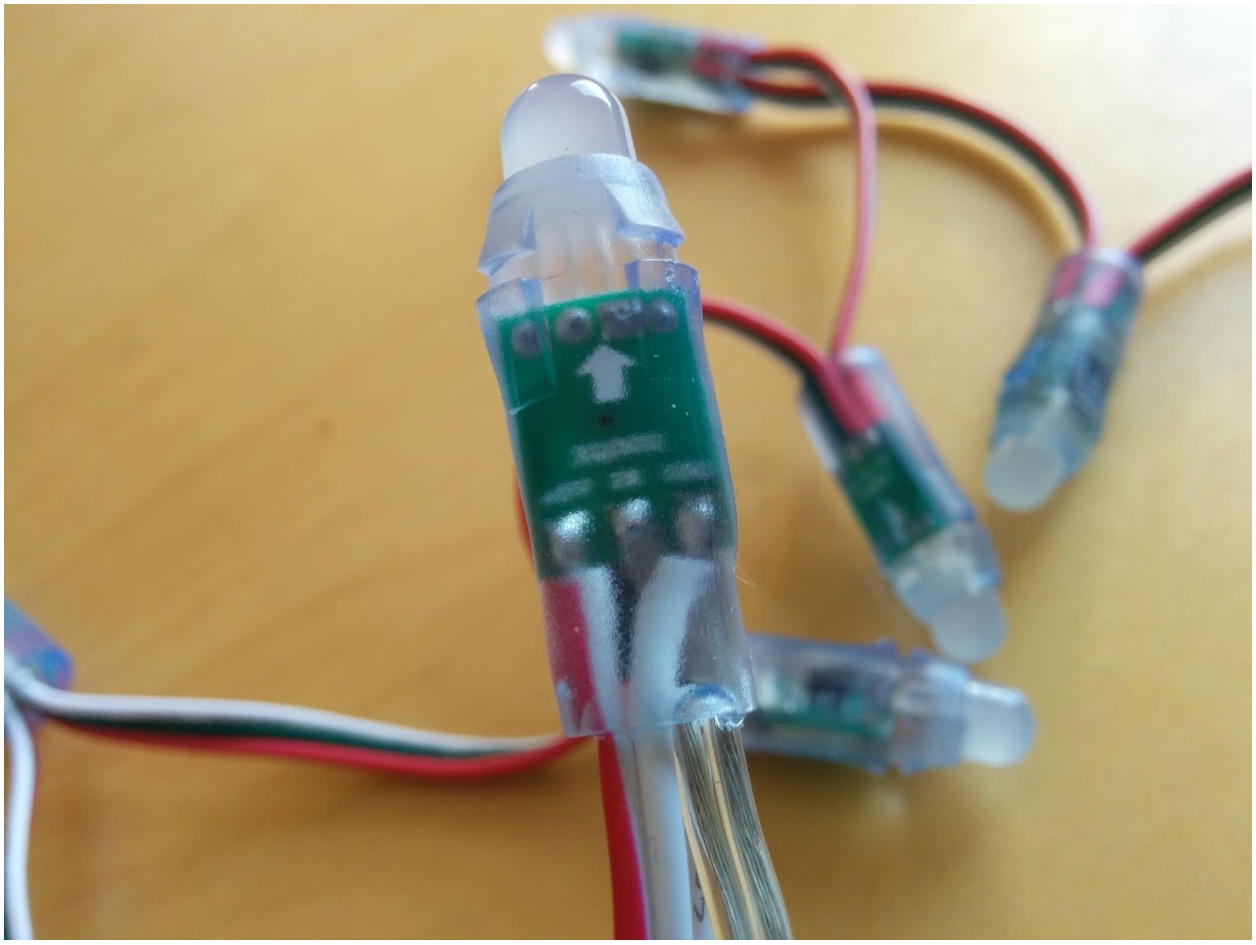
Strip the wires on approximately 5mm.

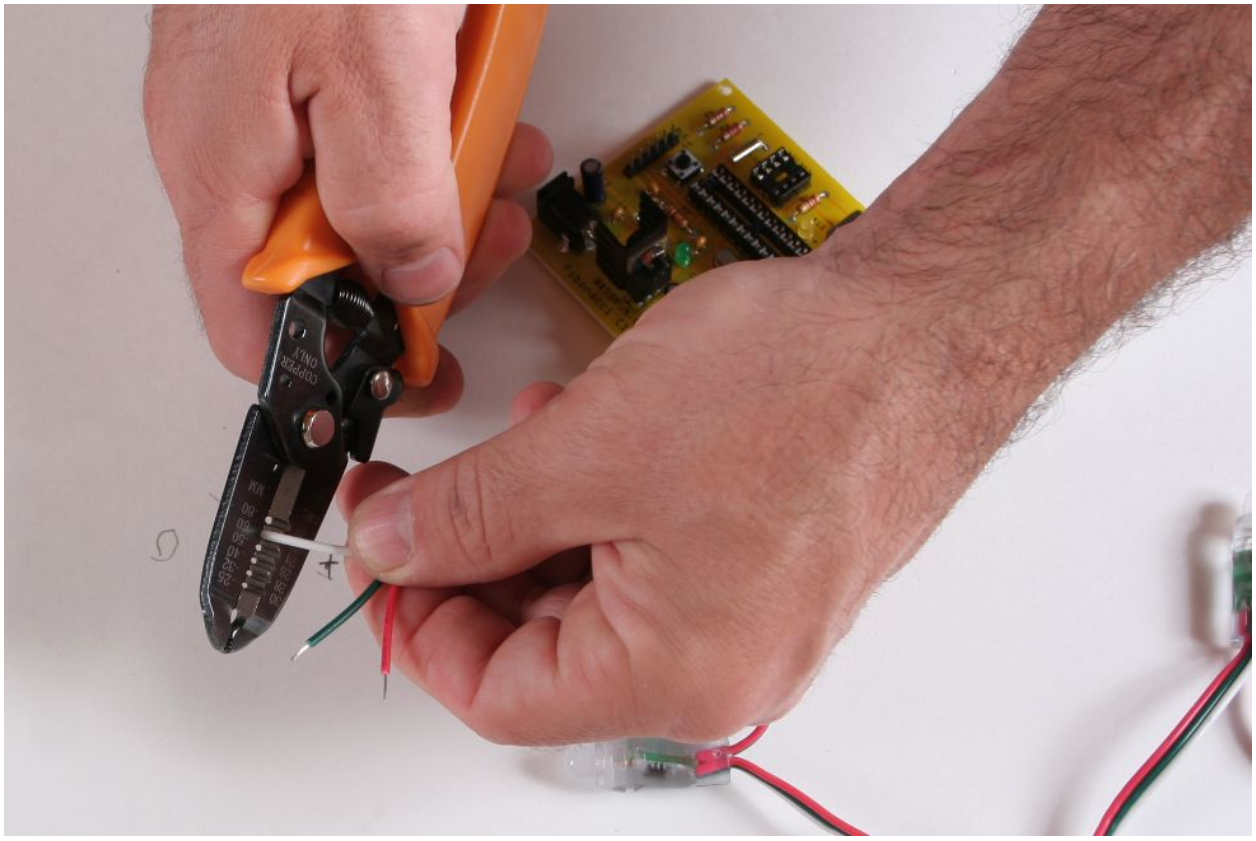
Important note **Some kits will ship with a slightly different LED strip. The green wire being replace by two transparent wires.**

One of the transparent wires replaces the green wire while the other is connected with the white wire on the ground.

You should use the transparent wire soldered to the center pin of the LED circuit board. If you are not sure what wire this is use a voltmeter to test connectivity between the transparent wires and the white wire. You should connect the one not connected to the ground (white).

An LED strip with two transparent wires. Uses the one connected to the center pin of the circuit board (IN). The other is connected to the ground with the white wire and can be ignored.





Screw the wires in the block terminal. Insert the red wire in the terminal marked with a (+) sign.

CLASSIC CRYSTAL

A low-cost crystal set that will enrich any collection.

by George Campbell

YOU CAN RELIVE THOSE EARLY days of broadcasting by building this authentic reproduction of a crystal radio from the early part of this century. This afternoon's project uses the same components, mostly hand-built, that your grandfather used to use, and costs less than $10 to build.

The heart of this receiver is an authentic crystal detector, using a natural galena crystal and a cat-whisker. It is available by mail order (see parts list for ordering information). The coil and the condenser are also handmade, using original techniques from the early '20s.

Old-Style Components. Begin by laying out the wood base according to the drawing. You may use any wood you choose, as long as it's dry and well-seasoned. Drill 3/32-inch pilot holes for the screws and 5/32-inch holes for the binding posts. Counterdrill the binding post holes ¾-inches deep with a ⅜-inch bit. Glue the slider support block to the base, then give the entire base two coats of shellac, the original finish for most of those old-time sets.

While the base dries, make the coil and condenser. The coil is wound on 4 inches of a 7-inch section of a rolling pin. Remove the handle from one end and withdraw the iron rod that passes through the rolling pin. Cut the rolling pin to length, and put the nylon bearing from the unused end of the pin in the hole in the 7-inch section.

Drill 1/16-inch holes completely through the wood, 1½ inches from each end. Use the original rod from the pin as an axle, and carefully wind a single, smooth layer of No. 25, coated copper magnet wire between the holes. The coil must be tight, with no overlaps. Pass the wire ends through the pre-drilled holes to anchor the coil, then give it two coats of shellac.

The crystal/whisker act as a rectifier diode to detect audio from the tuned LC circuit.

Next, cut the parts of the condenser as shown in the diagram. On a hard surface, stack the strips together, beginning with the Kraft paper, then waxed paper, then foil, waxed paper, foil, waxed paper, and Kraft paper.

The roll-your-own capacitor is made of metal foil and paper—just like the old days.

CLASSIC CRYSTAL

The L-shaped ends of the foil should be at opposite ends of the stack, and protrude from opposite sides. Make sure the foil is centered between the layers, then bind the edges of the condenser together up to the foil with masking tape. Roll the bundle up tightly. Cover the completed condenser with masking tape and crush the protruding foil into wire-like leads.

Make the slider from a ⅛- by ½-inch brass strip, 6 inches long. Round the corners with a file and drill a 5/32-inch pivot hole, 1 inch from one end and a 3/16-inch hole for the knob at the other. Solder a 3-inch piece of No. 12 bare copper wire to the underside of the slider to make contact with the coil.

Assembly. Mount all components on the base, using No. 5 x ½ inch brass, round-head wood screws. Place a fiber washer under the tuning slide pivot to reduce friction. Locate the tuning coil so that the holes in the nylon bushings line up with the top holes in the brass L-brackets. Use a No. 8 wood screw here. Attach the rubber feet to the bottom of the base.

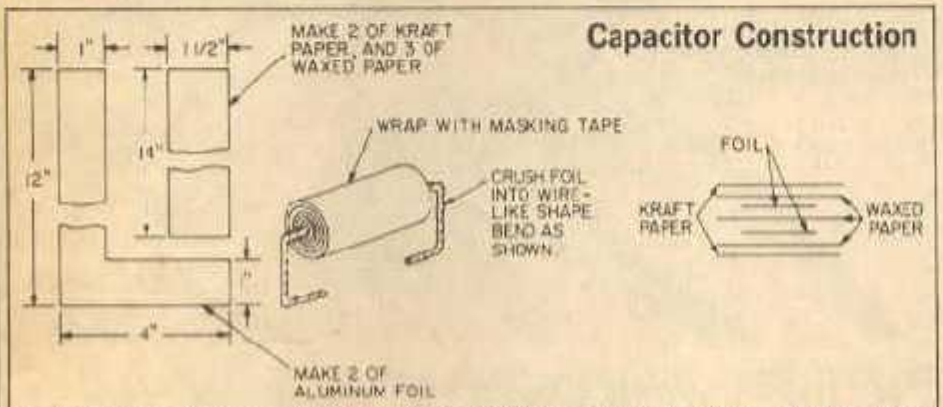
Wire the receiver according to the drawing, using No. 20 copper wire. Remove the insulation and shellac from the top of the tuning coil with fine sandpaper, and bend the tuning slide slightly to provide good contact with the bare wire of the coil.

To use your crystal set, connect the antenna binding post to a good anteanna (one side of a TV lead-in works well). The ground post must be connected to a good ground, such as a cold water pipe. The headphones used with this set must be the high impedance type. Normal stereo headsets will not work with this primitive receiver. If you wish, you can attach the center conductor of a shielded cable to binding post J3, the shield to J4, and plug the other end into an amplifier to provide loudspeaker reception and easier listening.

Locate a sensitive spot on the galena crystal by slowly dragging the cat-whisker spring over its surface with the tuning slide centered on the coil. Once a sensitive spot is found, you should hear a local station clearly. Tuning this receiver takes time and patience, so don't give up.

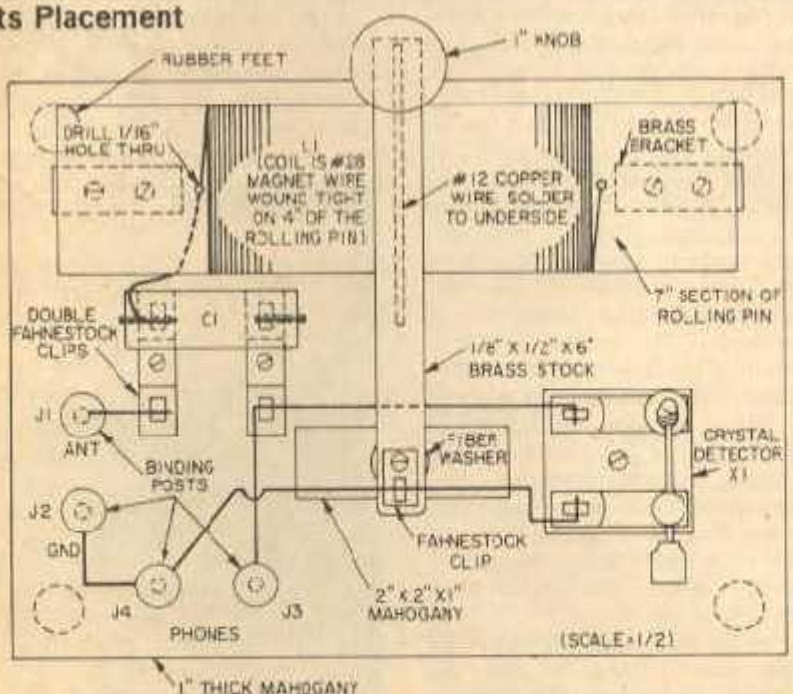
Don't be surprised if you hear more than one station at once. Crystal sets are not very selective. However, careful adjustment of the tuning slide should separate stations reasonably well. And who knows? One day you may even hear a voice from the past. ■

Capacitor Construction

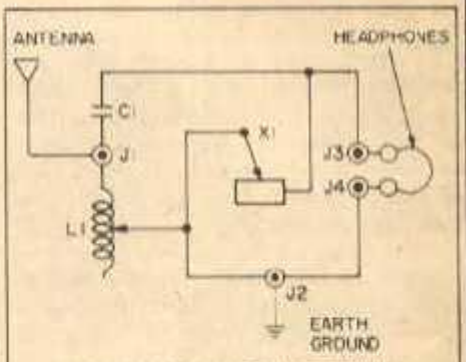


To build the capacitor (C1) cut strips of aluminum foil, kraft paper, and wax paper according to the patterns above. Then interleave the strips as shown above, with the L-shaped ends of foil at opposite ends of the bundle, facing in opposite directions. Bind the edges with masking tape and roll the bundle tightly. Test it with a VOM: if the meter moves and then goes back to infinite resistance then C1 is OK. If not, rebuild C1.

Parts Placement



This parts' location diagram shows the relative positions of all the parts. It is drawn to half-scale, so multiply any distance by two to get the full-scale measurements. The wire connections are the bold lines. Wind the coil for four inches along the rolling pin. The non-functional coils on each side of the wiper in the photograph are for decoration.



PARTS LIST FOR CRYSTAL SET REPLICA

Misc.—6- x 8-inch wooden base, 2- x 2- x 1-inch wood slider support block, aluminum foil, wax paper, kraft paper, 150 feet No. 26 coated, copper magnet wire, 3 feet No. 20 copper wire, 3 inches No. 12 copper wire, wooden rolling pin, 2 No. 18 double Fahnestock clips, 1 No. 18 single Fahnestock clip, ⅛- x ½- x 6-inch brass strip, fiber washer, rubber feet, wooden knob, two 1½-inch brass "L"-brackets, assorted brass round-head wood screws.

Construction and Operation of a Simple Homemade Radio Receiving Outfit

The 1922 Bureau of Standards publication, *Construction and Operation of a Simple Homemade Radio Receiving Outfit* [1], is perhaps the best-known of a series of publications on radio intended for the general public at a time when the embryonic radio industry in the U.S. was undergoing exponential growth.

While there were a number of earlier experiments with radio broadcasts to the general public, most historians consider the late fall of 1920 to be the beginning of radio broadcasting for entertainment purposes. Pittsburgh, PA, station KDKA, owned by Westinghouse, received its license from the Department of Commerce just in time to broadcast the Harding-Cox presidential election returns. In today's world where instant global communications are commonplace, it is difficult to appreciate the excitement that this event generated.

News of the new development spread rapidly, and interest in radio soared. By the end of 1921, new broadcasting stations were springing up all over the country. Radios were selling faster than companies could manufacture them. The demand for information on this new technology was almost insatiable. The Radio Section of the Bureau of Standards provided measurement know-how to the burgeoning radio industry as well as general information on the new technology to the public. Letters to the Bureau seeking information on radio technology began as a trickle, and then soon became a flood. Answering them became a burden.

Circular 120, published in April 1922, began: "Frequent inquiries are received at the Bureau of Standards for information regarding the construction of a simple receiving set which any person can construct in the home from materials which can be easily secured. This publication has been prepared to meet these inquiries." The circular also noted that the Bureau was cooperating with the Bureau of Markets and Crop Estimates of the Department of Agriculture. In the early days of radio, broadcasts to farmers of crop price reports were an important public service.

In 1921 factory-made radios were very expensive. Many of them cost more than $2000 in today's dollars, and less affluent families could not afford to have one. When the Bureau published this circular (which sold for only five cents) on how to build a simple crystal radio at home, it was an instant success. Thousands of orders

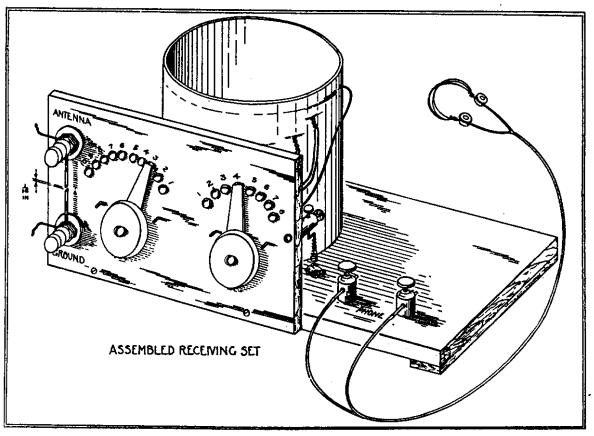

Fig 1. The crystal radio described in Circular 120.

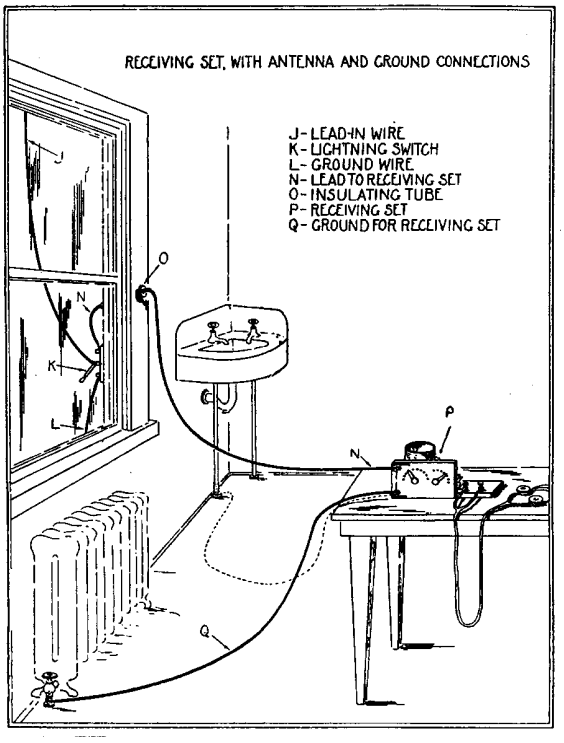

Fig. 2. Diagram showing the antenna and ground connections to the radio.

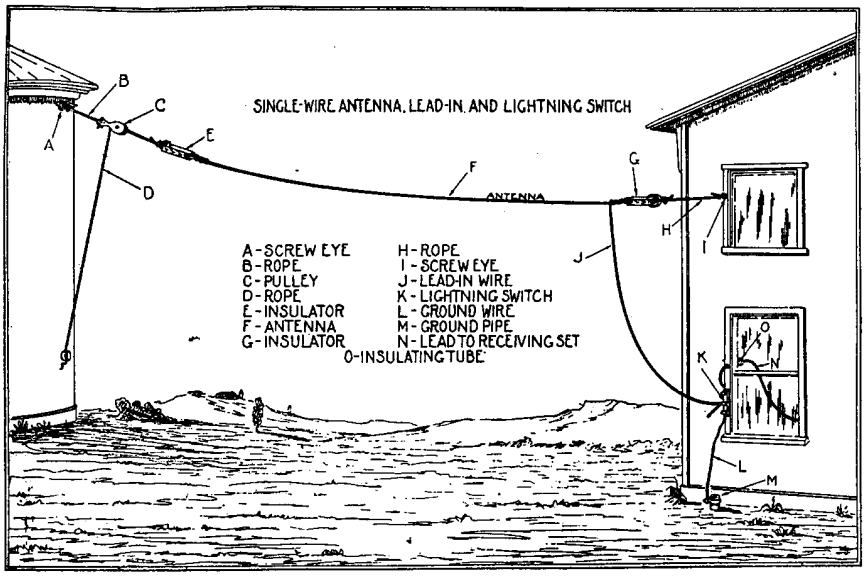

Fig. 3. Details of the outdoor antenna recommended for use with the crystal radio.

flowed in from every state. The circular showed how almost any family having a family member handy with simple tools could make a radio. The circular states "Satisfactory results have been obtained from sets constructed according to these instructions by persons having no previous experience with radio." The authors stated that the cost of the materials for the radio and associated headphones and antenna system should not exceed $10.

Newspapers around the country urged readers interested in radio to order a copy, and in many cases they reprinted the entire article. Even today, antique radio collectors searching attics and basements often come across dusty home-built crystal radio sets that were obviously constructed using the Bureau's plans. No doubt the remarkably rapid growth of the radio industry in the U.S. during the 1920s (analogous to the growth in Internet-related businesses today) was aided considerably by information provided to the public by the Bureau, such as this circular and the other items noted in the bibliography [2-6].

Circular 120 proved such a success that the Bureau published a number of other circulars on radio technology intended for the general public, as noted in the bibliography. All were popular. In some cases, commercial radio manufacturers copied the circuits proposed by the Bureau. During the same era, other radio publications of the Bureau captured public attention as well, though perhaps in smaller quantities than Circular 120. *Radio Instruments and Measurements* [7], Circular 74, published first in 1918 with a second edition published in 1924, became a best seller in the post-WW I era. Its principal authors were most likely J. H. Dellinger, J. M. Miller, F. W. Grover, and G.C. Southworth. The authors of Circular 120 are not stated, but some of those same individuals likely contributed to it. J. Howard Dellinger's story is particularly interesting. He came to the Bureau in 1907 as a laboratory assistant at $900 per year, and retired as Chief of the Central Radio Propagation Laboratory in 1948. He headed the Radio Section for much of its existence. Appendix D of Reference [9] is a biography of Dellinger.

The Principles Underlying Radio Communication [8], Signal Corps Radio Communication Pamphlet No. 40, published in 1919 and issued in a revised edition in 1922, is another interesting example of a popular radio book. Written by the Bureau of Standards for training Army Signal Corps officers, it was an expanded and updated version of Circular 74, noted above, but was also widely used by college students and others studying radio. In spite of the "pamphlet" designation, it was actually a 600-page book. Thomas Edison said ". . . This is the greatest book on this subject that I have ever read, and I want to congratulate you and your Bureau on its production."

While the general public was interested in radio information for the lay person, the fledgling radio industry needed in-depth technical assistance from the Bureau, which it got. The Bureau helped radio manufacturers make better measurements for quantities such as resistance, capacitance, voltage, and frequency. Results of Bureau research on antennas and radio wave propagation, direction finders, vacuum tube characteristics, and testing were eagerly utilized by major

companies such as General Electric, Westinghouse, Western Electric, and RCA, as well as by a myriad of small radio companies no longer in existence. At the same time that the Bureau was providing information to people constructing radios on their kitchen tables, Radio Section staff members were presenting technical papers on radio at conferences and in journals such as the *Proceedings of the Institute of Radio Engineers.* A good example of the latter is the classic work by John Miller, who discovered and explained "the Miller effect"—a feedback effect in triode vacuum tubes that limited their ability to amplify at radio frequencies [9].

Circular 120 described in detail not only the crystal radio itself but also how to construct an antenna and ground system. To minimize the cost, the circular suggested winding the tuning coil on a discarded cylindrical oatmeal box. For years afterwards, home experimenters used oatmeal boxes as coil forms for homemade radios. The crystal radio did not require batteries, but it did require the user to purchase a commercially made set of headphones (or telephone receivers as they were called in those days), since that accessory was not suitable for home construction.

One can just imagine the thrill of a farm family that had never heard a radio broadcast before trying the new set for the first time, and one of the family members crying out, "Come listen! I am hearing something!" The electronics revolution was underway and the Bureau played a significant part in accelerating the new technology.

Prepared by Brian Belanger.

QRP Special!

On the Cover: Dave Clausen, W2VV, operates NYC Resistor club station N2YCR at the group's makerspace in Brooklyn, New York.
Details on page 92.

Escape with the TM-281A

On or off the road, Kenwood's TM-281A is a mobile radio you can always count on.

As tough as nails, this MIL-STD-compliant transceiver delivers powerful performance, excellent audio clarity, and a host of advanced features. It offers superb operating ease day or night thanks to the large backlit LCD and illuminated keys. So the next time you take off, take the TM-281A.

Cushcraft

R9

80-6 Meters!

No Radials!

Cushcraft's world famous R8 now has a big brother!

Big Brother R9 now includes 75/80 Meters for local ragchewing and worldwide low band DX *without radials*!

It's omni-directional low angle radiation gives you exciting and easy DX on all 9 bands: 75/80, 40, 30, 20, 17, 15, 12, 10 and 6 Meters with low SWR. QSY instantly -- no antenna tuner needed**.**

Use full *1500 Watts* SSB/CW when the going gets tough to break through pileups and poor band conditions.

The R9 is super easy to assemble, installs just about anywhere, and its low profile blends inconspicuously into the background in urban and country settings alike.

Compact Footprint: Installs in an area about the size of a child's sandbox -- no ground radials to bury with all RF-energized surfaces safely out of reach.

Rugged Construction: Thick fiberglass insulators, all-stainless steel hardware and 6063 aircraft-aluminum tubing is double or triple walled at key stress points to handle anything Mother Nature can dish out.

31.5 feet tall, 25 lbs. Mounting mast 1.25 to 2 inches. Wind surface area is 4 square feet.

R8, $539.95. Like R9 antenna but less 75/80 Meters.

R-8TB, $79.95. Tilt-base lets you tilt your antenna up/down easily by yourself to work on.

R-8GK, $59.95. Three-point guy kit for high winds.

Unrest in South Sudan Silences Ham Operators

The two licensed amateurs in South Sudan both report that they have taken their stations off the air and shipped their equipment out of the country "in order to avoid misunderstandings" with either side in the growing ethnic conflict that as of late December had claimed over a thousand lives. According to a report on the ARRL website, Massimo Stella, Z81B (also IZØEGB), and Diya al Asadi, Z81D (YI1DZ), said they expect to be off the air "for a while." Stella was in Europe while al Asadi remained in South Sudan. Both of them had been part of the Z81X operation from South Sudan in November, along with *CQ* DX Editor Wayne Mills, N7NG, who reports on that expedition and associated activities in his column this month (see page 94; note that Wayne filed his column prior to the outbreak of violence in the country).

Communications Act Update Planned

Citing the need for the law to keep pace with rapidly changing communications technology, the two Congressmen in charge of telecommunications policy in the House of Representatives say they are planning a comprehensive review and update of the Communications Act. Representatives Fred Upton (R-MI), Chairman of the House Energy and Commerce Committee, and Greg Walden, W7EQI (R-OR), Chairman of the Communications and Technology Subcommittee, say the effort will take over a year. Walden said the Communications Act, first passed in 1934 and last updated in 1996, is now "painfully out of date" and said the committee's goal is "to make sure this critical sector of our economy thrives because of the laws around it, not in spite of them." No timeline was given in the committee's announcement.

Listen for W100AW

The ARRL has been authorized by the FCC to use the special callsign W100AW during 2014, the League's centennial year. According to the *ARRL Letter*, the special call will be used in addition to W1AW, depending on the circumstance. Contacts made from the Maxim Memorial Station at ARRL Headquarters will use W100AW, as will those from regional conventions and during the IARU HF Championship this summer. However, regular bulletins and code-practice transmissions will still use W1AW, as will stations operating in the "W1AW WAS" program from each of the 50 states.

Solar Scientists: Cycle 24 Weakest in a Century

The current solar cycle is the weakest of the past ten cycles, according to four solar scientists reporting on "space weather" at the fall meeting of the American Geophysical Union. The *ARRL Letter* reports that the four—Nat Gopalswamy and Martin Mlynczak of NASA, Stanford's Leif Svalgaard and Joe Giacolone of the University of Arizona—say a weak polar magnetic field during Cycle 23 is thought to be the mechanism behind the weakness of Cycle 24. By continuing to track the polar magnetic field, said Svalgaard, it should be possible within a few years to predict the robustness (or lack of robustness) of Cycle 25. The group did not directly address the impact of the current weak cycle on radio propagation.

Hams Say "HI" to Juno Spacecraft

Hams around the world made coordinated transmissions last fall on 10 meters, sending "HI" in very slow Morse code to the sensors on the Juno spacecraft as it swung past Earth for a gravity boost on its journey to Jupiter. A video on the activity has been produced by NASA's Jet Propulsion Laboratory and is available on YouTube at <http://bit.ly/18PeGcI>. A more detailed article on the activity is planned for the March issue of *CQ Plus*.

Radio Arcala Tower Collapses in Storm

The massive 330-foot tower supporting the 160- and 80-meter Yagis at Radio Arcala's OH8X contest station in Finland collapsed under high winds in an early December storm that left some 200,000 families in the country without power. The 3-element 160-meter beam was reportedly the world's largest amateur radio antenna.

According to the *ARRL Letter*, group spokesman Jarmo Jaakola, OH2BN, speculated that the automation designed to enable the array "to find its most comfortable position in high winds" may have locked up and caused the structure to corkscrew. Jaakola said the tower—featured on the cover of the November 2011 cover of *CQ*—collapsed "peacefully" and caused no damage to any people or surrounding structures. At press time, inspectors were still trying to determine the exact cause of the failure.

Voice of Russia Leaves Shortwave

Many hams who came of age during the Cold War recall listening to the thinly disguised propaganda broadcasts of Radio Moscow booming in on their shortwave receivers. After the fall of the Soviet Union, the station was renamed the Voice of Russia but maintained a busy shortwave broadcast schedule. It began cutting back last year, though, and as of January 1, 2014, eliminated all shortwave broadcasting. The station will continue to reach out to international audiences via medium-wave broadcasting and the internet.

Astronaut-Hams Fix ISS Cooling System

Two American astronaut-hams repaired the International Space Station's cooling system during a dramatic Christmas Eve spacewalk, replacing a failed ammonia pump. According to *Newsline*, astronauts Mike Hopkins, KF5LJG, and Rick Mastracchio, KC5ZTE, each took two spacewalks as part of the repair mission, removing the faulty pump on December 21st and installing a new one on the 24th. The astronauts were outside the station for more than seven hours, in part because an ammonia fluid line sent frozen flakes of the substance right at them, with some sticking to their spacesuits. They had to wait until the ammonia on their suits dissipated before re-entering the station to avoid possible contamination.

In a related story, the *ARRL Letter* reports that former astronaut Susan Helms, KC7HNZ, has renewed her interest in amateur radio, regaining both her license and her callsign, which she'd allowed to expire in 2005. Helms, a Lieutenant General in the Air Force, is now the senior officer at Vandenberg Air Force Base in California. Her interest reportedly was reignited by an activity hosted by the Satellite Amateur Radio Club, W6AB, for Scouting's 2013 Jamboree on the Air. During a tour on the International Space Station in 2001, Helms used NA1SS for the first ARRL Field Day operation from space.

Ham Industry Changes

News of note from the ham radio industry:

• UK-based InnovAntennas has acquired Force 12 antennas of Bridgeport, Texas and consolidated its manufacturing activities with InnovAntennas America's facility in Grand Junction, Colorado. According to the InnovAntennas Facebook page, the combined facility "is in full swing and we are shipping, building and shipping antennas … daily."

• At the end of December, Japanese amplifier manufacturer Tokyo Hy-Power filed for bankruptcy and closed its manufacturing plant near Tokyo. The company's main website has also been closed down, although its US website remains active. According to a report on the ARRL website, company President and CEO Nobuki Wakabayashi, JA1DJW, said "the recent depression in the industrial RF power products area has led to the very difficult financial position."

• CQ Communications has realigned its publication lineup, merging *Popular Communications, CQ VHF* and *WorldRadio Online* into *CQ Plus*, a supplement to the digital edition of this magazine, effective with this issue. See "Zero Bias" on page 8 for more information.

Additional and updated news is available on the Ham Radio News page of the CQ *website at <http://www.cq-amateur-radio.com>. hy-gain Antennas and Rotators

HF Verticals

Work amazing DX with these extremely low radiation angle omnidirectional antennas. All self supporting, 1500 Watts PEP SSB, low SWR. Heavy duty, slotted, tapered, swaged, aircraft quality aluminum tubing. Stainless steel hardware. Two year limited warranty.

AV-680, $549.95. 9 Bands: (6,10,12,15,17,20,30,40, 80 Meters). 26 ft., 18.5 lbs. *Our most popular vertical now has 75/80 Meters! Lets you work exciting DX with a low 17 degree radiation angle!* Easily mount on decks, roofs, patios. *No ground or radials needed.* Extra wide 2:1 SWR bandwidths. *Each* band tunable. Auto bandswitching, handle 1.5kW, 80 MPH wind survival, low 2.5 sq. ft. wind surface. Aircraft aluminum tubing, stainless steel hardware.

AV-640, $449.95. Like AV-680 less 80M. 25½', 17½ lbs.

AV-620, $349.95. Like AV-640 less 40M. 22½'/10½ lbs.

AV-14AVQ, $179.95. (10, 15, 20, 40 Meters). 18 ft., 9 lbs. *Classic* AV-14AVQ uses same trap design as famous Hy-Gain Thunderbird beams. 3 air dielectric Hi-Q traps with oversize coils give superb stability and 1/4 wave resonance on all bands. Automatic bandswitching.

AV-12AVQ, $139.95. (10, 15, 20 Meters). 13 ft., 9 lbs. Lowest priced *automatic bandswitching* tri-band vertical! Uses Thunderbird beam design air dielectric traps for extremely hi-Q performance in limited space.

AV-18VS, $119.95. (10,12,15,17,20,30,40,80M). 18 ft., 4 lbs. Hy-gain's *lowest priced vertical* gives you 8 bands. Easily tuned to any band by adjusting base loading coil.

See our website for even more hy-gain vertical antennas!

HF Beams

Hy-gain beams are *stronger, lighter, have less wind surface and last years longer.* **Why?** *Hy-gain* uses durable *tooled* components -- massive boom-to-mast bracket, heavy gauge element-to-boom clamps, thick-wall swaged tubing -- no failures!

TH-11DX, $1159.95. 11-element, 4.0 kW PEP, 10,12,15,17,20 Meters. *The choice of top DXers.* With 11-elements, excellent gain and 5-bands, the super rugged TH-11DX is the *"Big Daddy"* of all HF beams! Features low loss log-periodic driven array on all bands with monoband reflectors, BN-4000 high power balun, corrosion resistant wire boom support, hot dipped galvanized and stainless steel parts.

TH-7DX, $869.95. 7-Element, 1.5 kW PEP, 10,15,20 Meters. 7-Elements gives you *the highest average gain of any Hy-gain* tribander! Dual driven for broadband operation without compromising gain. SWR less than 2:1 on all bands. Combined monoband and trapped parasitic elements give you an excellent F/B ratio.

TH-3MK4, $469.95. 3-Element, 1.5 kW PEP, 10,15,20 Meters. Gives most gain for your money in full-power, full-size *hy-gain* tri-bander! Impressive gain and a *whopping* average front-to-back ratio and still fits on an average size lot. 95 MPH wind survival.

TH-3JRS, $359.95. Compact 3-Element, 600 W PEP, 10,15,20 Meters. *Hy-gain's most popular and lowest-priced tri-bander fits smallest lot,* 14.75 ft turning radius, 21 lbs. Excellent gain and front-to-back let you compete with the "big guns"! 80 MPH wind survival.

hy-gain Rotators . . . the first choice of hams around the world!

HAM-IV . . . $649.95

The most popular rotator in the world! For medium communications arrays up to 15 square feet wind load area. *New* 5-second brake delay! *New* Test/Calibrate function. *New* low temperature grease permits normal operation down to -30 degrees F. *New* alloy ring gear gives extra strength up to 100,000 PSI for maximum reliability. *New* indicator potentiometer. *New* ferrite beads reduce RF susceptibility. *New* Cinch plug plus 8-pin plug at control box. Dual 98 ball bearing race for load bearing strength and electric locking *steel* wedge brake prevents wind induced antenna movement. North or South center of rotation scale on meter, low voltage control, max mast size of 2 1/16 inches.

HAM-VI, $749.95. For medium arrays up to 15 sq. ft. wind load. Like HAM-IV but has *new* ***DCU-2*** *Digital Rotator Controller*. Just dial in your beam heading or let your computer control your antenna.

HAM-VII, $799.95. Like HAM VI but with ***DCU-3*** digital controller with *six programmable memories*.

Tailtwister T-2X . . . $799.95

For large medium antenna arrays up to 20 sq. ft. wind load. Choose ***DCU-2*** *digital* controller (T-2XD2) or *analog* control box (T-2X) with *new* 5-second brake delay and *new* Test/Calibrate function. Low temperature grease, alloy ring gear, indicator potentiometer, ferrite beads on potentiometer wires, *new* weatherproof AMP connectors plus 8-pin plug at control box, triple bearing race with 138 ball bearings for large load bearing strength, electric locking *steel* wedge brake, N or S center of rotation scale on meter, low voltage control, 2 1/16" max. mast.

T-2XD2, $899.95. Tailtwister with ***DCU-2*** *digital* controller.

T-2XD3, $949.95. Tailtwister with ***DCU-3*** digital controller with *six programmable memories*.

AR-40, $349.95. For compact antenna arrays and FM/TV up to 3.0 sq. ft. wind load. Dual 12 ball-bearing race. Fully automatic.

CD-45II, $449.95. For antenna arrays up to 8.5 sq. ft. Bell rotator design gives total weather protection. Dual 58 ball bearing race.

Digital Rotator Controller with *6 Programmable beam headings*

New!

DCU-3

$449.95

New DCU-3 Digital Controller lets you program 6 beam headings! Gives you fully automatic or manual control of your hy-gain HAM or Tailtwister Rotators.

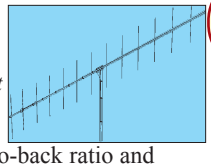
Push a memory button or dial in your beam heading or let *Ham Radio Deluxe* (or other program) control your DCU-3. Your antenna automatically rotates precisely and safely to your desired direction.

hy-gain VHF/UHF Antennas

V2R, $109.95. 2-Meter *vertical* has two *in-phase* 5/8 Wave collinear radiators for exceptional high omnidirectional gain. It has two sets of quarter wave radials that decouple radiator from mast. Covers 138-175 MHz. SO-239, handles 500 Watts. 9 feet.

V4R, $109.95. UHF *vertical*. Like V2R but covers 400-475 MHz. Type N, handles 500 Watts, 4 foot.

V42R, $169.95. *Dual band* covers 144/440 MHz bands. Two 5/8 Wave collinears.



VB-214FM, $89.95. *14-element* 2-Meter FM *beam* antenna provides exceptional front-to-back ratio and maximum obtainable gains.

VB-23FM, $49.95. 3-element.

VB-25FM, $59.95. 5-element.

VB-28FM, $79.95. 8-element.

Threaded stub for feedpoints. Accepts up to 2 inch mast.

DB-2345, $89.95. Dual band 144 (3-elements) 440 (5-elements) MHz.

System Fusion

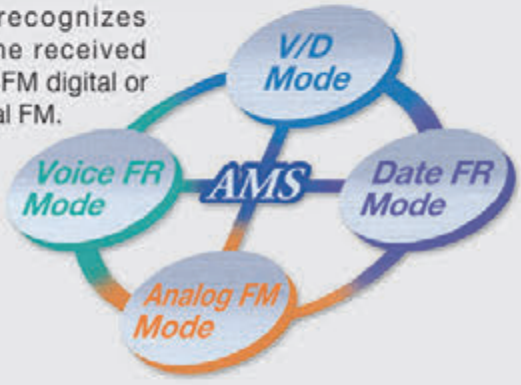
Get the Integrated Solution

System Fusion provides total integration of Digital and Conventional FM

System Fusion delivers integrated operational functionality that enables you to communicate with other Amateur Radio operators using conventional FM mode while you enjoy advanced digital communication features, such as image, text data and GPS position data using C4FM digital. System Fusion is designed to enable seamless communication between conventional FM and C4FM Digital Communication using a single unified platform.

AMS (Automatic Mode Select)

- Instantly recognizes whether the received signal is C4FM digital or conventional FM.



FM Friendly Digital

- System Fusion can be used in multiple ways, for digital communication, for conventional FM communication and even internet communication.

New Functions Enabled by C4FM Digital Communication

Digital Group Monitor (GM) Function

- Automatically checks whether members registered to a group are within the communication range.

Snapshot Function (Image Data Transmission)

- Image data can be sent easily to other C4FM FDMA digital transceivers.
- Image data can be displayed on the screen. (FTM-400DR ONLY)

Smart Navigation Function

- Real-time navigation function enables Location checking at any time.
- Backtrack function for returning to your departure Point.

zero bias – a CQ editorial

BY RICH MOSESON,* W2VU

CQ Plus – We're Changing to Better Serve You

How did you get started in the radio hobby? Did you dive right into ham radio, or did you start out doing something with an easier learning curve, such as shortwave listening or CB? Do you still enjoy some of those other aspects of hobby radio?

I certainly didn't start out in the deep end of the pool. I got started at about age 10, lying in bed late at night, listening to faraway AM broadcast stations in between the locals and trying to figure out where they were. This was followed by cold winter nights sitting in the family car, after I realized that the car radio was more sensitive than the old tube set in my bedroom (and had an external antenna outside the house, but I didn't know about that stuff yet). Then came CB, shortwave listening and finally, ham radio. I still dabble in SWLing and like to listen to airplanes and local public safety folks on my scanner.

I don't think my experience is at all uncommon. Most every ham I've ever met got started in a different branch of the radio hobby and worked his or her way up to the ranks of a licensed amateur. Do you still enjoy other parts of the radio hobby? I'm guessing yes. That's why virtually every HF transceiver on the market today includes a general coverage shortwave receiver, and why virtually every VHF/UHF transceiver includes wide coverage receive and scanning capabilities. We have collectively demanded it because we don't want to be limited by edges of the ham bands.

Very few of us are one-dimensional radio hobbyists. Yes, we may have a favorite part of the hobby, but most of us keep our fingers in other parts as well. Yet, hobby radio magazines have tended to be one-dimensional, specializing in one aspect of the hobby or another. Our focus in *CQ* has always been nearly exclusively on amateur radio, while our sister magazines have focused on other areas, either the broader listening part of the radio hobby or even narrower interests, such as contesting or VHF/UHF hamming. But no one magazine is really meeting all of your radio needs.

Well, we're about to change that. We're returning to the pre-1945 days of our predecessor magazine, *Radio*, and transforming *CQ* into your one-stop support center for all types of hobby radio!

Introducing *CQ Plus*

Beginning this month, selected content from our three sister publications, *Popular Communications, CQ VHF* and *WorldRadio Online*, will be incorporated into *CQ*'s digital edition as a supplement to be called "*CQ Plus.*" Take a look at our expanded table of contents (appearing in the print issue as well as the digital edition) to see what new offerings we have for you this month, from an update on the state of AM broadcasting and the FCC's efforts to "fix" it to an interview with a pirate broadcaster who regularly runs for President! The best of all four of our magazines is now combined into one—this one!

For our print readers, nothing will change. You will be getting the same *CQ* you've always gotten, with the same great features and columns you've come to expect. Digital subscribers will get both the print content and *CQ Plus* in a seamless, expanded, digital edition. Subscribers to *Pop'Comm, WRO* and *CQ VHF* have had their subscriptions transferred to *CQ*, with specifics based on the type of subscription they've had (print or digital) and the value of the remaining issues. Questions should be directed to our circulation department at <circulation@cq-amateur-radio.com> or 1-800-853-9797.

Yes, there is also an economic component at play here. First of all—as we've said here before—even though ham radio is growing at a nice pace, we're not seeing those increased licensing numbers translating into growth in radio clubs, ARRL membership or *CQ* readership. All of these are stable, but not keeping pace with growth in the number of licensees. Beyond amateur radio, the number of shortwave broadcast stations on the air is steadily shrinking, as cash-strapped governments decide they can effectively communicate with the rest of the world via the Internet and satellite, and without needing to maintain and operate expensive radio transmitter sites. Scanning options are shrinking as well, as more public safety agencies encrypt their (now mostly-digital) communications in the name of added security.

The bottom line for us is that *CQ* has been subsidizing *Pop'Comm, WRO* and *CQ VHF*. We can't continue to do that. Add in the glacial pace of the overall economic recovery and this has resulted in the delivery delays of both print and digital editions that have frustrated us as much as they have frustrated all of you. We are looking forward to a bigger, better, more comprehensive, *CQ* bringing us greater stability while continuing to serve our loyal readers throughout the radio hobby. We greatly appreciate your patience and your support as we have navigated these choppy waters, and we welcome the readers of *Pop'Comm, WRO* and *CQ VHF* to the pages of *CQ* and *CQ-Plus.* And speaking of which…

QRP Special

This month's issue is our annual **QRP Special**. We're focusing this year on the wide variety of ham radio activities that fall under the low-power umbrella, from operating QRP during lunch to using digital modes that copy signals you can't even hear! Of course, we've got non-QRP articles as well, from N2IRZ's column on how to build an inexpensive software-defined receiver to N2GA's fascinating suggestion that we try to make contesting a spectator sport as well as a participation sport.

A Sad Note

It is with great sadness that we pass along the news that former *CQ* Editor and CQ Amateur Radio Hall of Fame member Arne Trossman, W4EIP (ex-W2DTJ), became a Silent Key in November. In addition to his time at *CQ* (1960–64), Arne helped develop the Cosmophone, an early amateur SSB transceiver.

On a personal level, Arne was one of my first ham radio "Elmers" or mentors. I grew up a couple of towns away from Arne and he was my Radio Merit Badge counselor when I was a Boy Scout. I still remember going down to his basement ham shack and workbench, where he taught me to solder and helped me learn Morse code. It wasn't until many years later that we made the connection, realizing it was his work with a kid trying to earn a merit badge that set me on the path to eventually become his successor in the *CQ* editor's chair. 73, Tross. We'll miss you.

73, Rich, W2VU

Welcome Once Again to the Fun World of QRP Operating!

BY CAM HARTFORD,* N6GA

Hello, and welcome to *CQ*'s third annual QRP Special edition! The first QRP Special was published in April 2012, the second in March 2013, and this year we find ourselves in February 2014. Management at *CQ* Central deemed the forward creep of one month a year a necessity to accommodate scheduling changes in contest reporting . I suspect that it's something entirely different—that it's really the pressure of the QRP world wanting to make itself known. As I noted two years ago, there are QRP contesters, DXers, SSBers, digi-ops, home-

*1959 Bridgeport Ave., Claremont, CA 91711
e-mail: <qrp@cq-amateur-radio.com>

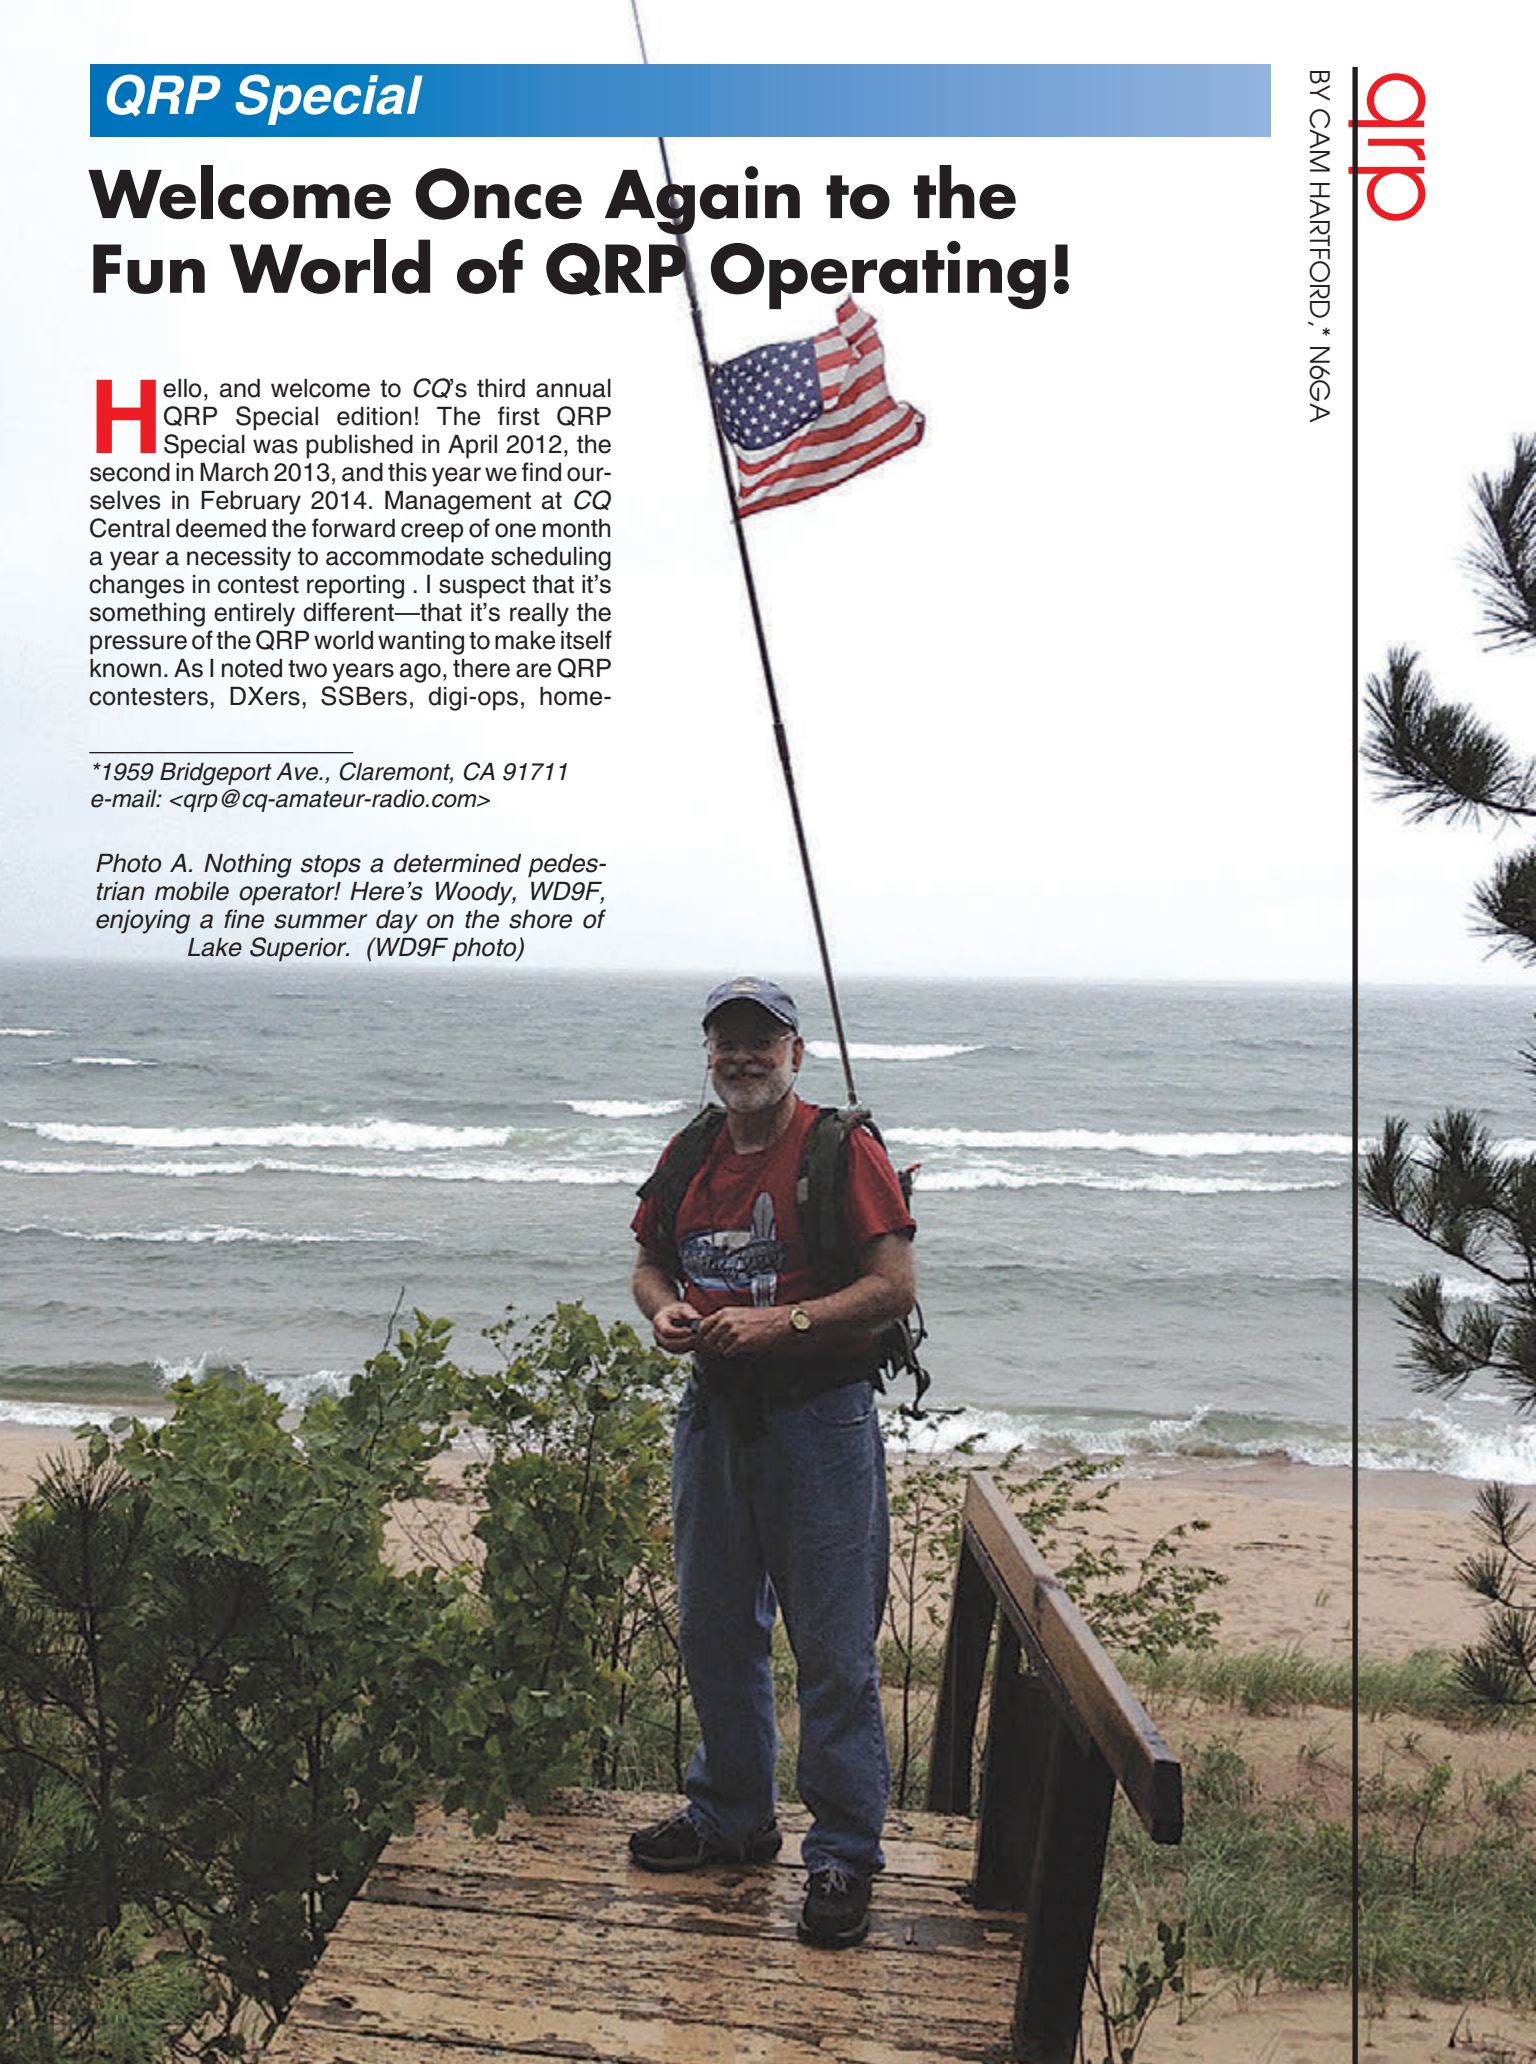

Photo A. Nothing stops a determined pedestrian mobile operator! Here's Woody, WD9F, enjoying a fine summer day on the shore of Lake Superior. (WD9F photo)

brewers, kit-builders, to-the-fielders, SOTAers, park-bench operators, fox chasers, net QNIers, and ragchewers. Oh yes, don't forget the pedestrian mobile ops. Read on!

Walkin' and Talkin'

I recently received this report from Woody Hester, WD9F (photo A). It seems Woody was bitten by the pedestrian mobile bug, and after an initial shakedown cruise has been stepping out in fine P/M style. Here's Woody's account:

Photo B. WD9F's p/m rig. (WD9F photo)

"After hearing Ed Breneiser's (WA3WSJ) excellent presentation on QRP pedestrian mobile operation at Four Days in May 2012, and having worked the amazing 'Father of /pm operation,' Paul Signorelli, WØRW, operating pedestrian mobile in three different states (Colorado, Florida, and Texas) over the last few years, I just had to give this QRP/pm thing a go.

"I bought a like new ALICE Pack frame on eBay, an antenna mirror mount at a truck stop near my home, and then began attaching the needed items to the pack frame to make up my /pm station (see photo B). What did we ever do without bungie cords?"

Fortunately, Woody has graduated to a hybrid mounting system which incorporates both bungie cords and zip ties. I'm not a big fan of bungies, having seen too many accidents where bungies sprung when it was least convenient, but at least in this case there's nothing more at risk than a few radio bits.

Woody continues: "I ended up using an MFJ 9020 transceiver for 5 watts on 20 meters, a 5-amp/hour SLA battery, an LDG auto tuner, and my Palm mini paddles. For my antenna, I attached a Hustler mobile antenna with a 20-meter resonator and included a 14-foot drag wire (24-gauge black silky from The Wireman). Total height is right at 12 feet.

"My first outing started in my Central Illinois backyard. ... I then proceeded out onto the nearby Sangamon Valley Bike Trail, and in about an hour of walking, I netted five solid QSOs. Tom, KM4CU, in Jax, Florida gave me a 559; Jean, VE2JCW, near Montreal gave me a 579; John, KN5L, in Austin, TX a 539; Michel, VE2TH, in Quebec running a new KX3 a 559; and Christian,VE1/F8BMG, running an IOTA station in the St. Lawrence a 579."

Wow, nice run of contacts for a first outing! It's hard to believe that a person can reach that diverse a crowd with such a small antenna and low power, but as Dave Ingram, K4TWJ (SK), used to say, "QRP Rocks!"

Here's a little more detail on Woody's /pm setup: "It's all built on an "ALICE Pack" frame. 'Alice' stands for 'all-purpose lightweight individual carrying equipment'. It's the pack frame that was adopted by the U.S. Army as the new standard in 1972 or so. It's made out of aluminum, it's strong, and it really is light weight. The pack frame can be had on eBay almost any day for around $20 plus shipping. I also bought two optional aluminum shelves specifically designed for the ALICE frame. They

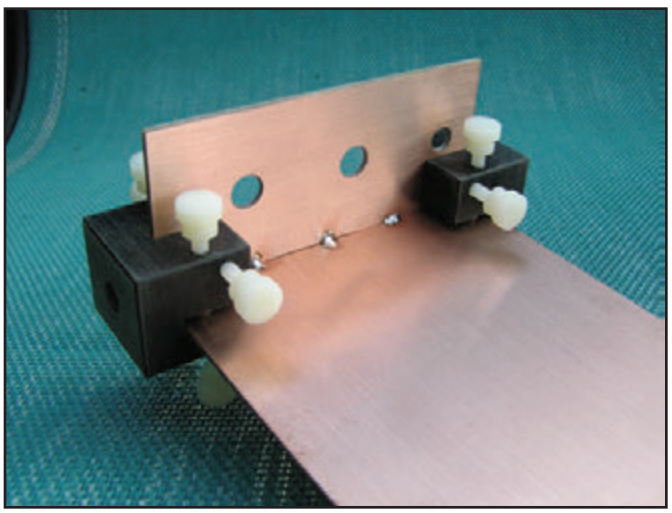

Photo C. A pair of SBSSs from QRPme hold this front panel in place while it's being soldered to the cabinet bottom.

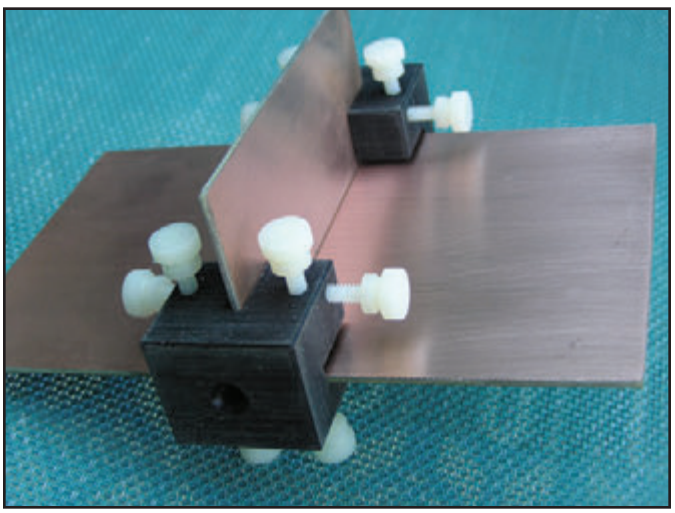

Photo D. Here the SBSSs are holding an interior shield in place for soldering.

were about $10 each on eBay and they really make it easy to attach things. ... Things I've learned on the trail are that I can always make contact with someone. Getting up high helps, too. We have a small hill (no mountains here in the flatlands) about a mile away, and when I get up on that it helps. The noise level drops way down when I get away from civilization and I hear very weak signals I don't normally hear. People watch me closely. Some ask what I'm doing, but most don't. They just give me a wide berth and keep moving. I always smile real big and give them a thumbs up. I do have to watch for overhead objects/tree branches, I carry a couple of extra drag lines in case one gets pulled off and I don't notice, and my earbuds and palm mini paddles are just perfect for this application."

This past summer Woody and his wife traveled to the southern shore of Lake Superior. "Yep, I took my pedestrian mobile gear along and spent several enjoyable hours hiking along the beach. The included picture was taken on a cold and windy day with light rain blowing horizontally down the beach. I still made several contacts. Highlights of my trip were two /pm to /pm contacts. One with Paul Signorelli, WØRW, who was /pm in Colorado; and Ed Breneiser, WA3WSJ, another widely acclaimed and accomplished /pm op who was pedestrian mobile on Pikes Peak. Ed had gone to Colorado from his home in Reading, PA to see the sights, operate pedestrian mobile, and visit Paul Signorelli. ... These contacts weren't planned. They took place on different days and just happened. I was thrilled. Paul had a great 589 signal from me, gave me a 559, and Ed and I were 559 to each other, all on 20 meters. That's my workhorse band for /pm. It's always open to somewhere. There's always someone around the QRP/SOTA watering holes, and my /pm antenna really likes it. I also worked Steve Galchutt, WGØAT, of Rooster and Peanut fame. Steve was at home in Colorado trying out his brand new ATS 4."

It sounds like Woody is now a true convert to world of QRP/pedestrian mobile. If you hear him around 14060, be sure to give him a call. He's probably out on the trail, ducking low-hanging trees and making QRP Qs!

Passing the Torch in the Northeast

A visit to the Small Wonder Labs website <http://www.smallwonderlabs.com/> yields a farewell message from Dave Benson, K1SWL, proprietor. It's not really a surprise, as Dave has been busy building his retirement home in the woods of New Hampshire while slowly reducing his involvement in kit production. Over the past 20 or so years the QRP community has benefited greatly from Dave's offerings. In this shack alone I can lay my hands on several SWL kits, including an early 2-board 20-meter transceiver that appeared in the *ARCI QRP Quarterly* from January 1993, an NN1G 20-20, a 20-meter DSW, a Warbler, a White Mountain SSB rig, and a couple of Rockmites. I even

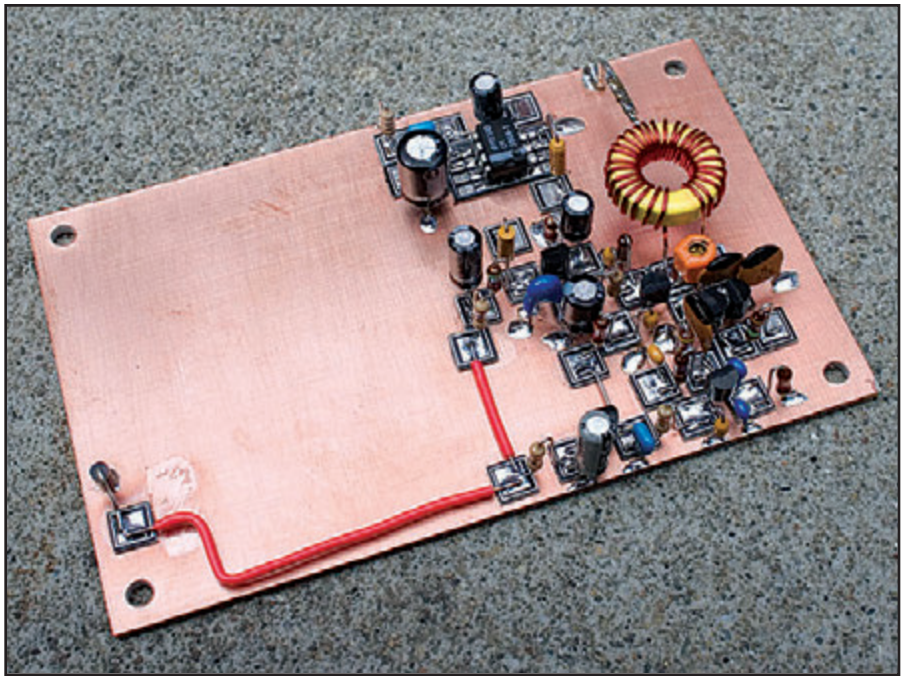

Photo E. Dave, AA7EE, used both MePADs and MeSQUAREs in this Manhattan project. Along the top edge of the board is an LM-386 soldered to a MePAD designed for an 8-pin IC. (AA7EE photo)

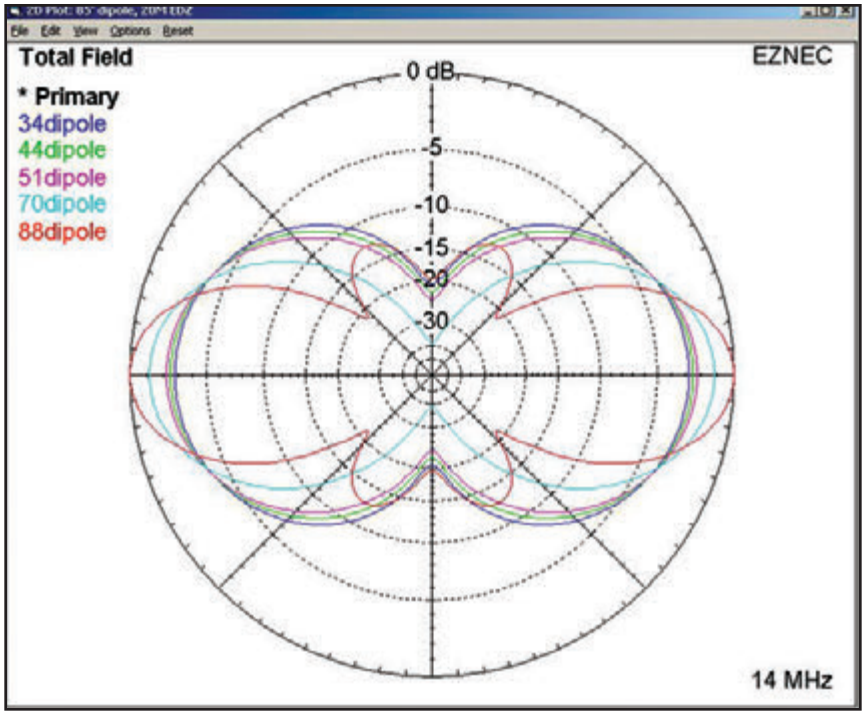

Fig. 1. EZNEC plots of several lengths of dipoles, all at 60 feet elevation and driven at 14 MHz.

have an 80-meter transceiver that I built from scratch from an article Dave published in the October 1991 issue of the *QRP Quarterly*. Thus, I hate to see Dave go. We all benefited greatly from his kits and support over the years, but he deserves a well-earned rest.

But wait! A little bit of Small Wonder Labs lives on! Rex Harper, W1REX, of QRPme (http://www.qrpme.com), the Tuna Tin place, has picked up the RockMite design and will continue to sell the very popular little rig. According to Rex: "The Small Wonder Labs RockMite design grew out of K1SWL's desire to offer a one-evening CW transceiver kit that would be both affordable and easy to construct. ... It appeared in *QST* magazine in 2003, and since then, it's been wildly successful. Approximately 8000 of these have been fielded so far!" Rex and Chuck Carpenter, W5USJ, have done some updating to the design, including bringing it up to current FCC requirements for harmonic suppression.

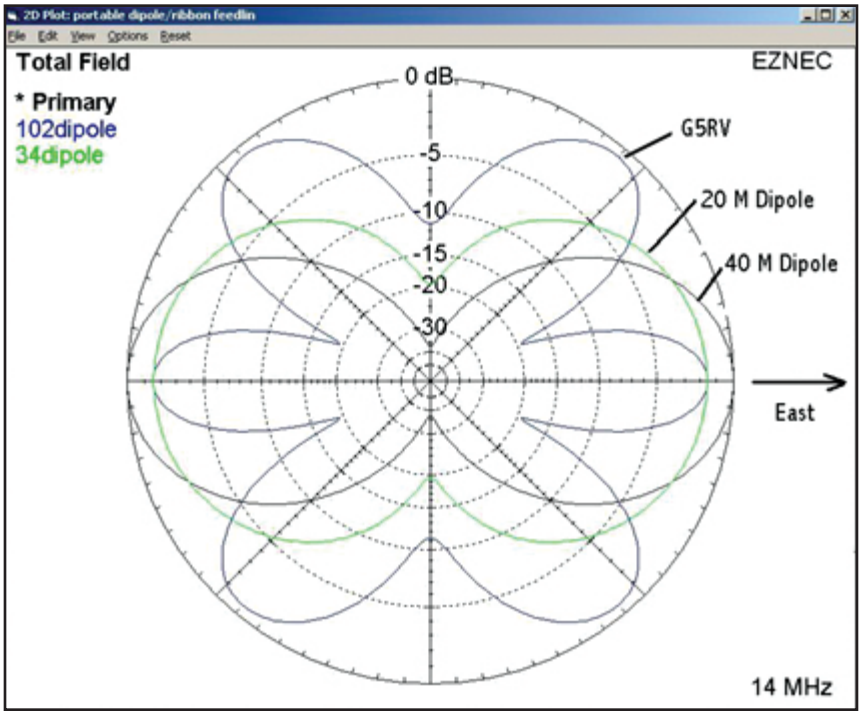

Fig. 2. Plots of a G5RV, 20- and 40-meter dipoles. Notice the difference between the lobes of the G5RV and the 40-meter dipole in the direction of interest.

More QRPme Bits

I was wandering around Rex's website and came across something I'd never seen before. They are called the "SBSS" which stands for—oh, I don't really know—maybe Solder Bot Square Something. Anyway, I saw these and immediate administered myself a thump on the forehead. Brilliant idea! Why didn't I think of that? There are lots of reasons which we won't waste time discussing here. Photo C shows a pair of the little things holding together a couple of pieces of PC board material ready for soldering. They hold the pieces at right angles so you can concentrate on doing the soldering ,and, hopefully, your chances of coming up with a straight, square enclosure for your next project will be greatly enhanced. You can also use them for making Tee joints, as in photo D, if you have the need to place a shield somewhere inside the box.

Also worth checking out are Rex's MePADS and MeSQUARES. (See photo E.) These little bits are made for the homebrew enthusiasts who favor the Manhattan style of construction. The sheet of Squares snap apart into hundreds of pre-tinned pads that you only have to glue down. Also, each Pads sheet consists of 28 pre-etched IC pads that you can snap apart and glue down. As Rex says, "They make it 'wicked easy' to mount both DIP and SOIC integrated circuits in your project." Photo E is an in-process shot taken by Dave Edwards, AA7EE, of a regenerative receiver he was making with the use of MePADS and MeSQUARES. Check out <http://aa7ee.wordpress.com/2011/07/24/the-wbr-a-simple-high-performance-regen-receiver-for-40m-by-n1byt> for an in-depth look at this homebrew project!

A Tale of Two Dipoles

Last September a couple teams of QRPers assembled with the intent of competing with the big boys in the CW Ops Open. The CW Ops run a couple of short sprints each month as well as an annual competition called the Open. You can find all the info about this organization at <http://www.cwops.org/>. Hank Greeb, N8XX, rallied the troops for this venture, and I have to say, fielding a team of Davids to take on the Goliaths is a bunch of fun. We never hurl a big enough rock to do serious damage, but we do place well enough to show what QRP can do.

What distinguishes this contest from many others is that there is an effort to include CW ops from around the world. Total operating time is 12 hours, but that is broken up into three 4-hour sessions timed for good propagation in Europe, Asia, and the Americas. For those of us in the Pacific time zone that means session One is from 5 to 9 PM Friday evening, session Two is from 5 to 9 AM Saturday morning, and session Three is from 1 to 5 PM Saturday afternoon. Taking into account the oddball session times and the fact that some local noise source had been making life very miserable at my home QTH, I made the decision to flee to the local mountains and do a portable setup. There might be fewer honey-do's up there, too.

This would be like a mini Field Day but without the crack team of experienced antenna erectors. I'd have to do this on my own, limiting me to fairly simple antennas. A 120-foot tower with stacked Yagis would be an excellent choice, but not this time. It was looking like I'd have to fall back on that dependable workhorse of antennas, the dipole.

From southern California most of the country is centered around an azimuth of 75 degrees, Europe is about 30 degrees and JA is at about 320. However, the sunspots had been puny in the days leading up to this contest and the outlook for DX was rather dim so I chose to optimize the antennas for in-country use. I could put up two, one aimed across the country and another aimed north-south so as to pick up the western states.

The next question facing me was exactly what dipole to use. Twenty meters would be the bread-and-butter band, but after dark 40 and even 80 came into play. There also could be some action on 15 meters, complicating the decision.

I lined up the usual suspects, which

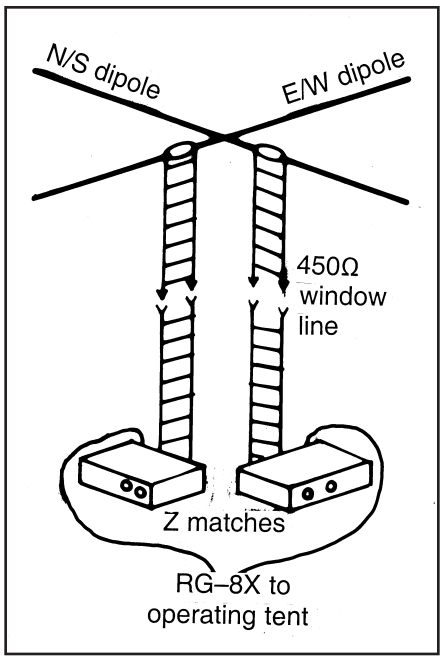

Fig. 3. Layout of the David vs. Goliath antenna farm.

were, from smallest to largest, 34 feet, 44 feet, 51 feet, 70 feet, 88 feet, and 102 feet. The smallest one is a 20-meter dipole, which would work fine for 20 and 15 but not for the lower bands. The 44 is known as a "Half 88." I believe L. B. Cebik popularized these sizes as usable for multi-band dipoles when fed with ladder line. The 51-footer is known as a "Half G5RV" for obvious reasons. The 70-foot antenna is a 40-meter half-wave dipole. The 88 foot antenna is, coincidentally, an Extended Double Zepp on 20 meters.

Fig. 1 is a composite of the radiation patterns of each one of these antennas on 14 MHz, all at a height of 60 feet. I've left off the G5RV for the sake of clarity. The 34-foot antenna shows the classic pattern of a half-wave dipole. As we lengthen the wire, two things happen: The gain in the lobe increases, while the width of the lobe, or its beamwidth, decreases. From the 34- to the 44- to the 51-foot dipole you can see a slight lengthening of the lobe (increasing gain), while at the same time the beamwidth narrows slightly. There's not a lot to choose from amongst these three antennas, as the gains are all within 1 dB of each other. There's a noticeable jump when we go to the 40-meter dipole, however, at 70 feet in length. Here the gain over the 20-meter dipole is about 1.6 dB and the beamwidth is noticeably narrower.

Referring back to fig. 1, the 88-foot antenna also shows a substantial jump in the gain, but once again at the expense of beamwidth. The Extended Double Zepp is a significant length for a dipole, because at 1.25 wavelengths, it's the longest dipole that exhibits its maximum directivity broadside to the wire. Any longer and the main lobes start to shrink and the little side lobes grow, spreading your power in many points around the compass.

The G5RV, at 102 feet, would have been a good antenna for 40 and 80 meters, but on 20 meters the main broadside lobe has shrunk to a skinny little thing. See the plots in fig. 2. This shows the G5RV, 20- and 40-meter dipole plots. On 20 meters, there's lots more signal headed across the country using the 40 meter dipole. However, I noticed something interesting about this antenna. The two biggest lobes are at about 40 degrees either side of the axis of the wire, meaning that if I needed to head for the hills for a DX contest I could conceivably put up a G5RV with the wire on a north-south axis and the big lobes pointed at Europe and Asia. Food for thought.

In the end, I chose to use the 40-meter dipoles. At 70 feet long this antenna is resonant on 40 meters and has some gain and directivity on 20 meters. The EDZ would have had more gain but at the expense of beamwidth. Additionally, on 15 meters at 88 feet of length the major lobes split to form an almost

CQ 2014-15 calendar

15 months of value
January 2014 through March 2015

$10.95 plus shipping

Fifteen spectacular color images of some of the biggest, most photogenic shacks and antennas from across the country and...*new this year*... a number of DXpedition and classic radio shots thrown in for good measure!

Calendars include dates of important Ham Radio events, major contests and other operating events, meteor showers, phases of the moon, and other astronomical information, plus important and popular holidays. CQ's 15-month calendar (January 2014 through March 2015) is truly a must have!

HAM IT UP! — AMATEUR RADIO — A NATIONAL RESOURCE

NEW!

THE OPUS OF AMATEUR RADIO KNOWLEDGE & LORE

Written by Eric Nichols, KL7AJ, with contributor Gordon West, WB6NOA, this is a fun look at why we're hams! The Opus is a tribute to the passion and poetry of Amateur Radio. It informs the newcomer and also reminds the old timer about the magic and lure of a hobby that is both technical and artistic. If you love the smell of ozone, soldering flux, and overheating transformer varnish you're sure to enjoy Eric's book!

OPUS $19.95

NEW!

WORLDWIDE LISTENING GUIDE

John Figliozzi's brand new, expanded 6th edition *Worldwide Listening Guide* explains radio listening in all of today's formats – "live," on-demand, WiFi, podcast, terrestrial, satellite, internet, digital and, of course, AM, FM and SW. Includes a comprehensive program guide to what can be heard how, when and where. Link to WWLG website keeps you up-to-date on program schedule changes. Spiral bound to open in a flat, easy-to-use format. Order today for Holiday delivery.

USING YOUR METER

Teach yourself the correct use of your multitester. Book explains fundamental concepts of electricity including conventional and electron current and series and parallel circuits. It teaches how analog and digital meters work and tells you what the voltage, current and, resistance measurements mean. Then it provides fully-illustrated, step-by-step instruction on using your meter in practical applications in the home, workshop, automotive and other settings. An excellent learning tool and reference for the hobbyist and ham.

perfect clover leaf, aiming a nice deep null across the country. It's never helpful to have your antenna aimed at every place but where the potential contacts are! Even the 40-meter dipole scatters the 15-meter signal around, but with two antennas at right angles I was able to get a lobe aimed sufficiently well to snag plenty of 15-meter Qs.

Having the two dipoles set at right angles covered the country pretty well. The patterns of the antennas overlapped somewhere in the direction of the Dakotas on both 40 and 20 meters. Switching between the two with the A/B antenna switch confirmed this. Mother Nature was thoughtful with her tree placement, so I was able to get the antennas up within about two degrees of perpendicular. This is necessary to minimize coupling between the antennas and hence skewing of the patterns. I fed both antennas with 450-ohm window line down to ground level, where I had a pair of homebrew Z-match tuners, and from there ran coax into the operating tent. Here the two coaxes went into the A/B antenna switch.

With this setup I had 40, 20, and 15 covered pretty well, but not 80 meters, and 80 would provide plenty of Qs if there were an easy way to incorporate it. The problem with running 80 meters on a 40-meter dipole is one of efficiency. The 40-meter dipole will radiate a signal on 80 meters, but the feedpoint impedance is highly reactive with a low resistive component. This will result in substantial feedline loss, even if you are using ladder line. Recommended reading on the subject is this page from the W8JI website at <http://www.w8ji.com/short_dipoles_and_problems.htm>. Modeling the 40-meter dipole on 80 meters in EZNEC shows a feedpoint impedance of 14.6 – j1110 ohms. Using the VK1OD transmission line loss calculator referenced by W8JI <http://vk1od.net/calc/tl/tllc.php>, we find the loss on the line to be 5.5 dB. Add to that another dB or so of loss in the tuner and the 5 watts coming out of your transmitter shrinks to 1 watt by the time it reaches your antenna.

What to do? I cut two pieces of wire 20 feet long. On each one I soldered a big alligator clip to one end and tied a 10-ounce fishing sinker on the other. When it came time on Friday night to change bands to 80 meters, I dropped one of the dipoles and clipped one of the wires to each end; the resulting antenna looking like an upside-down U. The resulting antenna was 110 feet long, so the feedline loss was substantially less. Something closer to four watts was actually making it to the feedpoint. Unfortunately, I hadn't visualized making this change after dark so things didn't work exactly as planned. When I hauled the antenna back up after clipping on the end wires, one end got tangled in an antenna-eating tree and all operations stopped for a good half hour of yanking and swearing by the puny beam of a flashlight. I got back on the air with 7 minutes left in the session and had a total of three 80-meter QSOs to show for it. *Note to self:* Visualize things better!

There were lots of lessons learned in this venture. The 40-meter dipoles worked well for the bands and the directions I wanted to cover. The 80-meter extensions would have served well but for what we'll call "cockpit problems." Most importantly, a high dipole can be a very effective antenna and shouldn't be overlooked if you are going out on a Goliath-slaying venture! (See fig. 3.)

Sign-Off

Thanks for riding along on this QRP adventure. Fun as it may be, nothing beats the real thrill of getting on the air and doing it yourself! 72/73, Cam N6GA

No time to get on the air? Consider W2LJ's approach to squeezing some quality QRP DXing into his busy day.

QRP à la Carte

BY LARRY MAKOSKI,* W2LJ

For those of us still actively participating in the workforce, it's a common tale of woe: Between full-time employment (in some cases, more than one job), kids' activities, civic or church responsibilities, home improvement tasks, house chores, etc., what time is left for amateur radio? By the time I get home from work, eat dinner, walk the dog, and do whatever other chore I have in front of me, I'm ready for bed ... not the shack! Weekends can be even worse with the myriad of home-improvement projects and yardwork tasks that seem to never end. What's an avid QRPer to do?

Fortunately, I have an hour thrust upon me each day which provides a little "off" time. That hour, otherwise known as lunchtime, has become a golden opportunity for getting in some QRP time. Instead of sitting in the cafeteria, or at my desk with a sandwich while absentmindedly gazing at YouTube, you will find me on the air, either scanning the bands or pounding out a CQ.

Quick Setup and Teardown

The key to successful lunchtime QRP operation is quick setup, easy-to-operate equipment, and quick disassembly when you're done. You don't want to spend your time fussing with equipment while you could be making contacts. If your setup is a permanently mounted mobile HF rig, that's all the better. Hopefully, you can turn your power output down to 5 watts and take off running. However, if you just tote along some QRP gear in a backpack like I do, then there are some considerations that must be made.

The first major consideration: From where will you operate? Your options may or may not be limited. If you're fortunate enough to work very close to a public park, this can be a perfect place to set up (photo A). At my last job, I had a park only five minutes away. I was able to get there, set up, and operate within a very reasonable amount of time (photo B). Others are not so lucky. In this case, you may want to consider just going out to your car in the company parking lot and setting up from there (photo C). Your circumstances will dictate your setup.

Antenna Choices

The next consideration is what to use for an antenna. While it has to be a com-

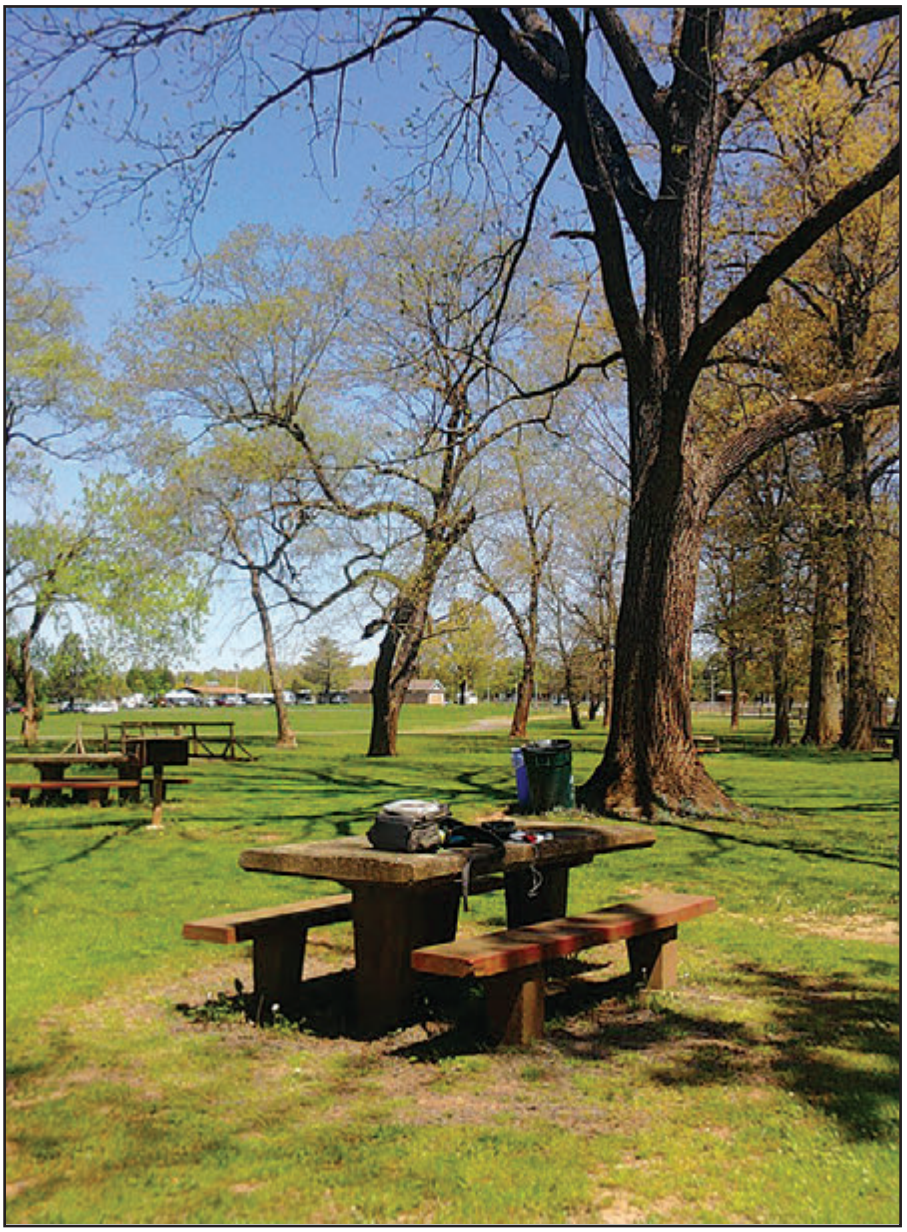

Photo A. A picnic table can make an ideal lunchtime operating position, if you're lucky enough to work near a public park. (Photos by the author)

*e-mail: <w2ljqrp@gmail.com>

Photo B. No picnic table? Try operating from your car. In this photo, we see a quick-setup antenna supported by a mast with a baseplate that sits underneath a tire.

promise for quick setup for a short portable operation, you do want it to be somewhat efficient. There's no fun in trying to make contacts while sending your 5 watts into a dummy load. Over the years, I have tried many different solutions. Your chosen operating location will influence your choices. Operating from a picnic table in a park will give you more options. Remembering that limited lunchtime is a factor, you may want to just heave an end-fed wire up into a tree. An end-fed such as the commercial PAR ENDFEDZ or a home-made end-fed using a 31-foot length of wire to a 9:1 UNUN is perfect for this type of operation. I have also put up an end-fed where no trees were available by using a 31-foot Jackite pole as a temporary mast.

If your operations are going to be confined to a parking lot, your options are probably going to be more limited, but in no way does this mean you cannot be successful. I used Hamsticks on a mag-mount for years and was somewhat successful.

Just this past year, I was turned onto an even better solution by my good friend Bob Reisenweber, W3BBO. We both own Buddisticks. I had always used mine in the conventional manner, attaching it to a tripod or painter's pole, unwinding the counterpoise wire and going from there. Bob suggested a different approach. He was living in an apartment at the time and was limited to working from his car. He took

Photo C. Can't get away to a park to operate? Your company's parking lot might be an effective spot from which to operate, especially if you have a roof-mounted antenna.

Photo D. A Buddistick attached to a heavy-duty magnet mount can be a very effective antenna that's quick to set up and tear down. Also, no counterpoise is needed as long as your vehicle has a metal roof.

his Buddistick to his car in the lot and attached it to his car's mobile antenna mount (photo D). I tried it and had great success! Not only is it a quick and easy setup and tear-down, but by its very nature, the Buddistick is oriented towards multiband operation. Changing a tap on a coil when changing bands is so much easier than changing individual resonators, and the car provides a very nice ground plane for the antenna. No counterpoise wire is needed with this set up.

Selecting a Rig

As far as rig choice goes, there are many available to you as a QRPer. Just about any of the commercially offered QRP rigs, or any of those offered as kits, can be operated from the field quite easily. Toss one in a case, along with a key or microphone and a battery, and you are good to go. My weapon of choice is the Elecraft KX3. I use a Whiterook single-lever paddle, some earbuds, and a small 9800 mAH lithium-ion battery. It makes for a perfect portable station, light and easy to carry in a Lowepro 150 travel case (photo E).

The results have been fantastic! I can get into my car, break out my KX3, set up the Buddistick, and be on the air within mere minutes. For 40 meters, I don't tap the Buddistick's coil. For 20, 17, 15, 12, and 10 meters, I have found one tap position that allows the KX3's internal tuner to work effortlessly with the Buddistick.

Since last April, I have over 160 QSOs with this setup, making CW contacts using 5 watts or less with 48 different DX entities, 19 states, and 5 SOTA (Summits on the Air) peaks.

Photo E. The author's lunchtime-portable QRP station, built around his Elecraft KX-3 transceiver.

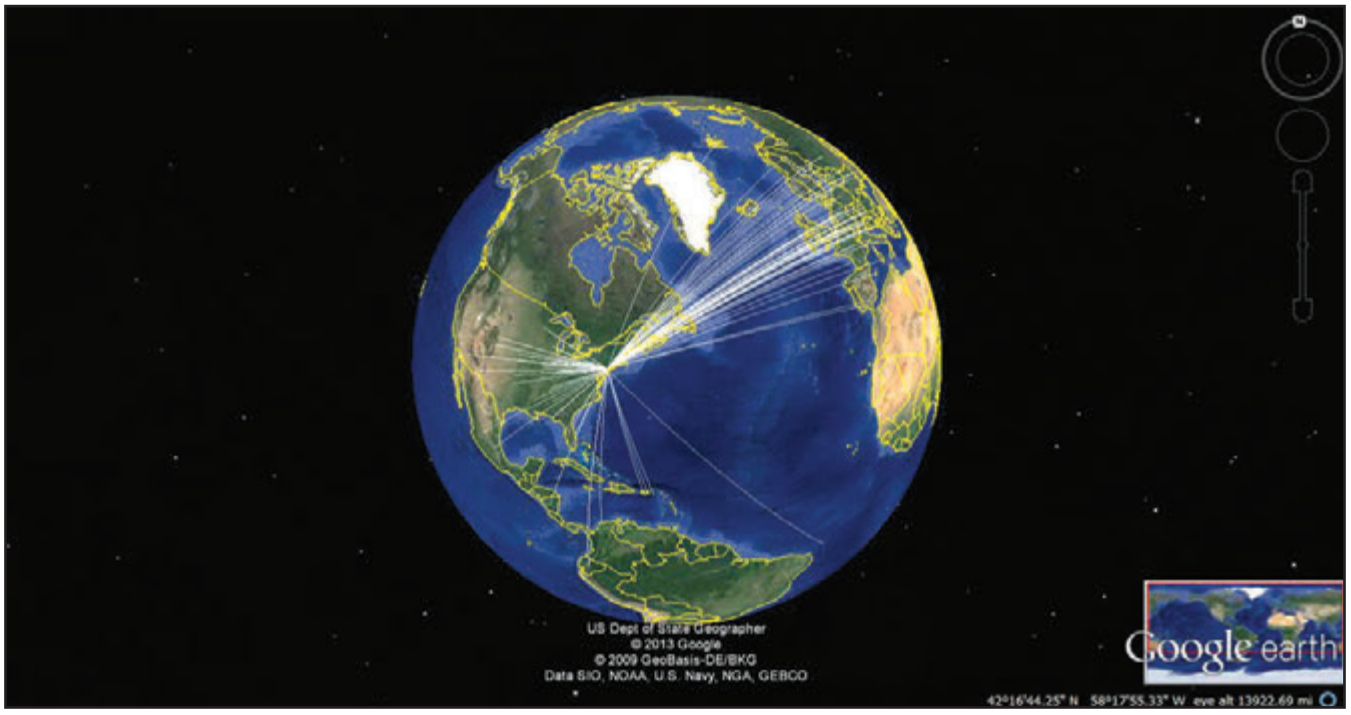

Photo F. A Ham Radio Deluxe overlay of W2LJ's 2013 lunchtime contact paths on a Google Earth® map. This view shows the contacts from a western hemisphere perspective.

Contacts are routinely made with stations 6,000 and 7,000 miles away, easily achieving the 1,000-mile-per-watt category. My most distant contact so far has been with R6YY at the eastern edge of European Russia at 8,522 miles. Photos F and G are screen-shots from my computer showing contact paths overlaid on Google Earth® maps by Ham Radio Deluxe.

Staying Sane

Even though lunchtime is limited, you can make a lot of contacts and more importantly you can have a lot of fun. I sometimes kid with my ham friends that if it weren't for lunchtime, I'd never get on the air at all. This hour has been my salvation. It supplies my daily needed fix of QRP, it breaks up my day, and it helps keep me sane. If you are in the same situation that I am, you should give this a try. You'll be glad you did and you just might be amazed by your results.

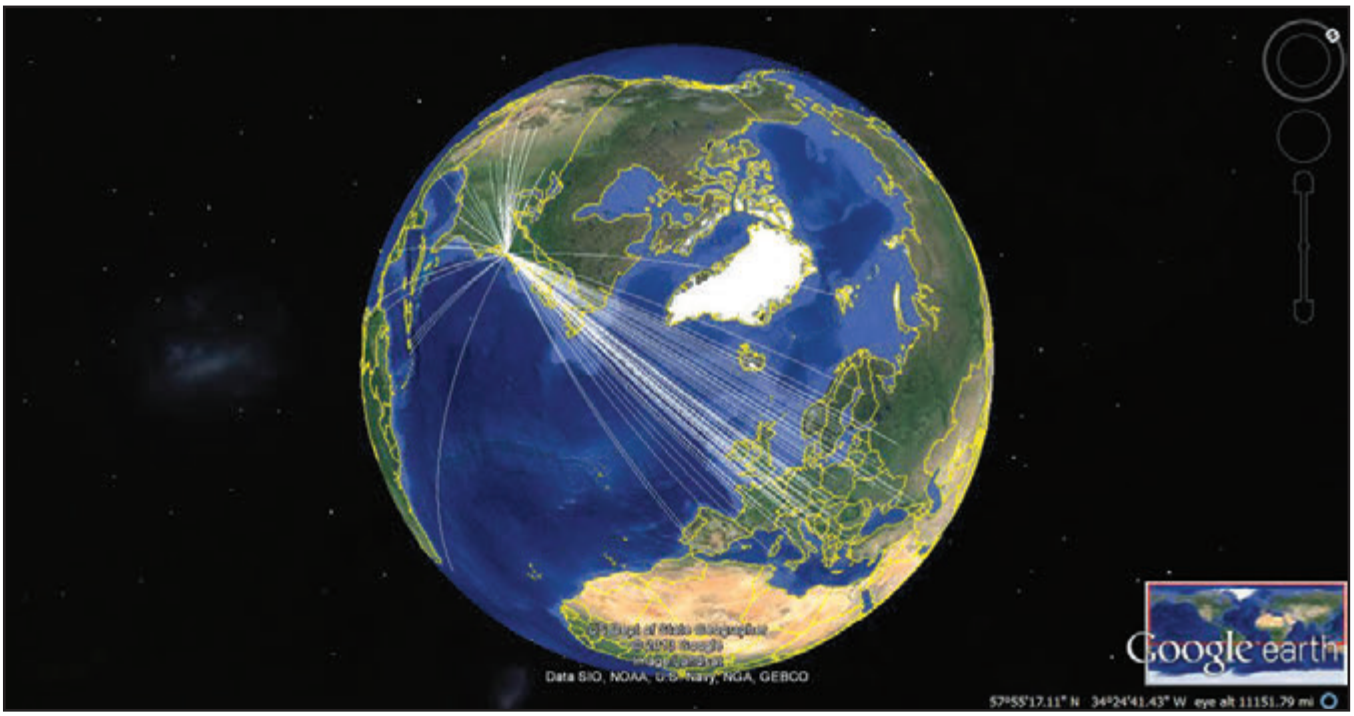

Photo G. The same contact paths as shown in photo F seen from an eastern hemisphere perspective. Five watts can travel quite a long way!

What at first seemed to the author like "a painful process" rutned into an adventure in learning while collecting contacts with all 50 states using just one-tenth of a watt.

Worked All States with 100 Milliwatts

BY JOHN WATKINS,* NØEVH

Working all 50 states with an accumulated power of 5 watts or an average of 1/10 watt for each state... I had heard of amateurs achieving this goal, but it sounded like a painful process that certainly one would not consider as part of an enjoyable hobby. But here I am…

It started innocently for me back in May of 2003 when I worked a killer-signal station in Michigan from my home state of Missouri on 40 meters. K8CV was so very strong into my QTH, and since Walt normally operated QRP, I thought the band must be in great shape. I quickly dropped my power to 1/10 of a watt and gave him a call. We continued our QSO with no problem.

With my courage up, I looked around 20 meters for a strong signal and worked a Virginia station within the hour, still at 100 milliwatts. Going to higher frequencies always helps the low-power enthusiast because of a better signal-to-noise ratio. I'm not sure whether I was lucky or if the bands were just amazing, but I began to watch for unusually strong signals from stations and to make note of how much power they were running.

Photo A. The author at his station in Missouri. His Elecraft KX-3 (lower right, behind pad) was his main "weapon" in contacting all 50 states at a power level of 1/10 of a watt.

Antenna Experiments

I recently had moved my vertical antenna from a ground mount to a chimney mount and noticed some improvement in performance. I did not have anything to compare it with, so I decided to install a horizontal 80-meter loop so that I had a choice between a vertical and a horizontal antenna. The average height of my loop was 25 feet, all I could muster in my yard. I began to compare antennas and was pleased to find that the loop was a killer antenna in close on 80 and 40, easily beating the vertical. Then on the upper bands—20 and above—the loop actually performed slightly better than the vertical. I about wore out my A/B antenna button the next few years doing comparisons. I feed the loop with 450-ohm ladder line back to the shack and through a 4:1 balun to my rig. As the experiments continued, my states total continued to grow.

I did not pursue the goal hard, just let it happen over the years whenever I heard great band conditions. Along the way, I hit a couple of fantastic openings and finally worked Hawaii and Alaska on 10 meters at the end of a contest when stations were hungry for contacts and had no answers to their CQs. You probably know the callsigns if you're a contester; those guys have excellent stations and copying skills. The 80-meter loop was my go-to antenna on about 90 percent of my Qs. So now I had the hard ones in the log, right?

Not really. The hard ones sometimes are the close ones or those with fewer ham radio stations on the air. Most of these states are close to my home QTH in Missouri (photo A), so I had a double-whammy. What to do?

I wanted to add 160 meters to my bands, so I went with the only antenna that would fit in my lot. It was an inverted L at 30 feet and the horizontal portion even had a dogleg in it because of my small lot. Thinking that I now had added a band, I was amazed when the inverted L began to beat out my 80-meter loop on some stations. I was feeding the L with a 9:1 balun, had two 80-foot above-ground radials attached at the ground feed point, and they ran around the house on the wooden hardscape. It was not ideal by the antenna book, but it sometimes beat the loop. I have now had the loop for ten years and the L for four. They split the very low-

*16805 Erin Ln., Independence, MO 64055
e-mail: <n0evh@sbcglobal.net>

power contacts at 50% each. I think it depends upon incoming/outgoing take-off angle of the signal.

The Hunt Begins in Earnest

Now that I had some success, I wanted to pursue some competitive stations and add to my state count. I felt the close-in states would be worked on 40 and 80 meters, so I needed to chase states during the winter months when thunderstorms were not raising the noise floor. Avoiding the QRN would go a long way to my signal being heard. Between my two best antennas—the loop and the inverted L—I figured that I could now present a decent signal on 80 through 10 meters. A few years passed and my total state count reached 40.

With the ARRL Sweepstakes contest coming in the fall of 2013, I checked the family calendar and discovered that I would have time to get on the air. Of my remaining ten states many were the small- or low-population ones. Checking the ARRL contest record website, I identified the top-scoring stations for those states and made my own personal hit list. I then set up CW Skimmer and married it to my Elecraft KX3 I/Q output so I could watch 48 kHz of whatever band I was on. This would give me an extra set of eyes trying to spot my targets. CW Skimmer produces a list that can be sorted by time, frequency, or callsign (see fig. 1), so when I took a stretch break, it was still watching for my targets. My final preparation step involved analyzing my logbook to see when I had heard my target states, on what bands and at what time of the day during the month of November. I now had a plan for working the Sweeps.

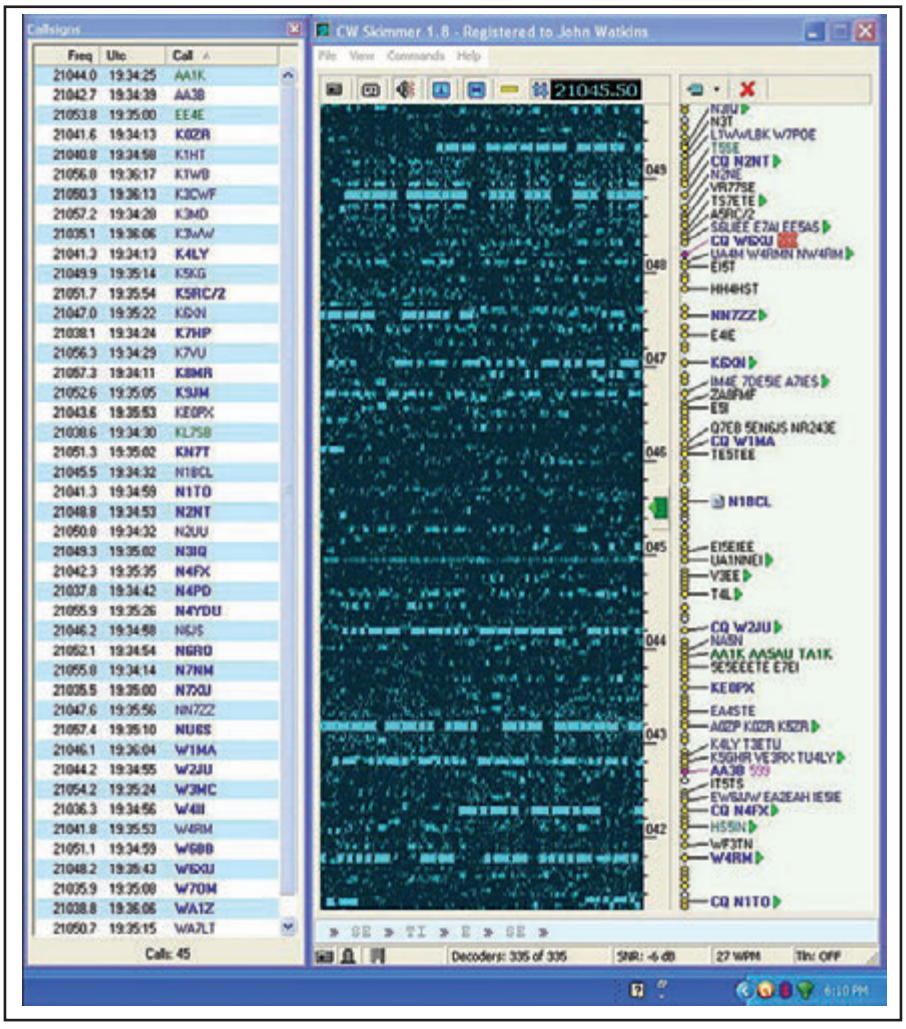

Fig. 1. Screen capture of CW Skimmer running on the right half of the screen. Taken during the heat of Sweepstakes action, you can see the list of stations that have been identified by the skimmer. They are sorted alphabetically by callsign.

Going All Out

On the first day of the contest, I jumped in with my 1/10 of a watt. In five hours I had logged eight of my ten target states with only two of them asking for repeats. Bands were in great condition and things were going very well. The fall weather and absence of thunderstorms across the nation were providing great signals and low QRN on 40 and 20 meters. States in the range of 400 to 600 miles—such as Indiana, Minnesota, and Oklahoma—were collected on 40. Kansas was logged on 80 in the early evening, before that band went long. The more distant states of New Mexico, Wyoming, and Montana were logged on 20.

To be heard at these power levels you need to call in the clear (no one else calling the CQing station) and have great propagation and low noise at the other end. Now only West Virginia and Delaware were needed in my log, but reaching the East Coast from the Midwest was not going to work for me for the rest of the evening. While 40 meters was in great shape and signals to me were strong, the band was wall-to-wall signals, so the QRM was too intense for my little signal. I would have to wait for West Virginia and Delaware. There would be less signal congestion on Sunday morning, I reasoned, so I pulled the plug for the night.

The Sweeps event has 83 sections and many stations want to collect them all for a "clean sweep." Others are going for the sweep plus high score. Thus, the odds were in my favor that on the second day the sweep hunters would have moved on to other targets.

One great feature of CW Skimmer beyond the obvious is that it calculates the signal-to-noise ratio of the station tuned. I was running power 30 dB below most stations in the contest, so I was looking for signals that were at least 40 dB above my noise. Of course, too, I was hoping that the noise level was also low at their end. No point in calling a station that can't hear you. Once you have found your target station, listen to him/her work through the callers. Watch the ebb and flow of the action. Every few minutes the CQing station will get a brief lull in activity. No callers. That is your opportunity, so be ready with your memory keyer set at his speed and make it happen. Don't use your key, as this is not the time to make mistakes.

The Final Two

The next morning, West Virginia was in my log on 20 meters by 10 AM. I tried to get his attention for one-and-a-half hours. His signal was holding just fine at 45 dB over the noise, so once the competition had been worked and he had few callers, he was mine. A final snack from the kitchen and then back

Fig. 2. Screen capture from RBN (Reverse Beacon Network) website showing a search on KH (* is a wildcard) for this search engine. This provides one method for finding active stations from a given part of the world or targeting a specific station with its callsign.*

to the bands. The only Delaware station I had spotted was doing search-and-pounce, so my progress was stalled. I scouted 10 meters for about an hour, but it became obvious that the east and west coast stations were working each other, not the "fly-over" states. I then dropped down to 15 meters and found that my Delaware target station had begun to call CQ. Got him in just a couple of minutes!

Ten years, three radios, and multiple antenna experiments, what fun it was along the way! And that tough Delaware station I finally found and logged; the morning after the Sweeps I got my confirmation for the QSO via Logbook of the World (LoTW)! Got to love electronic logging! For those who like stats, here are states per band: 10m-6, 12m-0, 15m-6, 17m-1, 20m-20, 30m-1, 40m-14, 80m-2, 160-0.

There were some interesting highlights recorded in my log during my 10-year adventure. Three states were worked when I was calling CQ with 1/10 of a watt. While working in the shack on a project I would put the rig on a slow CQ repeat and listen on an open frequency. Five additional states were logged while they were running 1000 watts, 40 dB above my station. They heard me on my first call in the clear. When Mother Nature gives you the reflection, you just have to be there! About half of my states were worked during casual non-contest periods, and it was always fun to chat with the other ham about low-power radio. One old timer said he had never worked a station at a tenth of a watt and asked me to stand by while he turned his QRO rig down to 5 watts to give QRP a try. Another ham in Washington had been a World War II Army radio operator and carried radio gear on mules. You just never know whom you will run into on the bands.

Your odds of being on the right band for those great reflections can be increased by using the *Reverse Beacon Network* (fig. 2). If you are collecting states and are not restricted by assisted rules in a contest, you simply do a search on KH* if looking for a Hawaiian station or KL* if Alaska is not in your log. Of course, in my case I was looking for known big-station contesters, so I searched their specific callsigns. No need to fish where there are no fish.

Preparing that target station list was also valuable because several big contest stations had callsigns out of their call districts. For example, I would have never taken a second look at an 8 station while searching for my 50th state of Delaware.

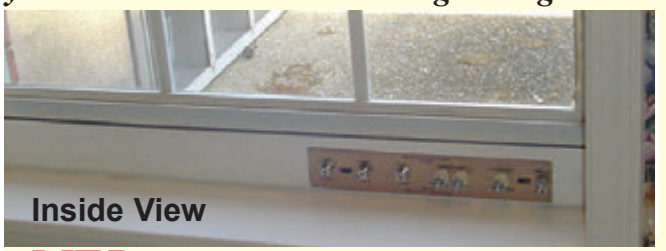
What's Next?

So what to do now? Well, I am still working on DXCC at 1 watt. Guess I will close that out this winter, then maybe start on DXCC at 1/10 of a watt, but oh, I already have. Along the way while working on my states goal, I worked 17 DX entities at a 1/10 of a watt, so here we go again!

By the way, as an extra benefit of running very low power, you will end up with some great antennas! The ones that are marginal will have been taken down and redesigned by the time you get your 50 states in the logbook. Give it a go and enjoy the journey at whatever power level you choose to set as your goal.

MFJ Weather-Proof *Window Feedthrough Panels*

Weather-proof window feedthrough panels bring coax, balanced lines, HF/VHF/UHF antennas, random wire antennas, ground, rotator/antenna switch cables and DC/AC power into your hamshack without drilling through walls!



MFJ Weather-Proof *Window Feedthrough Panels* mount in your window sill. Lets you bring all your antenna connections into your hamshack *without* drilling holes through walls.

Simply place in window sill and close window. One cut customizes it for any window up to 48 inches. Use horizontally or vertically. Connectors are mounted on inside/outside stainless steel plates and attached to a 4 foot long, $3^{1}/_{2}$ inch high, $^{3}/_{4}$ inch thick *pressure-treated* wood panel. Has excellent insulating properties. Weather-sealed with a heavy coat of long-lasting white outdoor enamel paint. Edges sealed by weather-stripping. Seals and insulates against all weather conditions. Includes window locking rod.

Inside/outside stainless steel plates ground all coax shields. Stainless steel ground post brings ground in.

MFJ-4603 Universal Window Feedthru Panel

MFJ-4603 **$89.95**

Four 50 Ohm *Teflon*(R) SO-239 coax connectors lets you feed HF/VHF/UHF antennas at full legal power limit.

A 50 Ohm *Teflon*(R) coax *N-connector* lets you use any antenna up to 11 GHz, including 450 MHz, UHF, satellite, moon bounce and 2.4/5.8 GHz Wi-Fi antennas.

A 75 Ohm, 1 GHz *F-connector* makes it easy to bring in television, Satellite, HD, cable TV and FM radio signals.

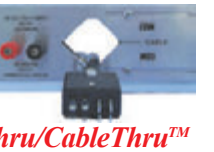
A pair of high-voltage *ceramic feedthru insulators* lets you bring in 450/300 Ohm balanced lines directly to your antenna tuner.

Has random/longwire antenna *ceramic feedthru insulator*.

***5-way** binding posts* lets you supply 50 Volts/15 Amps DC/AC power to your outside antenna tuners/relays/switches.

Stainless ground post brings in ground connection, bonds inside/outside stainless steel panels together and drains away static charges.

MFJ's exclusive *Adaptive Cable Feedthru*™ lets you bring in rotator/antenna switch cable, etc. without removing connectors (up to $1^{1}/_{4}$X$1^{5}/_{8}$ in). Adapts to virtually *any* cable size. Seals out rain, snow, adverse weather.



3 Coax, Balanced Line, Random Wire

Best Seller! 3 *Teflon*(R) coax connectors for HF/VHF/UHF antennas. Separate high voltage *ceramic* feed-thru insulators for balanced lines and longwire/random wire, Stainless steel ground post.

MFJ-4602 **$69.95**

6 Coax

6 high quality *Teflon*(R) coax connectors for HF/VHF/UHF antennas. Stainless steel ground post. Full 1500 Watt legal limit.

MFJ-4601 **$59.95**

4 Balanced Line, 2 Coax

4 pairs of high-voltage *ceramic* feed-thru insulators for balanced lines and 2 coax connectors.

New! MFJ-4600 **$79.95**

5 Cables, any-size

5 *Adaptive Cable Feedthrus*™. Pass any cable with connector: 2 cables with large connectors up to $1^{1}/_{4}$x$1^{5}/_{8}$ inches and 3 cables with UHF/N size coax connectors. Seals out weather.

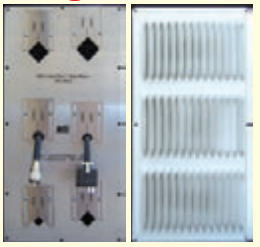
MFJ-4604 **$99.95**

All-Purpose FeedThru/CableThru™

***Stacks** MFJ-4603 **and** MFJ-4604!* Gives you every possible cable connection you'll ever need through your window without drilling holes in wall -- including UHF, N and F coax connectors, balanced lines, random wire, ground, DC/AC power and cables of any size for rotators, antenna switches, etc.

MFJ-4605 **$159.95** **New!**

Bring cables thru eave of your house



MFJ-4616 shown with standard full-size vent (not included) it replaces. For *6 Cables* **$26.95**

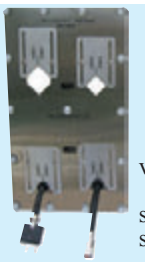
MFJ-4613 shown with standard half-size vent (not included) it replaces. For *3 Cables* **$14.95**

Replace your standard air vents on the eave/sofitt of your house with these *MFJ AdaptiveCable*™ *Air Vent Plates* and…

Bring in coax, rotator, antenna switch, power cables, etc. *with connectors* up to $1^{1}/4$x$1^{5}/8$ inches!

Sliding plates and rubber grommets adjust for virtually any cable size to seal out adverse weather, insects and varmints. Use existing vent hole, mounting screws and screw holes.

AdaptiveCable™ Wall Plates



MFJ-4614 *For 4 Cables* **$34.95**

Bring nearly any cable -- rotator, antenna switch, coax, DC/ AC power, etc. -- through walls *without removing connectors* (up to $1^{1}/_{4}$x$1^{5}/_{8}$ inches). Sliding plates and rubber grommets adjust hole size to weather-seal virtually any size cable.

Includes *stainless steel* plates for each side of wall, sliding plates, rubber grommets, weather stripping and screws.

MFJ-4612 *For 2 Cables* **$24.95**

MFJ-4611 *For 1 Cable* **$14.95**

Announcing:

The 2014 CQ World-Wide WPX Contest

SSB: March 29–30, 2014 CW: May 24-25, 2014
Starts: 0000 UTC Saturday Ends: 2359 UTC Sunday

I. OBJECTIVE: For amateurs world wide to contact as many amateurs and prefixes as possible during the period of operation.

II. PERIOD OF OPERATION: 48 hours. Single Operator stations may operate 36 of the 48 hours – **off times must be a minimum of 60 minutes** during which no QSO is logged. Multi-operator stations may operate the full 48 hours.

III. BANDS: Only the 1.8, 3.5, 7, 14, 21, and 28 MHz bands may be used. **Observance of established band plans is strongly encouraged.**

IV. EXCHANGE: RS(T) report plus a progressive contact serial number starting with 001 for the first contact. Note: Multi-Two and Multi-Unlimited entrants use separate serial number sequences on each band.

V. SCORING:

A. Score: The final score is the result of the total QSO points multiplied by the number of different prefixes worked.

B. QSO Points: A station may be worked once on each band for QSO point credit:

1. Contacts between stations on different continents are worth three (3) points on 28, 21, and 14 MHz and six (6) points on 7, 3.5, and 1.8 MHz.

2. Contacts between stations on the same continent, but different countries, are worth one (1) point on 28, 21, and 14 MHz and two (2) points on 7, 3.5, and 1.8 MHz. Exception: For North American stations only—contacts between stations within the North American boundaries (both stations must be located in North America) are worth two (2) points on 28, 21, and 14 MHz and four (4) points on 7, 3.5, and 1.8 MHz.

3. Contacts between stations in the same country are worth 1 point regardless of band.

C. Prefix Multipliers: The prefix multiplier is the number of valid prefixes worked. Each PREFIX is counted only once regardless of the band or number of times the same prefix is worked.

1. A PREFIX is the letter/numeral combination which forms the first part of the amateur call. Examples: N8, W8, WD8, HG1, HG19, KC2, OE2, OE25, LY1000, etc. Any difference in the numbering, lettering, or order of same shall count as a separate prefix. A station operating from a DXCC entity different from that indicated by its call sign is required to sign portable. The portable prefix must be an authorized prefix of the country/call area of operation. In cases of portable operation, the portable designator will then become the prefix. Example: N8BJQ operating from Wake Island would sign N8BJQ/KH9 or N8BJQ/NH9. KH6XXX operating from Ohio must use an authorized prefix for the U.S. 8th district (/W8, /AD8, etc.). Portable designators without numbers will be assigned a zero (Ø) after the second letter of the portable designator to form the prefix. Example: PA/N8BJQ would become PAØ. All calls without numbers will be assigned a zero (Ø) after the first two letters to form the prefix. Example: XEFTJW would count as XEØ. Maritime mobile, mobile, /A, /E, /J, /P, or other license class identifiers do not count as prefixes.

2. Special event, commemorative, and other unique prefix stations are encouraged to participate. Prefixes must be assigned by the licensing authority of the country of operation.

VI. ENTRY CATEGORIES:

A. Single Operator Categories: One person (the operator) performs all operating and logging functions. There is no limit on band changes. Only one transmitted signal is permitted at any time.

1. Single Operator: QSO alerting assistance of any kind is prohibited (see rule IX.2).

a. High Power (All Band or Single Band): Total output power must not exceed **1500 watts.**

b. Low Power (All Band or Single Band): Total output power must not exceed **100 watts.**

c. QRP (All Band or Single Band): Total output power must not exceed **5 watts.**

2. Single Operator Assisted: Entrants in this category may use QSO alerting assistance (see rule IX.E).

a. High Power Assisted (All Band or Single Band): Total output power must not exceed **1500 watts.**

b. Low Power Assisted (All Band or Single Band): Total output power must not exceed **100 watts.**

c. QRP Assisted (All Band or Single Band): Total output power must not exceed **5 watts.**

B. Single Operator Overlay Categories: Single Operator entrants may **also** submit their log for **one** of the categories shown below by adding an additional line in the Cabrillo log file header called CATEGORY-OVERLAY. All Overlay entries are grouped into high power and low power in the results.

1. Tribander/Single Element (TB-WIRES): During the contest an entrant shall use only one (1) tribander (any type, with a single feed line from the transmitter to the antenna) for 10, 15, and 20 meters and single-element antennas on 40, 80, and 160 meters.

2. Rookie (ROOKIE): To enter this category the operator must have been licensed as a radio amateur three (3) years or less on the date of the contest The date first licensed **must** be indicated in the SOAPBOX field. An operator who has won a plaque in any previously published CQ contest is not eligible for the Rookie category.

C. Multi-Operator Categories (All Band only): More than one person can contribute to the final score during the official contest period. Select category based on number of transmitted signals.

1. Single-Transmitter (MULTI-ONE): Only one transmitted signal is permitted at any time. A maximum of ten (10) band changes may be made in any clock hour (00 through 59 minutes). For example, a change from 20 meters to 40 meters and then back to 20 meters counts as two band changes. Use a single serial number sequence for the entire log.

a. High Power. Total output power of each transmitted signal must not exceed **1500 watts.**

b. Low Power. Total output power of each transmitted signal must not exceed **100 watts.**

2. Two-Transmitter (MULTI-TWO): A maximum of two transmitted signals is permitted at any time on two different bands. Both transmitters may work any station. A station may only be worked once per band regardless of which transmitter is used. **The log must indicate which transmitter made each QSO** (column 81 of CABRILLO QSO template for CQ contests). Each transmitter may make a maximum of eight (8) band changes in any clock hour (00 through 59 minutes). Use a separate serial number sequence for each band. Total output power of each transmitted signal must not exceed **1500 watts.**

3. Multi-Transmitter (MULTI-UNLIMITED): A maximum of six transmitted signals, one per band, at any one time. Six bands may be activated simultaneously. Use a separate serial number sequence for each band. Total output power of each transmitted signal must not exceed **1500 watts.**

D. Checklog: Entry submitted to assist with the log checking. The entry will not have a score in the results and the log will not be made public.

VII. AWARDS: A single-band log will be eligible for a single-band award only. To be eligible for an award, a Single Operator station must show a minimum of 4 hours of operation. Multi-operator stations must operate a minimum of 8 hours.

A. Plaques are awarded to recognize top performance in a number of categories. View the current list of plaques and sponsors at <www.cqwpx.com/plaques.htm>.

Only one plaque will be awarded per entry. A station winning a World plaque will not be considered for a sub-area award. That award will be given to the runner-up for that area if the number of entries justifies the award.

B. Certificates will be awarded to the highest scoring station in each category listed under Section VI:

1. In every participating country.

2. In each call area of the United States, Canada, Russia and Japan.

3. At the discretion of the contest director second- and third-place awards may be made.

VIII. CLUB COMPETITION: A plaque will be awarded each year to the club that has the highest aggregate score from logs submitted by its members. To be listed in the results, a minimum of three logs must be received from a club.

A. The club must be a local group and not a national organization (e.g., ARRL or DARC).

B. Participation is limited to members residing in or operating from a local geographic area (except for DXpeditions conducted by members living within the defined club geographic area). Club contributions from DXpedition scores are a percentage of the number of club members on the DXpedition.

C. Single-operator entries can only contribute to one club. Multi-operator scores may be allocated to multiple clubs as a percentage of the number of club members participating in the operation. A minimum of four logs must be received for a club to be listed in the results. Checklog entries are not counted for the club score.

IX. DEFINITIONS OF TERMS:

1. Station location: The area in which all the transmitters, receivers and antennas are located. All transmitters and receivers must be within a single 500-meter diameter circle. Antennas must be physically connected by RF transmission lines to the transmitters and receivers.

2. QSO alerting assistance: The use of any technology or other source that provides call sign or multiplier identification along with frequency information to the operator. It includes, but is not limited to, use of DX cluster, packet, local or remote call sign and frequency decoding technology (e.g., CW Skimmer or Reverse Beacon Network), or operating arrangements involving other individuals.

X. GENERAL RULES FOR ALL ENTRANTS:

A. Entrants must operate within the limits of their chosen category when performing any activity that could affect their submitted score.

B. A different callsign must be used for each entry. Only the entrant's callsign may be used to aid the entrant's score.

C. Do not exceed the total output power limitation of the chosen category on any band. Total output power on any band at any time is measured at the final output of the active amplifier(s).

D. Self-spotting or asking to be spotted is not permitted.

E. All operation must take place from one station location. Remote operation is permitted if the physical location of all transmitters, receivers, and antennas are at one station location. A remotely operated station must obey all station license, operator license, and category limitations.

F. Remote receivers outside the station location are not permitted.

G. Only one signal on a band is allowed at any time. When two or more transmitters are present on the same band, a hardware device MUST be used to prevent more than one signal at any one time. Alternating CQs on two or more frequencies on a band is not permitted.

H. All requests for contacts, responses to calls, and copying of call signs and contest exchanges must be accomplished during the contest period using the mode and frequencies of the contest.

I. Correction of logged call signs and exchanges after the contest by using any database, recordings, email or other methods of confirming QSOs is not allowed.

X. LOG INSTRUCTIONS: Electronic submission of logs is **required** for all entrants who use a computer to log the contest or prepare contest logs.

A. The log MUST show the following for each contact: correct date and time in UTC, frequency (or band), call sign of the station worked, exchange sent, and exchange received. A log without all required information may be reclassified to Checklog. Contacts should be logged immediately as they are completed. Stations competing for World and Continent awards should provide accurate frequencies for all contacts in the log.

B. Single band entrants are required to include all contacts made during the contest period, even if on other bands. Only contacts made on the band specified in the Cabrillo header or summary sheet will be considered for scoring purposes. Logs with contacts only on one band will be classified as single band entries.

C. The CABRILLO file format is the standard for logs. See <www.cqwpx.com/lcabrillo.htm> for detailed instructions on filling out the CABRILLO file header. Failure to fill out the header correctly may result in the entry being placed in the wrong category or reclassified as a Checklog. Note: U.S. stations must indicate the station location in the CABRILLO header (e.g., LOCATION: OH).

D. E-mail or Web upload is the expected method of log submission. SSB logs in CABRILLO format should be sent to <ssb@cqwpx.com>. CW logs in CABRILLO format should be sent to <cw@cqwpx.com>. Include only the entry call sign in the "Subject:" line of the e-mail. Web upload of logs is available at <www.cqwpx.com/logcheck/>. All logs received will be confirmed via e-mail. A listing of logs received can be found at <www.cqwpx.com>.

E. Instructions for NON-CABRILLO electronic logs: If you are not able to submit a CABRILLO format log, please contact the Contest Director for assistance with submitting another format.

F. Instructions for paper logs: Paper logs may be mailed to CQ WPX Contest, P.O. Box 481, New Carlisle, OH 45344, USA. Each paper log entry must be accompanied by a Summary Sheet listing all scoring information, the category of competition, and the entrant's name and mailing address in BLOCK LETTERS.

XI. LOG DEADLINE:

A. All entries must be emailed or postmaked WITHIN FIVE (5) DAYS after the end of the contest: SSB logs no later than 2359 UTC 4 April 2014, CW logs no later than 2359 UTC 30 May 2014 Resubmitting an entry after the deadline will result in it being considered as a late log.

B. An extension may be requested by e-mail to <director@cqwpx.com>. The request must state a legitimate reason and must be received before the log deadline. Extensions are granted only upon confirmation by the Contest Director.

C. Logs submitted or postmarked after the deadline may be listed in the results, but are not eligible for awards.

XII. JUDGING: The CQ WPX Contest Committee is responsible for checking and adjudicating the contest entries. Entrants are expected to follow the rules and best amateur radio practices. Violation of the rules of the contest or unsportsmanlike conduct may lead to disciplinary action by the Committee.

A. Unsportsmanlike Conduct: Examples of unsportsmanlike conduct include, but are not limited to:

1. ARRANGING or CONFIRMING any contacts during the contest by use of ANY non-amateur radio means such as telephones, Internet, instant messaging, chat rooms, VoIP, social media or web sites.

2. Transmissions by the entrant on frequencies outside of license limitations.

3. Changing times in the log to meet band change or off time rules.

4. Taking credit for excessive unverifiable QSOs or unverifiable multipliers.

5. Signals with excessive bandwidth (e.g., splatter, clicks) or harmonics on other bands.

6. Running stations making more than 3 contacts without sending their callsign.

B. Observer Program: The Committee may request of any entrant to accept a visit by an observer during the contest. Failure to allow a Committee appointed observer full access to the station during the contest period may result in the entry being disqualified.

C. Disciplinary Actions: In the event of a violation, the entrant is subject to disqualification at the discretion of the Committee.

1. DISQUALIFICATION: Entry will be listed at the end of the published results and is not eligible for an award.

2. Notification of Committee actions will be sent by email to the address provided with the log submission. The entrant has five days to appeal the decision to the Contest Director. After that time the decision is final.

3. An entrant may withdraw the submitted log for any reason within 30 days of the log deadline. Contact the Contest Director for instructions.

4. The Committee reserves the right to change the category of any entry based on its examination of the log or other information.

D. Log Checking: All logs are checked using custom software and human judgment.

1. Duplicate contacts are removed with no additional penalty.

2. Contacts with an incorrectly received exchange are removed with no additional penalty.

3. Call sign errors or call signs not found in the other log are removed and receive a penalty of two times the QSO point value for that contact.

4. Contacts that do not meet the band change rules for multi-operator entries are removed with no additional penalty.

XIII. DECLARATION: By submitting a CQ WPX Contest log, and in consideration of the efforts of the CQ WPX Contest Committee to review and evaluate that log, an entrant unconditionally and irrevocably agrees that he/she has: 1) read and understood the rules of the contest and agrees to be bound by them, 2) operated according to all rules and regulations that pertain to amateur radio for the station location, 3) agreed the log entry may be made open to the public, and 4) accepted that the issuing of disqualifications and other decisions of the Committee are official and final. If an entrant is unwilling or unable to agree to all of the foregoing, the entrant should not submit the entry or submit the entry as a Checklog only.

Questions pertaining to the CQ WPX Contest may be emailed to the CQ WPX Contest Director at <director@cqwpx.com>.

33 Simple Weekend Projects

by Dave Ingram, K4TWJ

Do-it-yourself electronics projects from the most basic to the fairly sophisticated. Practical tips and techniques on creating your own projects.

You may have heard about JT-65 for working moonbounce and meteor scatter. But what about JT-9, for working QRP on HF? Here's an introduction…

JT9: QRP with the Magic Multiplied

BY GARY LILJEGREN,* W4GAL

Operating with 100 watts of output power and bouncing a signal off the ionosphere when talking with stations thousands of miles away still seems amazing to me. I've done that for a long time. However, when I reduce the power level to one one-hundredth of that, and have many QSOs world-wide (photo A), that's beyond amazing; it's magic.

There is a relatively new mode available today that offers an opportunity for *multiplied magic*. The mode is *JT9,* created by Joe Taylor, K1JT, and friends. JT9 has been running on the bands a little more than a year. It functions a bit like PSK with an audio signal applied to SSB (upper sideband) in the CW portion of the bands.

Five Reasons Why the Magic is Multiplied

1. Surprising success operating QRP with results as if the "ERP" is considerably greater
2. Talking to stations that are below the noise level; they are inaudible in the speaker
3. The ability to easily have QSOs from any language to any other language
4. A perfect mode for a highly successful operation as a temporary or portable station
5. Visualizing the international reception results of your signal on a world map

Let's explain the magic of the five reasons:

1) FM and TV broadcast stations talk about their *effective radiated power* (ERP) in watts. The signal has been "amplified" at the receiving locations by the use of gain antennas at the transmitter. The ERP comparison is similar to JT9, but for a different reason. A near-broadcast-quality AM signal in ham radio is about 6,000 Hz wide. All of the transmitting power is going into that 6-kHz signal. On SSB, the signal is somewhere around 2,800 Hz wide and thus the ERP for SSB is maybe twice that of an AM signal. (An aside to you technically astute hams reading this: cut me a little slack on the technical specifics.) Without comparing other modes for efficiency, let's look at JT9. The width of the signal is about 16 Hz. That means the signal bandwidth is less than 1/100th that of an SSB signal. One watt on JT9 does somewhere

*e-mail: <gary@liljegren.com>

Photo A. The author's impressive station appears to have nearly as many computers in it as radios. (Photos by the author)

Photo B. Shirl Regis, W9OMG, operating JT9 at 5 watts with great results from her home in North Florida using an ICOM IC-718 and a temporary vertical antenna.

around the same job communicating information as a 100-watt SSB signal. QRP, enhanced! And this gets us to the next magic point.

2) When you hear the description of how JT9 works with very-weak stations (below), it won't sound possible at first to copy a station that is below the noise level. What Joe has done is apply the technology of weak-signal moonbounce and meteor-scatter data acquisition on UHF and VHF to the HF and MF bands. JT9 is intended for the latter two. He has created a way of transmitting and receiving minute changes of audio frequency to form letters and symbols. The transmitted signal is a steady tone but the audio pitch varies in frequency at specified intervals, depending on what the letter is. The WSJT-X software detects those audio changes when copying the transmission. The software also computes the received signal strength of the other station. When a contact is made, the software is brutally honest and displays the signal strength on the display operating panel in dBs. Joe says that if the signal is –15 or less, nothing is heard through the speaker; the received signal is inaudible. However, the software can copy it! I regularly talk with stations whose signals are at the –20 or –25 level. It is as if the noise is moving around and the software simply copies the letters from it. Magic. Multiplied.

3) If English is not your first language, or not one of your languages at all, this is an ideal mode. It is better than PSK, RTTY, and certainly better than SSB. It is the same as a brief contest contact in CW, in which the exchange is language-independent. With JT9, the QSO components are already established. Any language can communicate with any other language because the software arranges the QSO. Translating the explanation of JT9 into any language can cover the setup and operation of the WSJT-X software and you are on the air with JT9. K1JT has given permission to translate the WSJT-X User's Guide into any language as long as he is sent a copy of the translation so he can add it to the website.

4) What if you are a college student with a shiny new license, a limited ham radio budget, and questionable antenna possibilities? Or what if you just love seeing what you can do with low power and temporary antennas? With JT9, you can call CQ with 1 or 2 or 5 watts and get responses! You can have great success even over thousands of miles. This mode is perfect when you have a

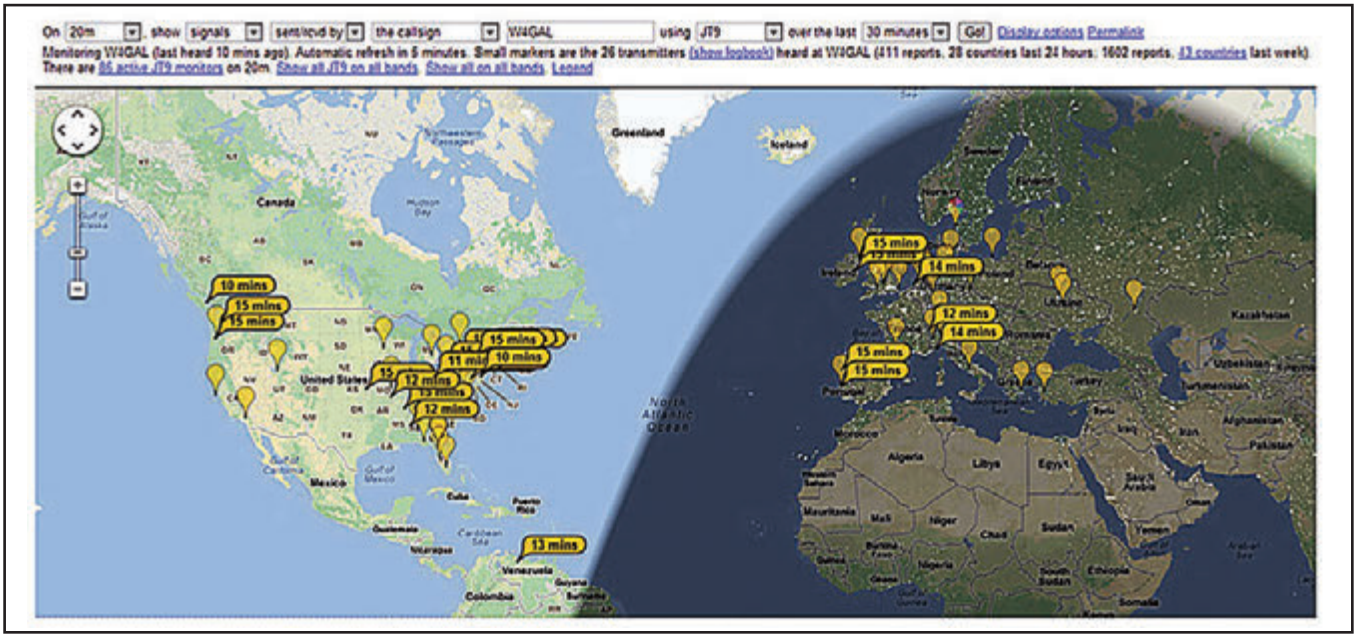

Fig. 1. Screen shot of stations hearing the author's 1-watt JT-9 signal from Florida, as displayed on the PSKREPORTER website.

little-pistol station. Photo B shows Shirl Regis, W9OMG, operating JT9 QRP with great results from her home in North Florida using an ICOM IC-718 cranked down to 5 watts and a temporary vertical antenna. Even if you have a big-gun station, see what you can do with 1 watt. Put the "wow" factor back into ham radio.

5) There is a powerful website available to us which displays signal reception reports from locations worldwide for a variety of modes. JT9 is one of the modes, and PSKREPORTER[1] is the site. After transmitting, you can look at PSKREPORTER and see which of the volunteer reporting stations received your transmission. I am having great success running somewhere between 1 and 5 watts, and I frequently look to see which stations, in which other continents, have also copied my signal.

Here is an example: I was using my TS-590 on a JT9 QSO with 1 watt power output through about 70 feet of RG8X to my vertical antenna in North Florida. I waited a few minutes after the QSO to do a "PrintScreen" because it takes a little while for the reporting stations to populate the PSKREPORTER map. Where was my transmission heard? Look at fig. 1. Holy smoke! My 1-watt

www.cq-amateur-radio.com

signal was heard across North America and into South America and Europe at that time of day.

How a QSO Works

Fig. 2 illustrates a JT9 QRP QSO with Jean Raynaud, F8RZ, in France. To explain the lines on the Band Activity screen, Jean called CQ (CQs appear in green). He was answered by RK1NA in Russia. At the end of their QSO, Jean called CQ again and I answered by double-clicking on his CQ. That started our QSO in the Rx Frequency window. He replied to me (his reply appeared in red) and said I was a –07 in signal strength. I replied that he was a –10. The software supplies the data automatically. He asked for a repeat and I sent it again. He acknowledged it and said 73. I said I was running 5 watts with a vertical, and thank you 73. End of QSO.

Here's the rub: It takes 50 seconds to send each 13-character message—which, I might add, gives you enough time to enjoy your cup of coffee and to look at QRZ.com and see who you are talking with during the QSO.

Equipment

You need a transceiver running 20 watts or less power, a computer, a sound-card interface to connect the two, and some free software. The standard SignaLink and Rigblaster types of modems work fine, and many rigs like my Kenwood TS-590 have a built-in sound card which does the job. I like using an outboard unit instead because it has a knob on it so I can adjust the drive level in real-time and choose the output power as I go. I can set the TS-590 at its minimum 5-watt level and dial-down the drive to where the output showing on my MFJ antenna tuner is 1 watt.

You will also need to sync your computer clock with a timing program such as Meinberg NTP.[2] If you can't get your computer to within one-half second of an international time standard, the WSJT-X program may not decode anyone. You can find what you need to know with instructions and downloadable software on the WSJT-X website.[3] Read the User's Guide first; don't wait until you have problems! And you can get help from hams experienced with JT9 if needed.[4]

Success, PLUS

When operating from your apartment with 5 watts and a stealth antenna hanging out the window, you can have amazing success on JT9. And it's true pretty much worldwide. You can call CQ and you will get responses. On JT9, if you're running 1 watt and not getting answered by the station you are calling but you can see on PSKREPORTER that you were "heard" by 10 others, it's not discouraging at all. You will also get a lot of eQSLs if you enjoy that. There seems to be a direct correlation between using a computer in your ham operating mode and the percentage of contacts confirming the QSO. It's true of PSK, JT65, and certainly of JT9.

For me, JT9 is the perfect QRP mode. Try it out!

Thanks, Joe, K1JT

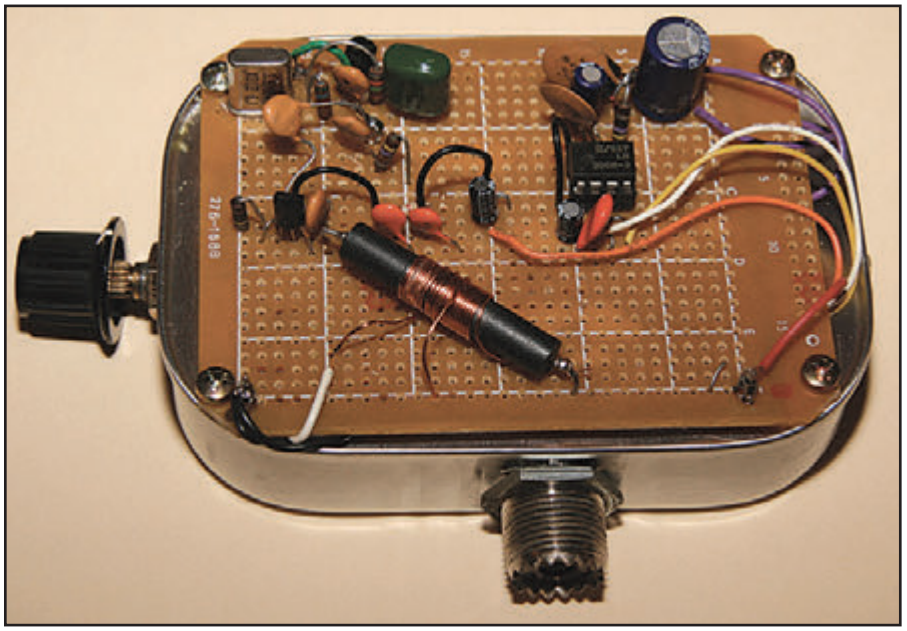
QRP is all about low-power transmitting, often translating into physically small transmitters. Here's a project to build a small receiver—that fits in a sardine tin!—to accompany your tiny transmitter.

Build the 80m Sardine-Ceiver

BY ERIK WESTGARD,* NY9D



NY9D's "Sardine-Ceiver" is a fun-to-build companion receiver for W1FB's classic "Sardine Sender" QRP transmitter.

The concept of an amateur radio "Junk Box" construction project has taken a beating over the last quarter century. Whenever I see one of these, they usually specify one or more components I don't have, even in my extensive inventory. This is after decades of diligent scrap collecting, and a fair bit of deliberate ordering ahead of normal radio construction parts (such as T50-2 toroids) from mail-order suppliers.

The late Doug DeMaw, W1FB, recognized this in his later construction books and articles. He started seeing the supply of variable capacitors and other staples of radio projects disappear from store shelves.Soon after converting the 1978 era all-RadioShack W1FB Sardine Sender to use the newer 100-µh RF chokes, I thought a companionreceiver with only common, locally available parts would be a good project.

I delved into Doug's books and my article archives. The design goals were to have no toroids and to avoid the NE602/612, as it was rare in local stores and in common scrap. I was eyeing a couple of non-working VCRs, which are loaded with RF chokes and other useful components.

I wanted to make the receiver tunable, so I tried out some VVC/varactor-diode tuned VFOs. This effort was very frustrating, and it would not use variable capacitors for tuning or even adjustments. This ruled out most of the available QRP receiver circuit diagrams. The final requirement was to not use dual gate MosFET devices, which were also getting scarce in the stores and scrap piles.

I gave a talk at the Dayton QRPCI meeting called Four Days in May in 2002, and met George Dobbs, G3RJV, a fellow W1FB fan and leading light of the G-QRP Club. He was selling a tiny book called *Minimalist Radio*, which featured a simple mixer based on the MPF102/NTE451 device and had no variable capacitors. The front end was for 40 or 20 meters, and so this book was not an immediate solution, but joined my growing pile of reference articles.

After a few long weekends and several dead-end prototypes, I was not getting far. I even built a Pixie, which was the right idea and the right band. However, the Pixie was prone to BCI (broadcast interference) from a powerful nearby AM station. The events of 9/11 sent me off in the direction of public service and packet radio, and later D-Star, and away from QRP for a while.

Re-awakening a Latent Interest

Recently, I was cleaning out my office and found a W1FB article on an 80-meter-band converter that had a single-ended mixer and an 80-meter front end. The light went on in my head after seven years and I raced for the shop.

The little receiver in George's book was fully modular; you could build it in sections. Therefore, I started with his mixer, and added in a VFO—really a basic crystal oscillator from the selection in Doug's book, *QRP Notebook*. The Colpitts oscillator used a common 2N2222A and a TV colorburst crystal and had no variable capacitors or trans-

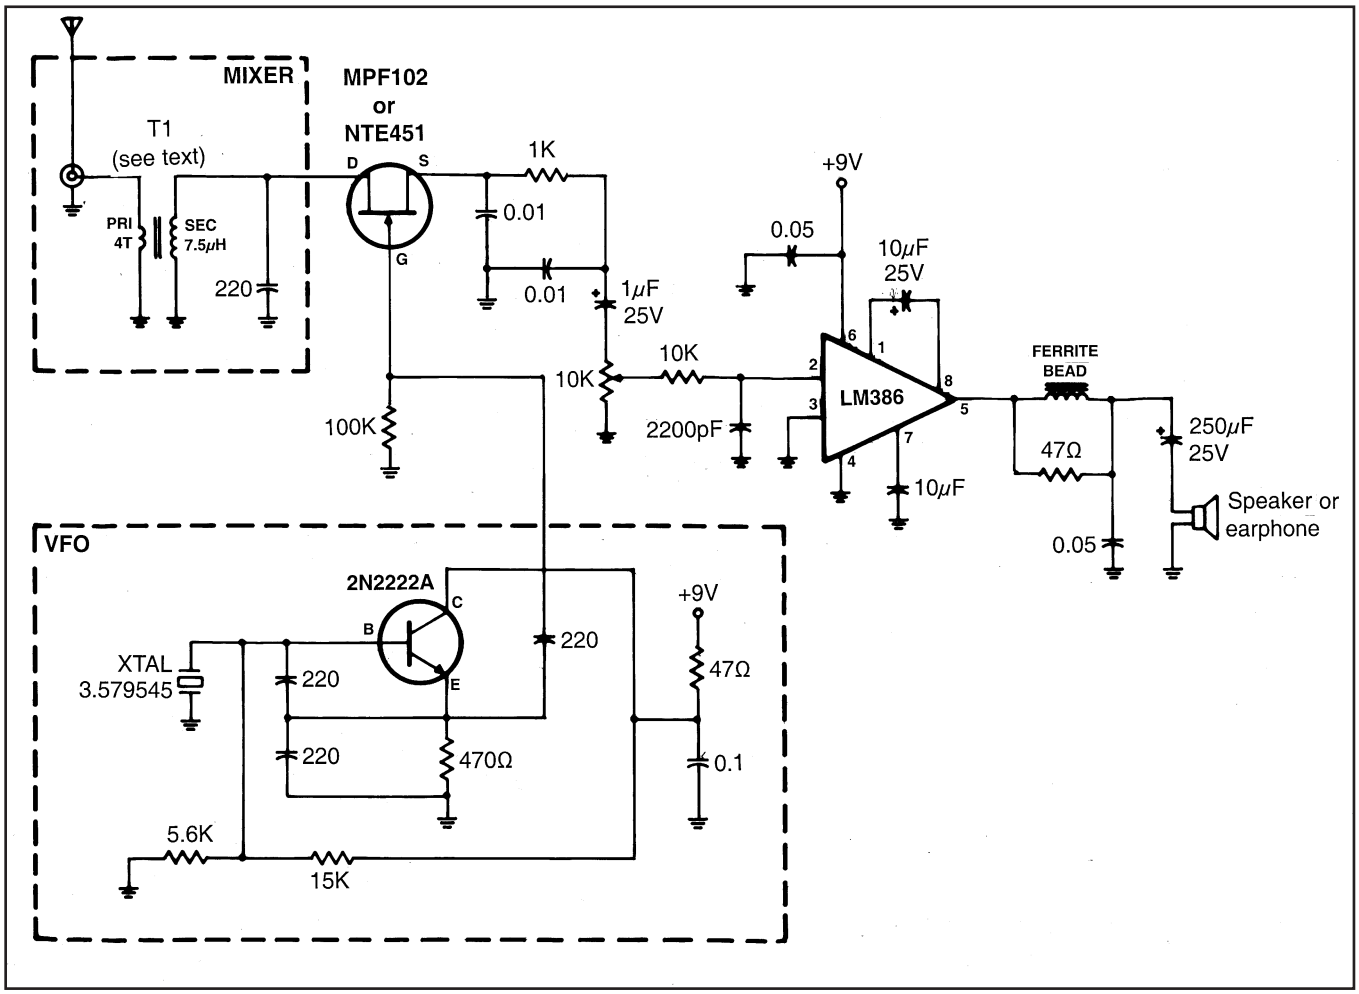

Fig. 1.The SardineCeiver merges a mixer circuit by G3RJV with a W1FB VFO design and a National Semiconductor audio circuit for the LM386. The ferrite bead comes from an old VCR.For T1. Remove all but 19 turns from a RadioShack 100 μH RF choke (273-102), leaving a 7.5 μH secondary; then used some of the removed wire to wind a 4-turn primary over the secondary winding.

formers. The math for the capacitors didn't work out, so taking a tip from Doug, I built a prototype and tried some different caps; 220 pF did the job and it started oscillating. For an audio amp, there was one for an AM radio amp in the National Semiconductor application notes for the LM386. Having had my fill of AM BC RFI, this might be OK.

And for the tuned front end there was Doug's converter article, 7.5 μH as a secondary on a T50-2 toroid and about 220 pF in parallel. Doug had the front end go to the gate on the MPF-102; for the G3RJV design it went to the drain. I said to myself, "Cross your fingers and solder to the drain."

I hooked it up to my RF signal generator and sent in a signal. Yes, it was a receiver, but at the millivolt level not the microvolt level. This was better than the last time, but not good enough. After several frustrating sessions of trying to change values and add stages, one night I took off the signal generator and

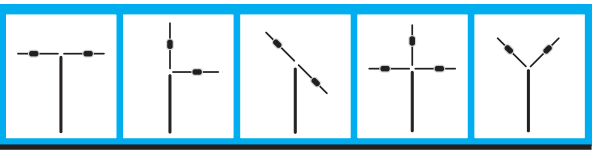
BUDDIPOLE

Please call or write for free brochure!



WHAT IS THE BUDDIPOLE?

The Buddipole™ Portable Dipole fits in your travel bag and assembles in minutes. The Buddipole is more than an antenna, it's a versatile system for launching your signal. Optimized for transmit power and proven for DX work, the Buddipole is the secret weapon used by HF portable operators all over the world.

BUDDIPOLE FEATURES

- Multi-band design works 9 bands (40 meters thru 2 meters) with one set of adjustable coils!
- Rated from QRP to 250 watts PEP
- Modular Design – create dozens of different antennas with interchangeable parts
- Rotatable/Directional
- Lightweight, rugged components
- Rotating Arm Kit allows users to instantly change antenna configurations
- Used by Emergency Services Groups throughout the world

hooked up a tuned antenna—my G5RV. To my astonishment, clear CW signals from all over the USA were heard. I sat transfixed for a while. George makes the comment (disagreeing with Doug, who does not like single-ended mixers) that it "…works oddly well," which I think fits.

I made up a RadioShack 273-102 100 µH RF choke to match the 7.5 µH secondary (remove all but 19 turns for the secondary and use the leftover wire to make a primary winding over the secondary with four turns). I swapped out the T50-2 toroid transformer for the RadioShack homemade version and it worked the same. I next got out the prototype Sardine Sender transmitter and started calling CQ. After a few hours of that one afternoon in poor conditions, I sent an e-mail to QRP builder AAØZZ, who lived nearby, and asked him to get on the air. Soon I worked him, rusty CW and all. Then it was off to the store for a sardine can.

Most of the parts are available at RadioShack, where the components have moved off the pegboard into drawers in the back. Ceramic capacitors are used for the 220-pF applications. RadioShack has an assortment that might include those, or you can use 100-pF models in parallel. RadioShack used to sell the crystal, but for that now, an old VCR or TV will usually have one. If you don't have one to scrap out (the older the better for fewer surface-mount parts), ask around or check at thrift stores.

Troubleshooting the project consists of building it in stages; maybe start with audio. If it works, you should hear a hiss, and you can tap the input and have it click. The RF bead came out of an old VCR and can be omitted. I think it helps a bit with RF interference. The oscillator should oscillate, and you should be able to hear it in a nearby receiver. The front end and mixer should hear signals (CW, SSB, and even shortwave broadcast stations) if you have it right. Use a good antenna. This little radio is not very sensitive but was nice and clear here. I used a 9V battery, as the LM386 is famous for not liking normal 12–13.6-VDC ham shack power. I got a little local 80-meter SSB interference during the big sweepstakes contest, but no BCI.

The MPF102 is getting harder to find, but NTE451s are still around at places such as Allied Radio, so the mixer design might need to adapt to other locally available semiconductors. I do think the idea of a VFO of some kind is a worthwhile upgrade, as it would be nice to be able to move around the band a little. Of course, too, you can try different circuit modules yourself—such as the audio amplifier—depending on your interests or the parts you have on hand. It is reasonably cheap these days ($20 for one I saw on eBay) to buy a meter to measure inductance, so if you are modifying the RadioShack RF choke (or winding your own toroids) you can check your work.

Need proof of how far a QRP signal can travel? Try K1JT's WSPR program and see where you're being heard; plus which bands are open to where in real time.

Build Your Own WSPR Beacon

BY YANNICK DEVOS,* XV4Y

The *Weak Signal Propagation Reporter*, WSPR, is a real-time propagation tool invented by Joe Taylor, K1JT. I, for instance, use it as a way to learn the propagation on a band and determine the best time to work a given DX path. Thanks to WSPR, I learned that there is an 80-meter path between the US and Vietnam even in summer, and I got confirmation that the best openings are right after sunrise in North America.

Using WSPR requires a low-power beacon transmitter (the subject of this article) and an Internet-linked computer to let you see where your signal is being heard. If you'd like more background information about WSPR, please refer to G4ILO's excellent article at <http://www.g4ilo.com/wspr. html> or to the presentation by the software's author, K1JT, at <http://www.physics.princeton.edu/pulsar/K1JT/wspr.html>.

Who is This Circuit For?

If you're a homebrewer ham with basic digital and RF skills, this WSPR beacon project (photo A and fig. 1) is for you. There is no need for laboratory measurement equipment such as an oscilloscope. Everything should run straight from the beginning. However, some care and patience may be required, because the parts used will not accept any overvoltage or polarity inversion.

Component parts for this project (see photo B) are readily available (see below) or you can build it from a kit with a PCB and all the parts included. The kit I recommend is the Ultimate 3 QRSS Beacon from Hans Summers, GØUPL <www.hanssummers.com>. *(QRSS refers to very slow speed CW, as often used on the VLF, or very low frequency, bands.—ed.)*

I used to sell what I called "semi-kits" for this circuit (photo C), but now Hans has carefully refined its design and his kit offers more value for the money. Some of our choices are different (for example, my source code is freely available and easily customizable), but you can make your own decision.

Design Choices

I first started to work on this project two years ago. KD1JV (father of the ATS/MTR transceivers) introduced me to the MSP430 family of micro-controllers and I quickly wrote a small WSPR keyer to use with my QRSS beacon (original beacon kit from Hans, GØUPL). The main advantage of the MSP430G2553, as it is provided with the LaunchPad board from Texas Instruments, is the ability to drive a 32.768-kHz crystal like you find in clocks. Then with a few lines of code you can have a fairly accurate *Real-Time Clock (RTC).*

Photo A. Screen of the author's WSPR beacon while transmitting a Weak Signal Propagation Reporter *signal.*

Why do we need an RTC for a beacon? Because WSPR is very time sensitive. In order to recover the data through the QRM, it uses a known time frame to guess the missing digital symbols from the other good ones. If you're off more than 2 seconds from the other stations, you will see that the successful decoding rate will drop significantly. Most WSPR users have the K1JT software running on a computer with the time set via the *Network Time Protocol* (http://www.ntp.org/). The first WSPR standalone beacon designs all used a GPS-controlled clock. Two years ago, dedicated GPS modules were expensive (and they still are somewhat), so that was a no-go for me.

The MSP430 Launchpad enables me to have a WSPR beacon running for up to three days with accurate timing. For longer durations, it was drifting too much from real time, but the only thing I had to do was manually set it to second zero of an even minute, using my smartphone's internal GPS with an Android application such as "Atomic Clock."

Parts Providers for the LaunchPad, Display and DDS Module

Well, for the MSP430 LaunchPad evaluation board, you should go straight to Texas Instruments (http://www.ti.com/tool/msp-exp430g2). It's available there for less than $10 with all the required parts and even more.

*e-mail: <xv4y@nature-mekong.com>

Table I. MSP430G2XX3 (TI Launchpad) Pinouts. See schematic, fig. 1, for additional connection information.

The DDS module, Nokia 5110-like display, and small parts (switches, cables) are readily available from Chinese sellers on eBay or many suppliers in the United States. My provider of choice is called "Chip_Partner" <http://www.ebay.com/sch/chip_partner/m.html>, but there are many. I also have had good experience with a website named IC Station <http://www.icstation.com/>. I have no relationship with either apart from the fact that they are my usual providers. Prices have decreased tremendously and should be around $5 for the DDS module and $3 for the LCD.

My own experience led me to buy the AD9850 modules with only two rows of pins and a big blue trimmer. I prefer the ones with a full-size canned oscillator (not the SMD version), as they usually have better frequency stability. An AD9850 with 125-MHz reference clock will allow you to generate signals between a few Hz and 30 MHz. (Pin 1 of each row is identified by a square.)

WSPR and QRSS are very demanding in terms of signal purity and frequency stability. I had only bad experiences with the AD9851 modules and the "three rows" modules. Even with the AD9850 two-rows modules, it is not unusual to have 10% of the parts that are a bit on the edge regarding specifications. It is not unwise to buy two of them, as they are cheap. Keep the best one for WSPR; the other one will be good as a VFO for a small receiver.

A last note about the LCD: It is not required in the WSPR beacon source code I am providing. However, given its price, I would not hesitate long, because without it you will lose a lot of flexibility.

Source Code for the Firmware

On my own website I made available three source codes for firmware running on this circuit. This programs must be compiled and uploaded to the LaunchPad's MSP430G2553 using

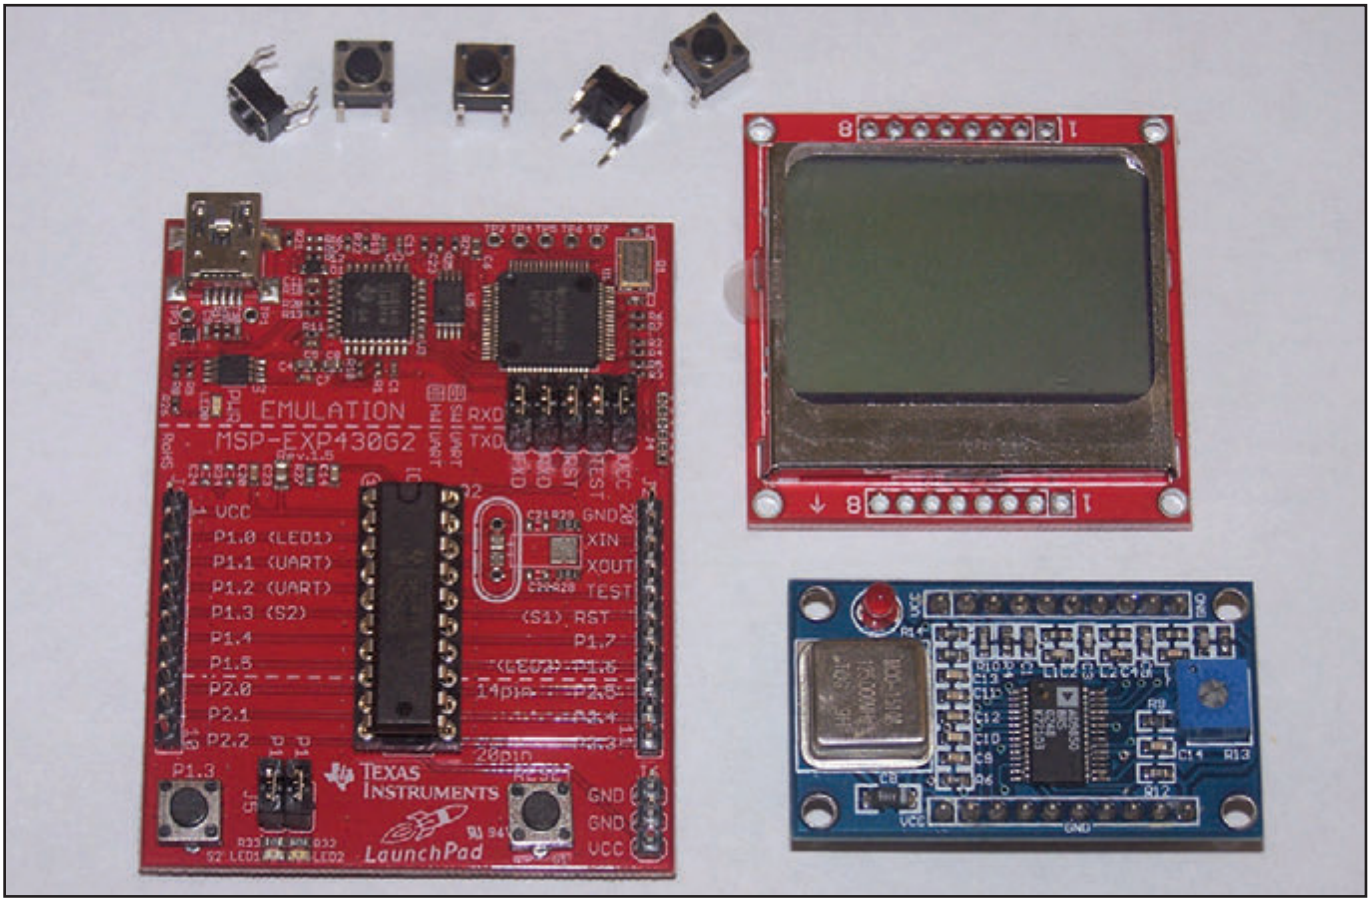

Photo B. Basic parts needed for the beacon include the Texas Instruments Launchpad (left), LCD display (upper right), AD9850 module (lower right), and several switches.

The Elecraft K-Line

A powerful performance you won't want to miss

Elecraft's world-class trio is now complete. It all started with the K3 transceiver, which tops the charts in nearly every receive category. Then we added an exciting visual dimension with the versatile P3, our fast, full-color panadapter. And now, we're proud to introduce the KPA500: a 500-watt solid-state amp that's so well-integrated you'll think it's reading your mind.

The KPA500 features 160-6 m coverage, instant RF-based band switching with any radio, alphanumeric status display, bright LED bar graphs, and a rugged, built-in linear supply. The amp's manual band switches can be used to change bands on the K3. The K3 can even select per-band amplifier drive levels automatically when the amp is placed into operate mode, so you'll rarely need to adjust power output.

The K3 already gives you the competitive edge, with its optional high-performance sub receiver, roofing filters as narrow as 200 Hz, new audio peaking filter (APF), and one of the cleanest SSB signals around. Adding the P3 and KPA500 will take you, and your station, to the next level.

the Energia IDE. All details are on this web page: <http://xv4y.radioclub.asia/cq-magazine-wspr-beacon/>.

With this circuit and compiling/uploading the firmware you can build:

- A full-featured WSPR beacon with runtime parameters to select the callsign, grid locator, band, frequency, and WSPR version (standard WSPR-2 or WSPR-15 for VLF).
- A QRSS beacon with menu selection for frequency, keying width, band cycling.
- A very simple DDS controller with VFO A/B and band selection to build a signal generator or a small transceiver local oscillator (LO).

In order to compile the given codes you will need to download and install them in the Energia libraries directory. Two are written by me (RTC Clock and AD9850 control) and one is a third-party library (Nokia-5110 display control). All are available on the previously indicated web page as well as the user's manual for the firmware explaining the settings and beacon behavior.

How to Interact with the Micro-controller

On my kits I used to install five push-buttons, four as up/down and right/left and one for validating. The WSPR firmware uses only three: up, down, and validate. You are free to only solder three buttons, but you may have to change the source code and will not be able to use the VFO software, which needs five buttons. For the price of two buttons and two 1k-Ω resistors, I recommend that you install all five buttons.

If you're using the same resistor values I am (10k and 1k), then the original source code should work. If you're using different values (or low-precision parts), you may need to adjust some numbers in the source code for mapping with the internal ADC measurements. In that case, the simple "AnalogInSerialOut" example code provided with Energia will give you the right values for each button-press.

There is also a PTT signal on Pin 2 of Port 2 of the MSP430. It is high when transmitting and low when idling. While idling, the DDS is put in "power saving" mode, turning off its output. If you run a class C or D/E amplifier, this will be enough to save power. If you want to do trickier things, feel free to use the PTT signal.

Which Voltage for DC Input?

Using a *Low Drop-Out* linear regulator such as the LVT1117-33, input voltage can be between 5V and 10V. If you want to power it from more than 10V (if you have a 12V rail from your PA), just add two or three 1N4007 diodes in series with the regulator input.

For simplicity, I only use one 3.3V Vcc rail for the MSP430G2553, the LCD screen, and the DDS module. The AD9850 is also happy at 5V and will even put out a little bit more RF power at this voltage. When using AD9851 modules (which I don't recommend), this is necessary because the 160-MHz clock may require them to be powered from 5V (even if the module's specifications states the opposite) in order to have reliable functioning.

You can add a separate 5V rail solely for powering the DDS, but take care not to mix both 5V and 3.3V rails because you can easily fry the MSP430 MCU.

At 3.3V, the circuit (LaunchPad + AD9850 + LCD) draws less than 500mA. If you run the AD9850 at 5V, it will draw more current.

Just as a comment, you can also power the circuit through the USB port of the LaunchPad. However, I don't recommend it except for testing and debugging. While using it "in pro-

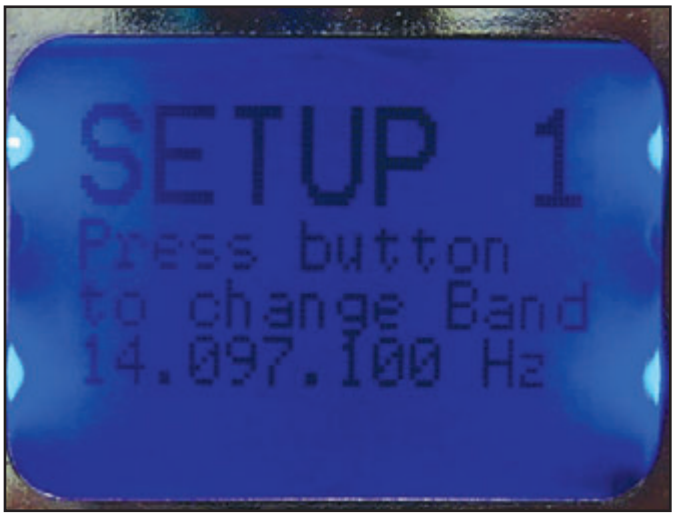

Photo D. Everything should work first time, every time. This is the setup screen you should see on initial power-up.

duction," I recommend that you open the five jumpers connecting the two parts of the LaunchPad and only power the LaunchPad from an outside source. Of course, never connect both power sources at the same time!

Building Advice

There are no special recommendations and everything should work from the first try (photo D). Sometimes, with some screens, when powering on the whole circuit, the LCD does not initialize itself well (maybe it is not ready while receiving the reset commands). If this happens, try to do a reset using the dedicated button on the LaunchPad board (putting the RESET signal to low).

Try to keep your connections short, but frankly speaking, I have been running "hairy" prototypes with long connections and everything still works well.

If you want to see pictures of how I actually built my own beacon, you can have a look at my blog. Most pages are in French, but an automatic translation is provided so you should understand what I'm talking about. Here is the latest article concerning this project: <http://xv4y.radioclub.asia/2013/06/23/montage-dun-kit-filtre-passe-bas-universal-de-kits-and-parts/>

Should You Use a Power Amplifier?

The DDS board output's spectral purity is rather good since it has a fairly high clock reference and 70-MHz low-pass filter. However, if you plan to use this kit for frequencies below 2 MHz or above 25 MHz with a high-gain amplifier, more filtering may be required.

As is, the DDS output power level is around 4 dBm. This is all right for a VFO or a signal generator, but a bit low for a beacon, even with WSPR. One watt is a good target level for such usage, as WSPR is considered at least 10 dB more "sensitive" than CW.

On HF, several class C power amplifier (PA) designs can provide output of about 5W for 10mW input. Kits and Parts (photo E) and the DL-QRP Group offer high-quality kits for this purpose. The latter is more expensive but may be used on higher frequencies. The ZOUT1 output of the DDS board has 50-ohm impedance, so you should be able to hook it directly to either of those PAs.

Using the comparator output (QOUT1) and adjusting the blue potentiometer to have a 50% duty-cycle, you can also feed the RF to a class E power amplifier as Hans, GØUPL, does on his Ultimate 2 and 3 QRSS beacon kits. You may grab its design or the one from Steve, KD1JV. They use digital parts such as the 74HC00 as driver and several Bs170s (or 2N7000s) in parallels for the final.

A Few Final Words

I hope you enjoyed reading this article and that you will have fun building your own project. All my source code is available under GNU GPL License for non-commercial use and may be modified to better fit your needs. Feel free to leave comments on my blog page dedicated to this article and I will try to answer your questions as soon as possible.

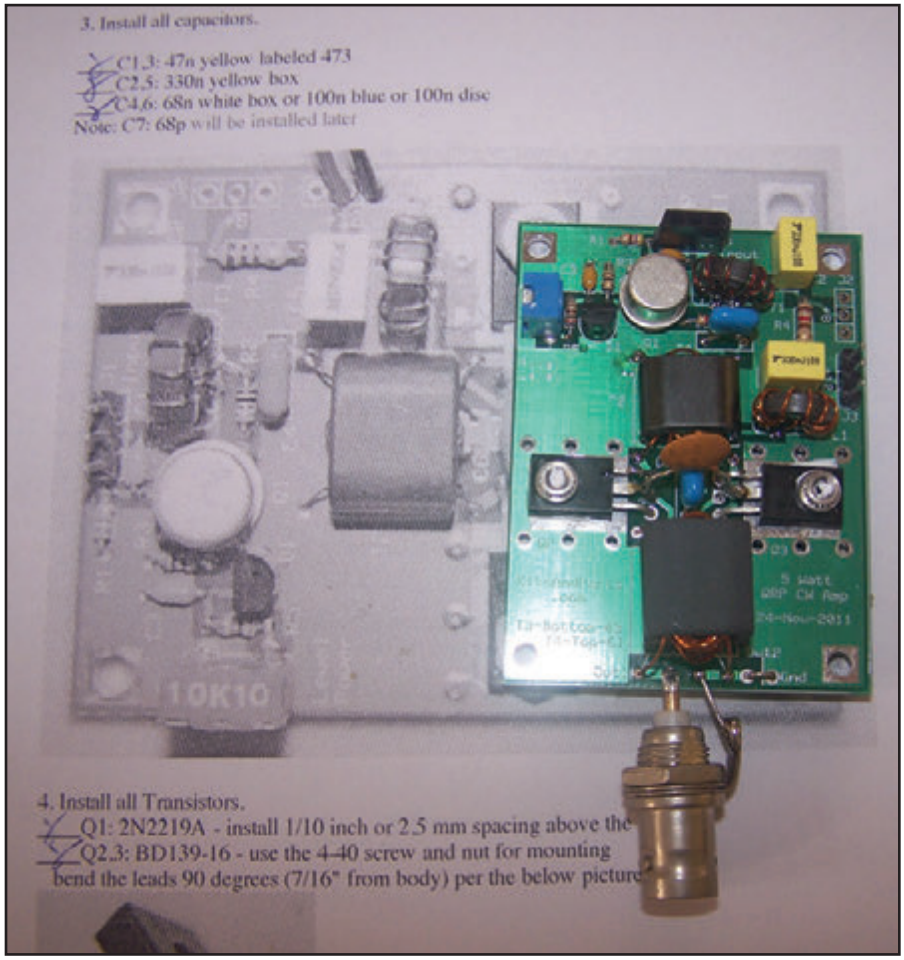

Photo E. Kits and Parts (www.kitsandparts.com) offers a class C power amplifier that may be used with the beacon transmitter. Similar amps are available from other sources as well.

Using a wireless digital network may not seem like traditional QRP, but transmitting with low power is at the core of how these networks operate. Here's a basic guide to setting up your own.

Setting Up a Mesh Network Node

BY J. GORDON BEATTIE, JR.,* W2TTT

You may have read about "mesh nodes" or "mesh networks" and wondered how these amateur radio nodes get configured to produce a functional network. Amateur radio mesh nodes based on the *Austin Broadband-Hamnet (HSMM-MESH) Group's* wonderful software take care of the identification requirements while also creating functional networks that can be used for both routine and emergency communications.[1] With this software, readily available Linksys WRT-54G/GS/GL routers (photo A) can be transformed into mesh network nodes that provide fast and robust self-organizing networks through which we can pass text, data files, video, and even voice traffic.

There is an inherent simplicity to the Linksys implementation that is quite attractive to the new user of this technology and it is strongly recommended as an entry-level system. In this article, we will be discussing the setup and configuration of the Linksys-based HSMM-MESH/Broadband-Hamnet nodes.

Getting Started

You will need to obtain a Linksys router, and that requires some care to get a model and version that are compatible with the mesh software. The compatible models use the Linux operating system. You can find the model and version information on the bottom of the router in the upper left corner of the label right under the Linksys logo as shown in photo B. See Table I for a listing of compatible models and required software. If you find a router on the Internet, it s likely to be pre-loaded with an aftermarket software build called "DD-WRT" which provides some additional conventional router functions. If you find such a unit at an attractive price, don't be worried about compatibility as long as the version is listed in Table I. Of course, the best unit is one that has the correct version, powers up, and is *free*, so check garage sales and local thrift stores. For reference, the WRT-54GS versions 1 through 3 are the best, because they provide the most memory for embedded applications to be resident on the mesh node.

Photo A. Three different models of Linksys routers (from top, WRT54GL, WRT54GS and WRT54G) that are ideal for use as nodes in Broadband/Hamnet (HSMM-MESH) networks.

*e-mail: <W2TTT@att.net>

Model	Version/Notes	Software Version
WRT-54	V1-4 (V1 is 5V only)	bbhn-1.0.0-wrt54g
WRT-54GS	V1-3 Most desirable has large memory capacity	bbhn-1.0.0-wrt54gs
WRT-54GS	V4	bbhn-1.0.0-wrt54gs_v4
WRT-54GL	V1.0–1.1	bbhn-1.0.0-wrt54g

Table I. Mesh network-compatible Linksys WRT-54/WRT54GS/WRT-54GL models.

Once you have your router, plug it in and make sure that it cycles up in a few seconds. If successful, the "Power" and "WLAN" LEDs will be lit. Next, connect your computer's Ethernet port to any one of the router's LAN ports, labeled 1–4, then open up a web browser and enter the IP address <http://192.168.1.1> to log on to the router's administrative console. If the router is in its default mode and is running Linksys software, then you will need to enter nothing in the user name field and "admin" in the password field. If you are repurposing a router with DD-WRT, then you will use the logon of "root" and "admin" as your password. One of these should let you into the router's administrative console.

Troubleshooting Router Access

If you have trouble accessing the router's logon screen, then you may need to get a new IP address from this router. For Windows® PCs, go to a system command prompt[2] and type "IPCONFIG/RELEASE <cr>" and then "IPCONFIG/RENEW<cr>" (see fig. 1). You should then be able to access the router and log on. Apple and Linux-based systems have similar commands.

If you have trouble with the logon and password because you either don't know them or forgot them, then power on the router while holding the reset button down with a pen for about 30 seconds. This will clear the whole configuration and should restore the router to default settings.

Obtaining and Loading the MESH Software

There are several different files to use with your Linksys router depending on its model and version. You will find the correct file name for your hardware in Table I. Download the needed file from either the Broadband-Hamnet web site <http://www.hsmm-mesh.org/software-download.html> or from the file section of the "ComTechGroup" Yahoo Group <http://groups.yahoo.com/group/ComTechGroup/>, which you can easily join by simply requesting access.

Once the file is saved on your computer and you have logged into the router, select the "Administration" section tab and then select the "Upgrade" button. You will be prompted for a filename. Browse over to the correct folder and select the file. *At NO TIME during this phase of the process should you unplug the router from the PC.* Once completed, you will note that the router reboots and is now an unconfigured mesh node. Your router will take a bit longer to boot the mesh software than it did the default Linksys or other router software. The "Power" LED will begin to flash, then the "DMZ" LED will come on. Once the "DMZ" LED goes off and the "WLAN" LED starts to flash, you have successfully loaded and rebooted your mesh node! You will see that the header of the page has your call sign and identifier on top, along with a page of statistical elements. *Congratulate yourself!*

Basic ASIC MESH Node Configuration

You're making progress, but you have more to do. First, you will probably need to repeat the process of releasing the old IP address and obtaining a new one as you did when initially accessing the console. (These addresses are generated by the router itself. See fig. 1.) Once you have the new IP address, then enter "http://localnode:8080 <cr>" to see the main mesh node console as shown in fig. 2. Click on the "Setup" button and enter a logon of "root" and "mesh" as your password.

You will then be presented with a basic configuration screen as shown in fig. 3. You will need to enter a new value for the "Node Name." It should include your call sign with an extension that makes the node unique with respect to its ID. Some folks use functional extensions with serial numbers, while other put in locations. There are no hard and

Photo B. The bottom of a Linksys router will show you its model number and version information.

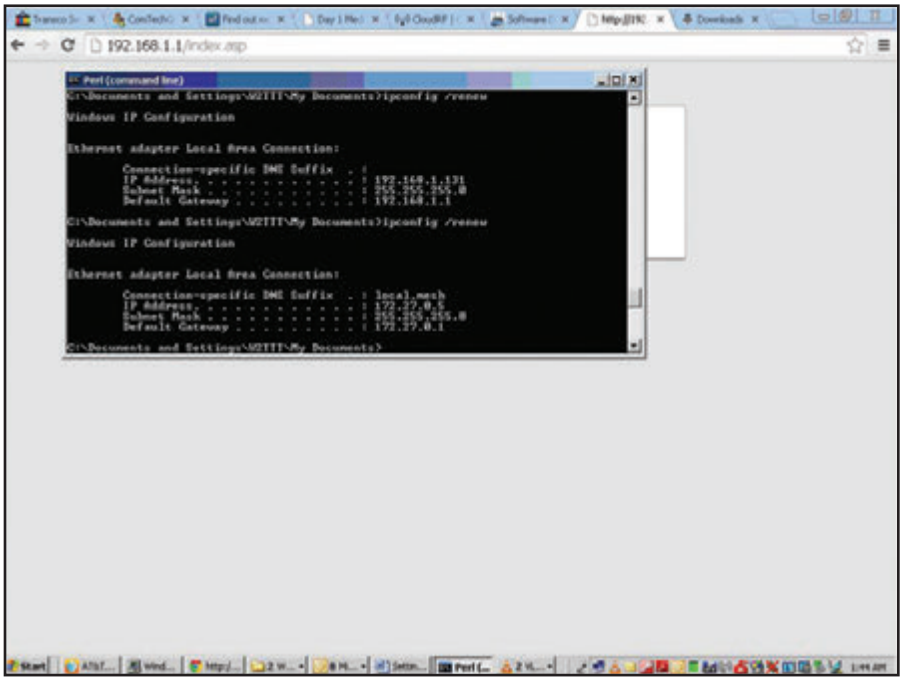

Fig. 1. Windows IPCONFIG example. Note the connection information of "local.mesh" in the lower part of the screen.

Reflections III

by Walt Maxwell, W2DU

All the info in Reflections I and II and more! This completely revised and updated, 424-page 3rd edition is a must-have!

8.5 X 11 Paperback $39.95
***New!* CD Version $29.95**
Buy both for only $59.95

W6SAI HF Antenna Handbook

by Bill Orr, W6SAI

W6SAI was known for his easy-to-understand writing style. In keeping with this tradition, this book is a thoroughly readable text for any antenna enthusiast, jam-packed with dozens of inexpensive, practical antenna projects that work!

8.5 X 11 Paperback $19.95
***New!* CD Version $14.95**
Buy both for only $29.95

Understanding, Building & Using Baluns & Ununs

by Jerry Sevick, W2FMI

The successor to the popular and authoritative Baluns and Ununs. Great deal of new tutorial material, and designs not in previous book, with crystal clear explanations of how and why they work.

8.5 X 11 Paperback $19.95
***New!* CD Version $14.95**
Buy both for only $29.95

Shipping & Handling: USA - $7 for 1st book, $3.50 for 2nd, $2 for each additional. **CN/MX** - $15 for 1st, $7 for 2nd, $3.50 for each additional. **All Other Countries** - $25 for 1st, $10 for 2nd, $5 for each additional.

CQ Communications Inc.

516-681-2922; Fax 516-681-2926
http://store.cq-amateur-radio.com

fast rules, but make sure that your call sign is at the beginning. You will also need to enter a new node password in two places. Make sure that you remember what you entered. You might even want to put a label on the bottom of the node with that password as long as you can maintain physical security, but in any case, *write it down—somewhere*!

Finally, it is strongly recommended that you move the node off of channel 1, 6, or 11, as they are the most popular ones in use for normal WiFi operations. We usually pick channel 3, but your local RF ecosystem may drive other choices. (*Note:* WiFi channels 1–6 are shared with the 2.3-GHz amateur band, so any planned activities under FCC Part 97

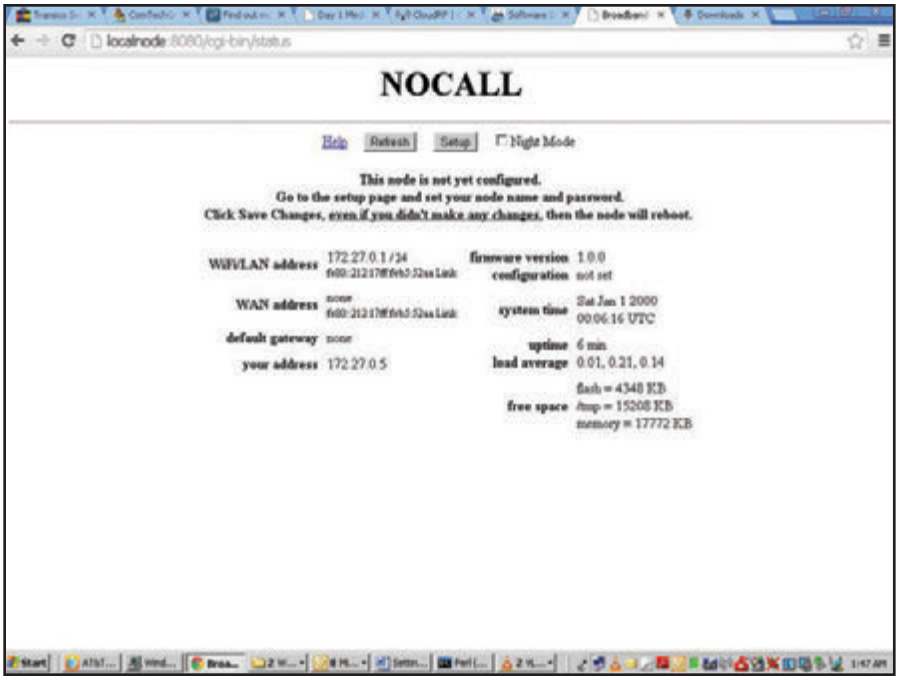

Fig. 2. This is the screen you will see after loading the mesh software but before configuring the node. You now need to do setup.

Fig. 3. The configuration screen will guide you through the steps needed for correct setup.

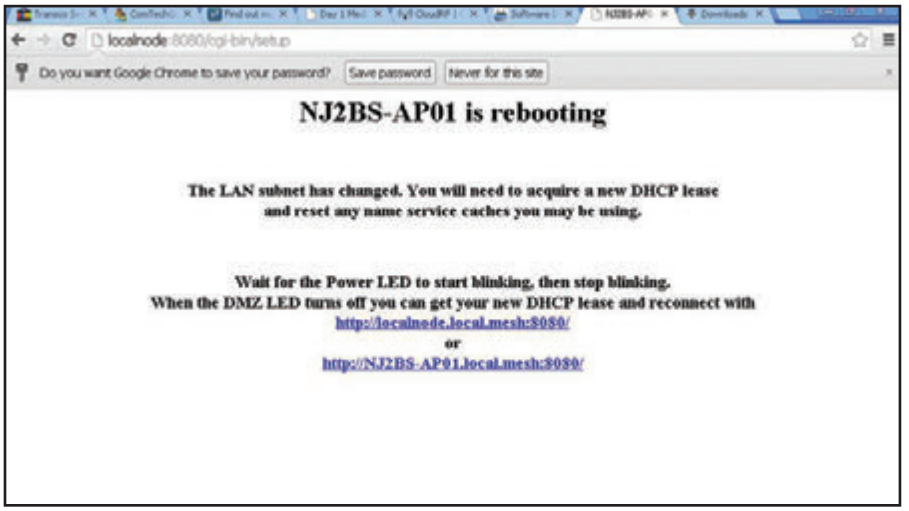

Fig. 4. Once you've entered all the necessary information, you'll get a screen that looks like this while the router is configuring and rebooting itself.

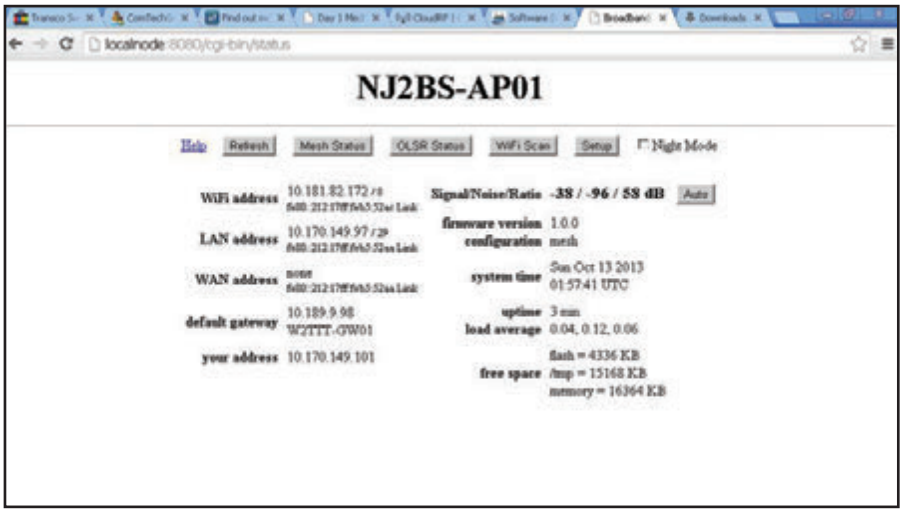

Fig. 5. Voila! Your mesh node is configured and ready to start communicating!

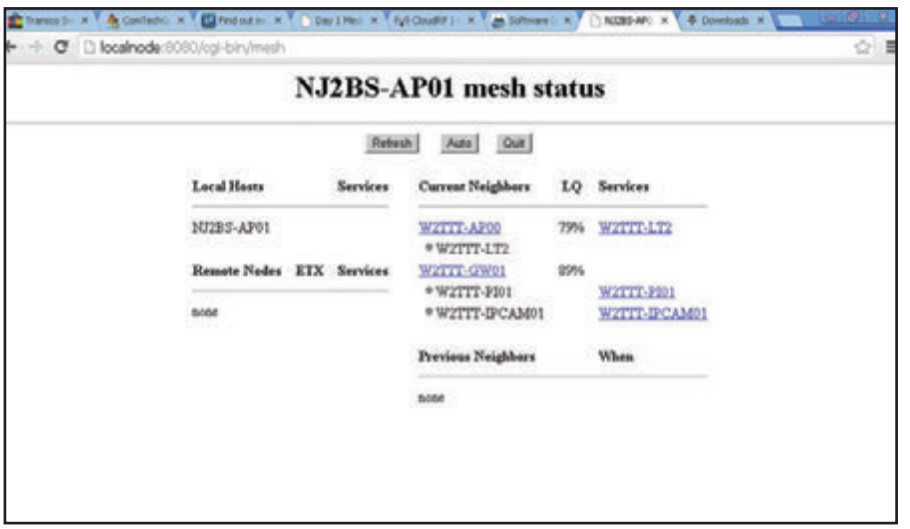

Fig. 6. The mesh network status screen shows you what other nodes are accessible to you as well as what features, or services, they offer.

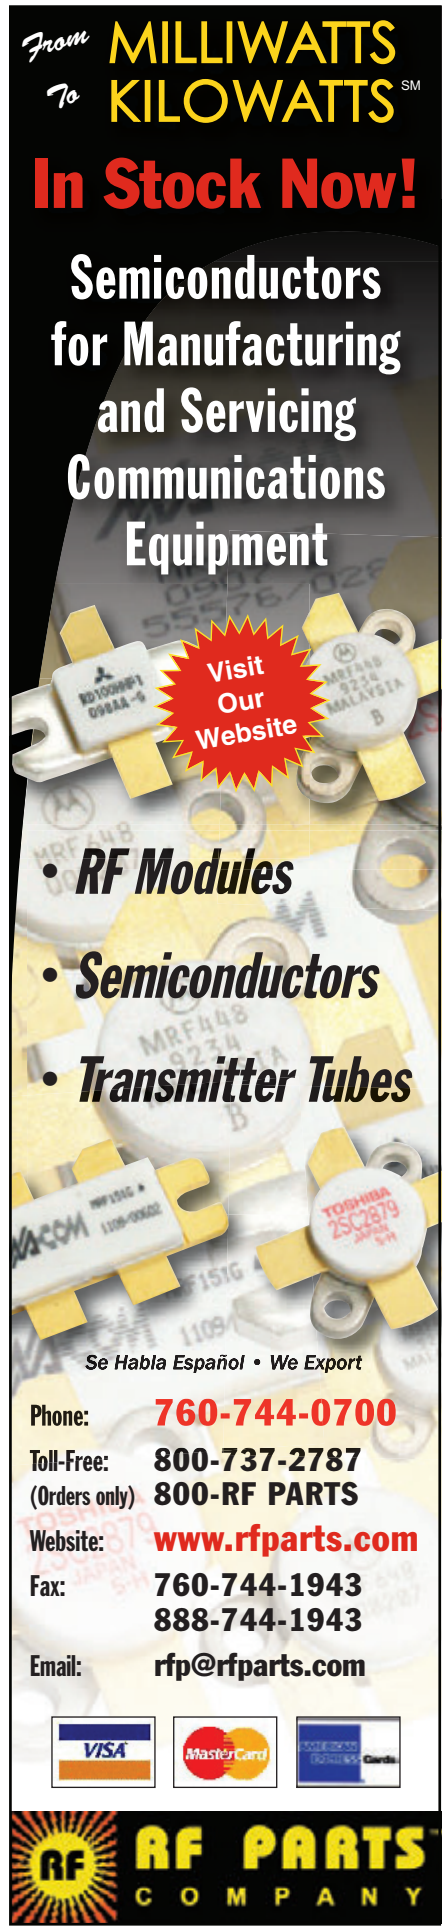

rules—which allow more power and antenna flexibility than Part 15 rules—must be conducted on one of these channels.)

One interesting thing to note is that if two mesh nodes are on different channels, they will search out other nodes on other channels, but at a cost in network performance. Once it is all entered, press the "Save Changes" button and the node will save your entries and reboot. During that reboot period you will see a screen as shown in fig. 4. Once it comes up as described previously, you will need to once again ensure that the computer gets a new IP address. Once that is done, enter "http://localnode:8080 <cr>" in your web browser, and you will be presented with a screen as shown in fig. 5. You now have a functional configured mesh node that should be ready to communicate. *Congratulate yourself again!*

Fig. 7. The Foscam IP camera lets the user select different modes based on which one works best on your browser. The camera is accessed and configured over the mesh network.

Fig. 8. Example of what you might see from the IP camera once you've selected a mode on which to view its photos.

Is There Anybody Out There?

OK, I borrowed the title line from Pink Floyd, but there really is a need to put up more than one node and find out if they can communicate with each other. In order to see neighboring nodes, select the "Mesh Status" button. If you have two configured nodes or have a nearby node, you will see something like what's shown in fig. 6.

As you can see, there are two neighboring mesh nodes and each has some defined "Services." You can connect to these services if they are defined and are using a compatible device. For example, W2TTT-LT2 is a Telnet server that allows for keyboard-to-keyboard connections, while W2TTT-PI01 is a Raspberry Pi computer running an Internet Relay Chat (IRC) server. The W2TTT-IPCAM01 is an IP camera. Connecting to this Foscam brand camera is as easy as clicking on the camera link from your web browser and following the camera server connection sequence (fig. 7). Along the way you will be prompted for a camera logon and password, and then you will be provided with a choice of camera server modes. Try each one with your browser to determine which option will give you success (fig. 8). ActiveX Mode provides full recording and snapshot capabilities which are not shown here as that plug-in was not installed into the Chrome browser that was used for the screen shots in figs. 7 and 8.

Just Do It!

We all have become interested in a topic that we've read about, gotten really fired up, and then came the practical reality of making it happen. You know the type of issues that come up…"I'm distracted," "I don't know how to find or load the new software," "What happens if I do it wrong?" etc. This article is an attempt to help you conquer those issues, and *get on the air*! I hope that you found it helpful and interesting.

Notes

1. See Beattie, "HSMM-MESH Networking in EmComm Applications," *CQ* October 2013, p. 26

2. To access the system command prompt in Windows, click on the "Start" or Windows logo button, then type "CMD" in the search bar and click on "CMD.EXE" when it comes up.

AMERITRON 600 Watt *no tune* FET Amp

Four rugged MRF-150 FETs at 50 Volts give high efficiency . . . No deterioration with use

ALS-600 **$1599** Suggested Retail

Ameritron ALS-600 *Solid State FET* compact desktop station amplifier is only 4 dB below 1500 Watts -- less than an S-unit!

There are no tubes, no tube heat, no tuning, no worry rugged -- just turn on, select band and operate. 600 Watts PEP/500W CW -- lets you talk to anyone you can hear!

Covers 1.5-22 MHz, (10/12 Meters with $29.95 kit, requires FCC license), instant bandswitching, SWR/thermal protected, extremely quiet, lighted peak reading Cross-Needle SWR/Wattmeter, front panel ALC control, operate/standby switch. 12.5 lbs., 9½Wx7⅛Hx12D in.

Includes ALS-600PS transformer AC power supply for 120/220 VAC, inrush current protected. 32 lbs., 9½Wx6Hx12D inches.

ALS-600 Amp with Switching Power Supply

***New!* ALS-600S, $1699.** ALS-600 amplifier with 10 lb. ALS-600SPS switching power supply combo.

Switching Power Supply

ALS-600SPS **$699** suggested retail

Works with all ALS-600 amplifiers. Extremely lightweight, just 10 lbs. Superb regulation, very low radiated noise. 9Wx6Hx14½D in.

From QST Magazine, March, 2005

". . . the ampifier faulted only when it was supposed to. It protected itself from our boneheaded, sleep-deprived band changing manuevers . . . "

"I found myself not worrying about damaging this amplifier. It seems quite capable of looking out for itself. . . . Kudos to Ameritron."

"I couldn't hear any noise at all from the SPS (*switching power supply*) on the vertical or quad…"

"I came to greatly appreciate the size, weight, reliability and simplicity of this amplifier."

"The ALS-600S makes it possible to pack a transceiver and a 600 Watt amplifier, that together weigh less than 30 pounds."

AMERITRON *mobile* 500 Watt *no tune* Solid State Amp

Instant bandswitching, no tuning, no warm-up, SWR protected, 1.5-22 MHz, quiet, compact

ALS-500M **$949** Suggested Retail

Ameritron's ALS-500M solid state *mobile* amp gives you 500 Watts PEP SSB or 400 Watts CW output! Just turn on and operate -- no warm-up, no tuning, instant bandswitching. Fits in very small spaces.

New ALS-500RC, $49 *Remote Head* lets you mount ALS-500M amplifier *anywhere* and gives you full control. Select desired band, turn On/Off and monitor current draw on its DC Current Meter. Has power, transmit and overload LEDs. RJ-45 cables plug into Amplifier/Remote Head.

Covers 1.5-22 MHz, (10/12 Meters with $29.95 kit, requires FCC license).

Virtually indestructible! *Load Fault Protection* eliminates amplifier damage due to operator error, antenna hitting tree branches, 18-wheeler passing by. *Thermal Overload Protection* disables/bypasses amp if temperature is excessively high. Auto resets.

Typically 60-70 watts in gives full output. ON/OFF switch bypasses amplifier for "barefoot" operation. Extremely quiet fan comes on as needed. Excellent harmonic suppression, push-pull output, DC current meter. 13.8 VDC/80 Amps. 3½x9x15 in. 7 lbs.

ALS-500M, $949, 500 Watt mobile amp.
ALS-500MR, $979, ALS-500M/Remote Head
ALS-500RC, $49, Remote head for ALS-500M (for serial # above 13049).
ARF-500K, $179.95, Remote kit for ALS-500M serial # lower than 13049. Includes AL-500RC Remote Head, filter/relay board for ALS-500M, cables, hardware, instructions.

Free online manuals! Ameritron brings you the finest high power accessories!

ARB-704 amp-to-rig interface. . . $59.95

Protects rig from damage by keying line transients and makes hook-up to your rig easy!

RCS-4 Remote Coax Switch . . . $159.95

Use 1 coax for **4** antennas. No control cable needed. SWR <1.25, 1.5 - 60 MHz. Useable to 100 MHz.

RCS-8V Remote Coax Switch. . . $169.95

Replace **5** coax with 1! 1.2 SWR at 250 MHz. Useable to 450 MHz.<.1 dB loss, 1kW@ 150MHz.

RCS-10 Remote Coax Switch. . . $179.95

Replace **8** coax with 1! SWR<1.3 to 60 MHz.**RCS-10L, $219.95** with lightning arrestors.

New! RCS-12C Fully Automatic Remote Coax Switch Controller. . . $239.95

Band data from transceiver auto selects antennas. Antenna memories. No hotswitching. Rig-to-amp interface. For 3/4 BCD, 1 of 8 relay boxes. **RCS-12, $309.95**, auto controller with 8 coax relay box, to 60 MHz. **RCS-12L, $349.95**, with lightning arrestors.

AWM-30 Precision SWR Wattmeter..$149.95

Active circuit gives *true* peak/average readings on lighted cross-needle meter.3000/ 300 Watt ranges, Remote sensor.

AWM-35 Flat Mobile SWR Wattmeter . . $159.95

1⅝ in. thin on dashboard. Remote sensor, 25' cable. True *peak*, Cross-Needle,1.5 kW, 1.8-30 MHz. *High-SWR* LED.

ATP-100 Tuning Pulser . . . $69.95

Safely tune up for full power, best linearity. Prevents overheating, tube damage, power supply stress, component failure.

ADL-1500 Dummy Load with oil . . . $74.95

Oil-cooled. 50 Ohms. 1500 Watts/5 minutes. SWR< 1.2 to 30 MHz. Low SWR to 400 MHz.

ADL-2500 fan-cooled Dry Dummy Load, $219.95

Whisper quiet fan, 2.5kW/1 minute on, ten off. 300W continuous. SWR< 1.25 to 30 MHz.<1.4 to 60 MHz.

SDA-100 Mobile Screwdriver Antenna

$409.95 80-10M, fiberglass form, Pittman motor, CNC parts, magnetic sensors, #14 wire, 1.2 kW PEP. 6' whip, $24.95

800 Watts . . . $999
with four 811A tubes

AL-811H, $999. Plugs into 120 VAC outlet. All HF bands. Hi-silicon transformer, heavy duty tank coils, tuned input, operate/standby switch, Xmit LED, ALC, lighted meters, 32 lbs. 13¾Wx8Hx16D in.

AL-811, $849. Like AL-811H, but three 811A, 600 W.

Desktop Kilowatt
with Classic 3-500G tube

AL-80B, $1595. Whisper quiet 3-500G desktop amp gives *full* kilowatt SSB PEP output. Plugs into 120 VAC. Ameritron's exclusive *DynamicALC*™ doubles average SSB power out and *Instantaneous RF Bias*™ gives cooler operation. All HF bands. 48 lbs. 14Wx8½Hx15½D in.

True Legal Limit™
with 3CX1500/8877 tube

AL-1500F, $3295. Ameritron's *most powerful* amplifier uses the herculean 3CX1500/8877 *ceramic* tube. 65 Watts input gives you full output power -- it's just loafing with a 2500 Watt power supply. All HF bands, all modes. 77 pounds. 17Wx10Hx18½D inches.

AL-1500, $4195, Eimac® tube.

1500 Watt* True Legal Limit™ *Antenna Tuner

ATR-30, $599.95 • Super high current edge-wound silver plated roller inductor • 500pf capacitors • 6:1 reduction drives • 3 core current balun • 6 position antenna switch • True *peak* meter

When a simple wire antenna is either all you want or all you can use for your low-power station, consider an end-fed half-wave (EFHW) with KI6SN's combo tuner and SWR bridge.

A QRPer's 40- through 17-Meter EFHW Antenna Coupler with Super-Sensitive SWR Bridge

BY RICHARD FISHER,* KI6SN

Some radio amateurs are QRPers by choice, leaning on efficiencies of their radios, antennas, and operating skills for the thrill of logging contacts up the block and around the world with transmit power of 5 watts or less. Others are QRPers by necessity. They live in cramped quarters where the guy next door's TV, AM-FM radio, and WiFi may be only a thin wall away. Even a 100-watt transceiver will cream them, let alone a kilowatt. Besides, the apartment manager or homeowners association may say outdoor antennas are *verboten.* Therefore, the op hunkers down at 5-watts output or less and lets necessity drive an aerial solution.

For all sorts of good reasons, the end-fed half-wave (EFHW) wire antenna with a counterpoise has been a popular means to that end—for good reasons. They are:

- Simple, inexpensive systems to make
- Suffer no feed-line loss, because *there is no feed line*
- Can be selected for the band or bands of operation based on what your real estate will bear, whether indoors or outdoors
- Need only one support to be erected

*(**IN DEPTH:** What is a counterpoise? Visit:* <http://bit.ly/19mwy9t>.*—KI6SN.)*

Of course, there is no free lunch. The catch here is that your transceiver is looking at an EFHW antenna impedance running in the range of 1,800 to 5,000 ohms—certainly not the 50 ohms for which your radio was designed.

Fortunately, there is a very simple solution. It is one that can be achieved through the work of your own hands:

Build an EFHW antenna coupler, and throw in a *super-sensitive* absorptive SWR bridge to boot (photo A)! We'll call it the *40- through 17-meter EFHW Antenna Coupler with Super-Sensitive SWR Bridge,* which grew from the ideas of two outstanding radio amateurs, who we'll get to in a minute.

First, a Word from Our Sponsor

There are, no doubt, some skeptics getting ready to turn the page. *"An end-fed antenna with a cheesy coupler at QRP levels? What kind of success can you expect with a lame set-up like that?"*

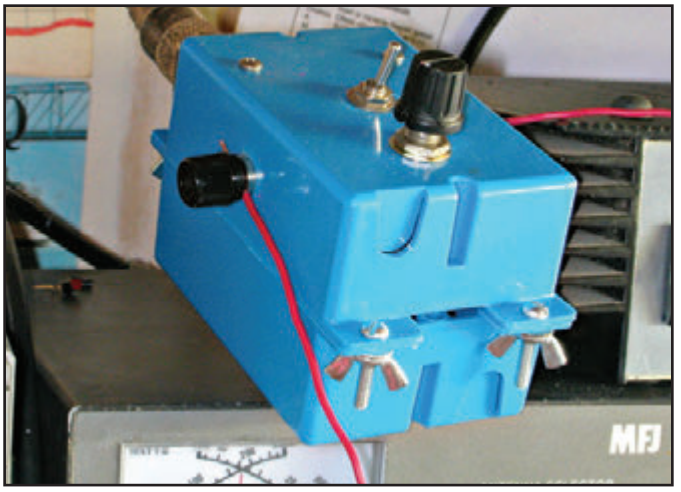

Photo A. With just a handful of parts and a couple of hours at the workbench, this 40- through 17-Meter EFHW Antenna Coupler with Super-Sensitive SWR Bridge *can be your ticket to getting on multiple bands with just a wire antenna and counterpoise. (Photos by KI6SN)*

Believe me, and others who swear by (*not at*) EFHW antennas: They work, even at 5-watts RF output. They can work *really well.*

Here's a KI6SN testimonial. After finishing this coupler-SWR bridge project and:

- Drooping the transceiver-end of a 66-foot, 40-meter half-wave wire from my operating bench through the rafters to the front of the garage ...
- Folding the wire back on itself across the roof to a PVC pole held to a pipe with a bungee cord ...
- And turning the wire 90 degrees horizontally to be tied off at the chimney ...

... We laid a 33-foot long counterpoise on the garage floor out onto the driveway and got on the air.

It was the Sunday morning of the CW leg of the CQ World-Wide DX Contest last November. I tuned the Kenwood TS-140S to 40 meters and peaked the SWR bridge for the best

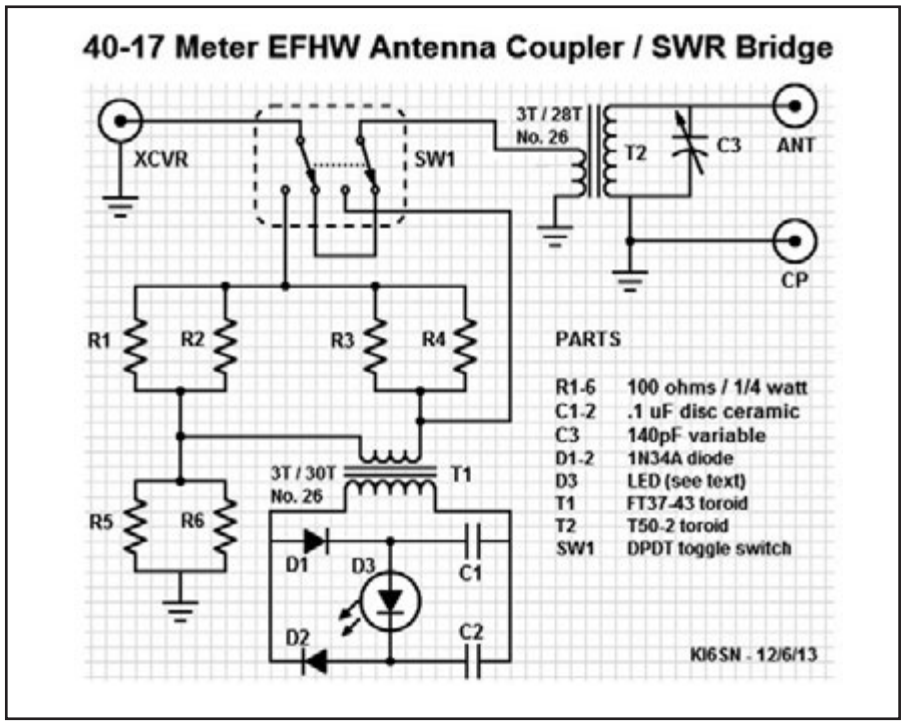

Fig. 1. Note that one wire crossing another without a dot means there is no connection between the two. For example, look at SW1. There are four solder points, left to right, shown at the bottom of the DPDT. Points 2 and 4 are connected, but do not connect to the wire going down and right from point 3. (Courtesy of KI6SN)

match. Running a full "QRP spoonful" (5 watts), I rattled off 14 Japanese stations, a Russian near the border of Mongolia, a Hawaiian, and several Canadians—all in the course of an hour around southern California local sunrise.

Later in the day on 17 meters —with an 18-MHz EFHW dangling about five feet off the garage floor—Randy Dominicak, WA6RKK, just south of the Canadian border in Rathdrum, Idaho, gave me a 5-7 on SSB. Again, I was running 5 watts. This time, though, with a completely "indoor" EFHW wire and counterpoise lying on the garage floor.

Yes, it's a tribute to WA6RKK's and all the DX stations' great operating skills, antennas, and receivers. By the same token, though, it proved an EFHW antenna, for all its simplicity, can be an amazing radiator.

Great Minds ...

When setting out to build a coupling unit capable of multi-band operation, we turned for inspiration to two experts in the amateur radio antenna game:

• Steve Yates, AA5TB, of Fort Worth, Texas, generally considered the world's

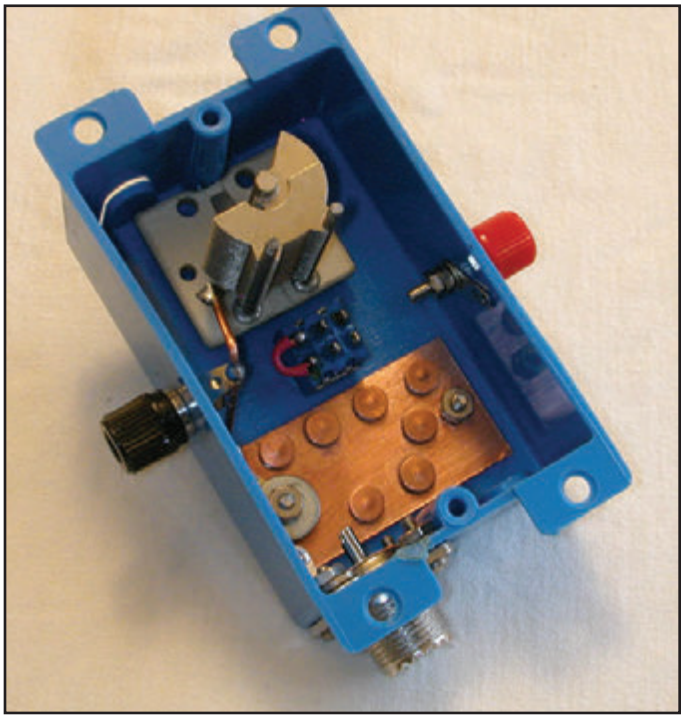

Photo B. The 140-pF air-variable capacitor, where the coupler circuitry will be positioned, is at the top of the box. The SWR PC board, with seven Manhattan pads attached, is at the bottom.

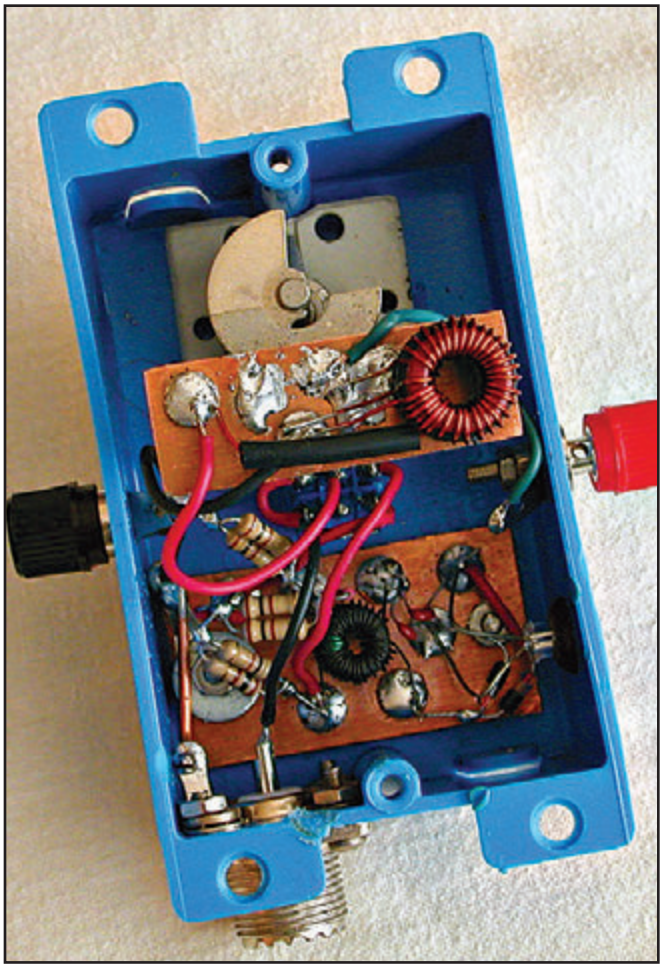

Photo C. It doesn't take long for 8 cubic-inches to be filled with antenna coupling and SWR-sensing components.

leading authority on EFHW antenna coupler design and operation. Visit his website for a textbook's worth of EFHW information at <http://bit.ly/ 1eMGWeL>.

• Glenn Leinweber, VE3DNL, of Hamilton, Ontario, Canada, recognized for his pioneering work in absorptive standing-wave ratio (SWR) bridges, made specifically for QRP operation. The catalyst for using one of his designs came from *An Improved LED SWR Indicator* under VE3DNL's byline appearing in the Spring 2000 edition of the NorCal QRP Club journal *QRPp.*

Of course, the coupler helps your transceiver "see" 50 ohms impedance going into your EFHW, while the SWR bridge allows the operator to "see," via light-emitting diode (LED), when a good match is achieved.

Settling on a Design and Finding Parts

An element from each expert's portfolio makes up the *40- through 17-meter EFHW Antenna Coupler with Super-Sensitive SWR Bridge* design. The schematic is shown in fig. 1. The portion of the circuit beneath SW1 comes from VE3DNL. Everything from T2 to the right is AA5TB's.

There are only a handful of parts needed for this coupler-SWR bridge combination, and many of the parts you may already have on hand. All are available through various parts houses.

Here are some examples:

• **R1-6,** 100 ohm, 1/4-watt resistors (RadioShack® <http://bit.ly/1eSTCRk>)
• **C1-2,** .1-µF capacitors (RadioShack® <http://bit.ly/1bjsyX9>)
• **C3,** 140-pF air-variable capacitor (Hendricks QRP Kits <http://bit.ly/1aCZ1aK>)
• **D1-2,** 1N34A diodes (Dan's Small Parts <http://bit.ly/1bKdKXI>)
• **D3,** LED (RadioShack® <http://bit.ly/1cd49nd>)
• **T1,** FT37-43 toroid (Dan's Small Parts <http://bit.ly/1bKdKXI>)
·**T2,** T50-2 toroid (Dan's Small Parts <http://bit.ly/1bKdKXI>)
• **SW1,** DPDT toggle switch (RadioShack® <http://bit.ly/Iuf3gS>)

For sure, there are many other parts sources for each of the components. By all means, shop around!

Sundry Hardware and Wire

With the exception of nuts and bolts, hardware can be found at RadioShack®:

• Binding posts <http://bit.ly/1d1DlZc>
• SO-239 coax connector <http://bit.ly/1kfFdQp>
• Rubber grommets <http://bit.ly/18FKktA>
• Hook-up wire <http://bit.ly/1dSMs2W>
• Magnet wire <http://bit.ly/1bkdFYV>
• Dual-sided PC board <http://bit.ly/18odZl6>

Once you've built the coupler/SWR bridge, the effort expended in gathering the parts and putting it together will pale in comparison to the enjoyment you'll have in using it.

Let the Soldering Begin!

I decided to construct the unit using Manhattan construction – using small copper-clad pads as solder points for the circuit's components. ***(IN DEPTH:** What is Manhattan construction? Details at* <http://bit.ly/1cXg5em>.*—KI6SN.)*

After scribbling out the point-to-point pad placement based on the schematic, I glued the seven pads on a printed circuit board (PCB) ground plane that had been sized specifically for the enclosure. By the way, the enclosure came from Home Depot. More on that later.

The air variable was mounted at the top of the enclosure where the tuning circuit would be (photo B). The PCB ground plane would go at the bottom of the box—home to the SWR bridge.

When AA5TB's and VE3DNL's circuits were completed, they'd be wired together and connected to the SO-239 coaxial cable transceiver input connector and the antenna (red) and counterpoise (black) binding posts. *(**NOTE:** In fig. 1, input is indicated as XCVR. The antenna is ANT and the counterpoise is CP.—KI6SN.)*

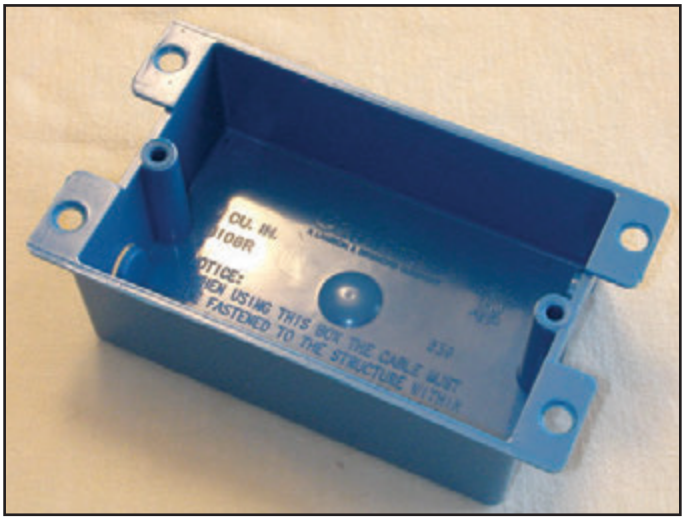

Photo D. Two Carlon 1-Gang, 8 cu. in. Old Work Flanged Shallow Boxes can make a great enclosure for this coupling/SWR bridge unit. Get a pair at Home Depot for less than $3.

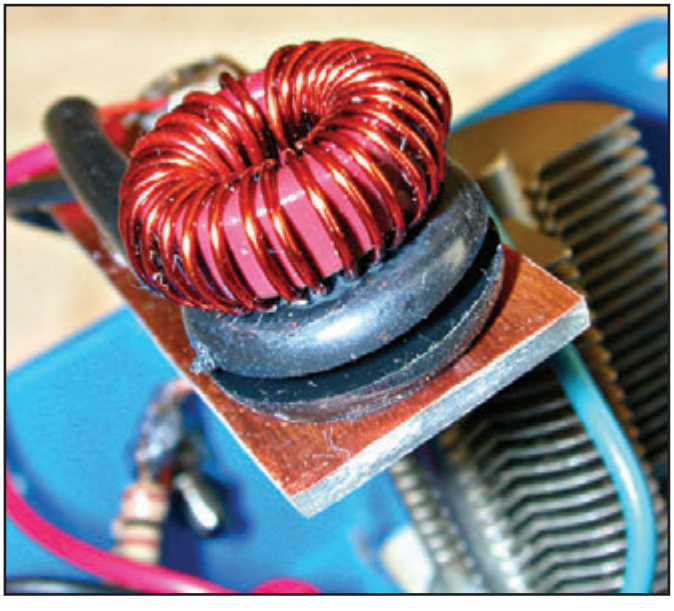

Photo E. Rubber grommets are used not only to insulate the toroid inductors from the PC board ground planes, but to add "shock absorption" to the transformers when the coupler/SWR bridge is being jostled around in a backpack.

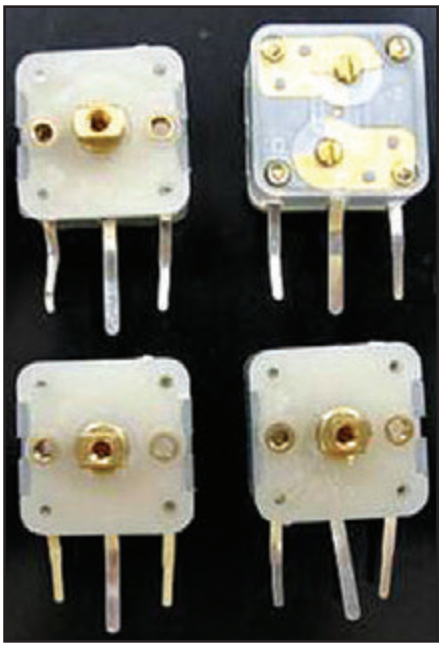

Photo F. There's no need to use an air-variable capacitor for C3. Polyvaricons, each with a 160-pF section, from Hendricks QRP Kits will work beautifully in this circuit. (Internet screen grab)

Since VE3DNL's SWR bridge is *absorptive*, it must be switched IN when tuning for lowest SWR and OUT when tuning is completed. That's the DPDT toggle switch's job. Only then is the operator ready to make contacts.

A view of the completed coupler/SWR bridge is shown in photo C.

What Makes VE3DNL's SWR Bridge 'Super Sensitive?'

VE3DNL branded his accessory *"An Improved LED SWR Indicator."* Here's why:

"To improve SWR sensitivity," he wrote in *QRPp,* "the RF voltage across the bridge arms should be made larger. A broadband RF step-up transformer is required. *(That transformer is made up of the primary and secondary windings on the FT37-43 toroid.—KI6SN.)*

Leinweber pointed out that many LED-based SWR bridge-indicators have a "dead zone" below 2 volts peak-to-peak, resulting in "the sensitivity problem." Back around 2000, "a test with a 2.7-watt transmitter was made to see how high the SWR had to rise before the LED glowed visibly," VE3DNL said. "For SWR below 1.3:1 no light (from the LED) could be seen. With the antenna short-circuited, (infinite SWR), the LED was blindingly bright."

The operator's goal is to tune the circuit so that little-or-no light is coming

CAUTION

Beyond this point:
Radio frequency DX at RemoteHamRadio sites may exceed FCC rules for human excitement.

Operate from restricted HOAs, apartment buildings, your vacation home, or even your home shack – all without the costs and headaches of maintaining a tower. Experience operating world-class stations across the U.S. and abroad with a real radio, not a clunky software-based solution.

EFHW Antenna and Counterpoise Data

BAND	FREQ.	ANT	CP
40	7.15	65.45	32.73
30	10.125	46.22	23.11
20	14.175	33.02	16.51
17	18.118	25.83	12.92

Frequency in MHz; ANT and CP lengths in feet and decimal feet

Fig. 2. Here are EFHW antenna and counterpoise lengths for 40 through 17 meters. Calculations were based on the frequency at the center of each band. (Courtesy of KI6SN)

from the LED, indicating an impedance match. *Therefore, dead zones such as described are just not helpful.*

"When the 1:10-ratio step-up transformer was added," Leinweber continued, "the same sensitivity test was run. For SWR above 1.06:1, light could be seen." *Much better.*

Leinweber assured that users need not worry about burning out the LED from too much current. In his "improved" circuit, "you actually get less light," he wrote. "With lots of LED current flowing, the RF impedance of the primary winding is very low. It is much lower than the resistive bridge arms."

As a result of this mismatch of impedance, "less RF power is transformed into LED power," he said. "The LED should survive infinite SWR, even when driven by a *full spoonful* (5 watts RF output)."

Project Notes

Enclosure: The piggy-backed plastic enclosures housing the coupler/SWR bridge were $1.20 each at Home Depot and are a mouthful if you ask for them specifically: *Carlon 1-Gang, 8 cu. In. Old Work Flanged Shallow Box.* They're in the electrical department, (See photo D.)

Note that wing nuts are used to hold the top and bottom of the piggybacked enclosure together. This is just personal preference. The two sides are easy to separate if there's ever a need to get inside.

This may sound strange, but: I put several Band-Aids® inside the unit. That way I won't have to think about having a few on hand when I'm on the trail. They don't hurt coupler or SWR bridge performance. And if there's ever a cut or scratch that needs to be attended, I can pop open the box and grab 'em. *Let the wing-nuts fly!*

Resistors: *Why are the 100-ohm R1-6 resistors in three parallel groups?* We want 50 ohms of resistance in each of the three legs. Anyone who has tried to find 50-ohm resistors knows they can be pretty scarce. So by putting two 100-ohm resistors in parallel, we achieve 50 ohms resistance (*remember Ohm's Law—ed.*). Since each resistor is rated at one-quarter watt, that gives us one-half-watt power dissipation in each leg, as well. It's never good practice to "key down" for more than a couple of seconds when tuning up, so the half-watt rating is sufficient at QRP levels.

Inductors: There are two transform-

ers wound on toroids in this design, T1 and T2. Number 26 magnet wire is used for both the primary and secondary windings of each. Note that the 3-turn primary winding of T1 is wound over the middle of the secondary winding. The 3-turn primary of T2 is wound over the *ground end* of the secondary.

When winding is completed, T1 and T2 are glued to rubber grommets, which in turn are glued to the surface of the PC board. *Why?* The grommet separates the inductor from the copper ground plane and acts as a "shock absorber," as well—a nice feature for operators who like to operate trail-friendly radio, photo E. Things can get banged around quite a bit in the field, you know!

Variable capacitor: At KI6SN, a 140-pF air-variable capacitor was used at C3. I'll admit: that's overkill. Hendricks QRP Kits has 160-pF polyvaricon capacitors that are much less-expensive than an air variable. At QRP levels, they will work perfectly well in this circuit. Visit <http://bit.ly/1aCZ1aK>, photo F.

LED: A RadioShack® 5mm Red Wide Angle LED (RS 276-309) was used in the KI6SN version. By all means, though, experiment with any LED you have lying around. It's important to orient the LED properly in the circuit. When holding an LED in your hand, you'll note it has one lead longer than the other. That distinguishes its *cathode* from its *anode.* In fig. 1, the LED's long leg (anode) goes to the junction of D1-C1. The short leg (cathode) goes to the junction of D2-C2.

LED position: You may be wondering why the LED is not pushed through the grommet so it protrudes from the box at the right of the red binding post, photo G. Two reasons:

• If it protrudes, the LED could be damaged when the unit is knocking around on the trail.

• By recessing the LED, it's much easier to see when you're tuning in bright sunlight.

Make it your preference, though—*protrude if you'd like!*

The Easy Part: Making the ANT and CP

OK, it's time to put this jewel in line and on the air. The 50-ohm coax from your transceiver goes to the SO-239 antenna connector on the coupler/SWR bridge.

Now, on what band would you like to operate? Thirty meters might be interesting. Go to fig. 2 and note the figures:

At 10.125 MHz, the middle of the 30-meter band, an EFHW wire must be 46.22-feet long. For simplicity, we'll round that to 46.25 feet, or 46 feet, 3 inches. Pull out your roll of No. 22 insulated stranded hookup wire, measure and cut. *There's your antenna. (**CHECK:** RadioShack® 90-Ft. 22 Gauge Hookup Wire* <http://bit.ly/18p5jOC>.*—KI6SN)*

Referring again to fig. 2, note that a counterpoise for an EFHW 30-meter wire is 23.11 feet—or about 23 feet, 1 1/2 inches. Again, grab that roll of No. 22 stranded wire, measure and cut. *There's your counterpoise.*

Connect the 30-meter 46-plus-foot EFHW wire to the antenna (red) binding post and the corresponding 23-plus-foot counterpoise to the black post. Stretch the counterpoise from the coupler along the ground as straight as you can. Now put the EFHW antenna as straight and high as you can. *(**CAUTION:** Whether you're outside or inside, take care that these wires do not come in contact with any electrical wires, appliances and so on.—KI6SN)*

Whistling a Happy Tune-Up

Once the antenna and counterpoise are in place, it's time to match the antenna to your transceiver.

• Connect your coax from the transceiver to the coupler.

• Flip the DPDT switch to the TUNE position—the side of the switch that incorporates the SWR bridge.

• Find a clear 30-meter frequency and *briefly* key down on CW using the least amount of power possible to get an indication on the LED. You can increase to 5 watts if you like *after* the tuning procedure is completed.

• During key down, chances are the LED will be shining brightly from inside the grommet.

• In no more than a few seconds, turn the variable capacitor (C3) until the LED either dims or goes out completely.

• *Key up!* You've found the matching point.

• Flip the DPDT switch to OPERATE, bypassing the SWR bridge.

Whistle a happy tune! QRO (increase power)—up to a full *QRP spoonful*—if you'd like, because you're ready to get on the air. *Halleluiah!*

Return to fig. 2 and cut another EFHW antenna and counterpoise for another band. And another. And another. *What fun!*

Now It's Your Turn

It's a pretty simple antenna system, wouldn't you say? If a matching unit and SWR indicator are the only things standing in your way, build the *40- through 17-Meter EFHW Antenna Coupler with Super-Sensitive SWR Bridge*. You won't be disappointed, and with such a nice slice of amateur spectrum within reach—either on the trail or in your condominium or apartment building—you may be amazed by your success! I certainly was.

W2IHY Technologies
Outstanding Transmit Audio Is Our Specialty
8 Band EQ
W2IHY 8 Band EQ & Noise Gate Thousands of Satisfied Users Worldwide
Add the legendary W2IHY 8 Band Equalizer And Noise Gate to your shack and get ready for great audio reports! From smooth rag-chew audio that makes them ask what you're running ... to penetrating DX/Contest audio that gets results, wide-range adjustability is at your command. Noise Gate reduces background noise for a cleaner, more effective signal. Universal Interface lets you use most any microphone with any radio including classics. I-K-Y selector for plug-n-play with popular brand micro-phones. Switched outputs for 2 radios. Headphone Monitor. RFI protection.
EQplus By W2IHY
Premium Audio Processing
Did you turn on an amplifier? Your signal is loud and squeaky-clean. EQplus users hear that report all the time. Compressor/Limiter increases talk power without the distortion and restricted frequency response of ordinary speech processors. Dual Band EQ, Downward Expander for noise reduction, Effects for psychoacoustic magic. LED Bar Graph. Front panel controls. Universal Interface matches most all mics, all radios. I-K-Y mic selector. Switched outputs for 3 radios. Headphone Monitor. RFI protection. Powerful stand alone system or combine with W2IHY 8-Band EQ for maximum adjustability.
Products purchased from W2IHY include 30 Day Money Back Guarantee and 3 Year Parts/Labor Warranty.

So here we are at the supposed peak of the weakest sunspot cycle in decades. What's a QRPer to do when the HF bands aren't open? WA6ARA has one suggestion: Look up!

Satellites and the QRPer . . . or Don't Worry About Sunspots

BY MIKE HERR,* WA6ARA

Imagine for the moment a new band, with propagation out to about 3000 miles. Band openings are brief but extremely predictable. Further, it is perfect for QRP operation. You tune across the new "band" at the appointed time and, suddenly, there are signals, some operating in contest style, others in a ragchew. CW and SSB can be heard. You join in, work many stations or just chat with a friend, all with modest antennas and low power levels. And again, at a predictable time, the "band" closes. The "band" I am describing does exist. It's called amateur radio satellites.

Amateur radio satellites, or OSCARs (Orbital Satellite Carrying Amateur Radio), are satellites orbiting above the Earth that contain equipment to relay amateur radio signals great distances. They represent a solution to poor propagation, the need for high power, and the need for large antennas. Many hams consider the use of amateur radio satellites as "fringe," only for the extremely technically inclined amateur, requiring high power, massive antennas, and intricate rigs. This is simply not so. The equipment is readily available, antennas are small, and the required power levels are low. In fact, low power is preferred. Many hams, including QRPers, already have some or all of the equipment that is needed.

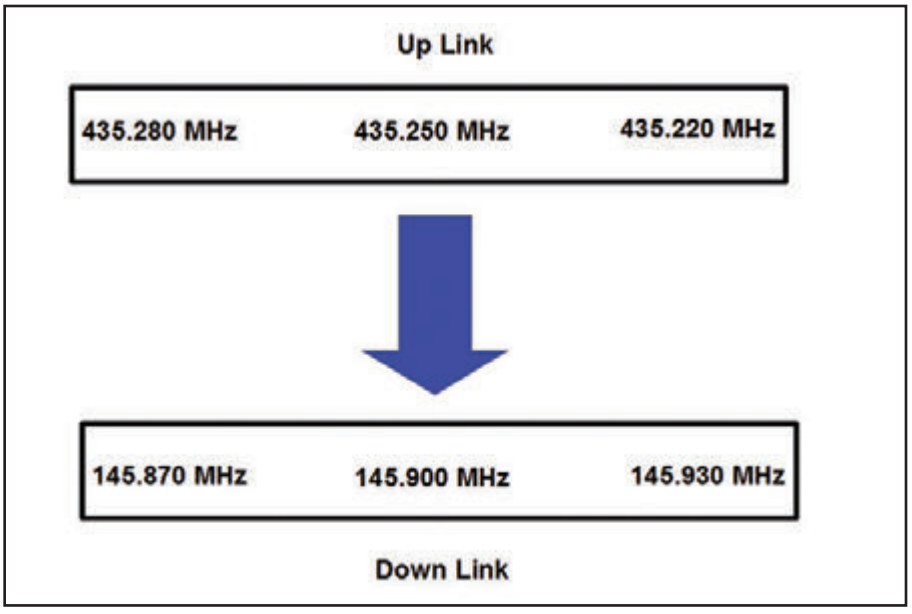

Fig. 1. How a satellite linear transponder works. All signals coming in on the uplink are retransmitted on the downlink. Note that this is an inverting transponder, so the "top" of the uplink passband is the "bottom" of the downlink passband, and what goes in on lower sideband comes out on upper sideband!

Different Satellite "Flavors"

There are basically three types of amateur radio satellites. The first are those doing some sort of scientific mission and using amateur radio frequencies to transmit their data. While it's interesting to track and decode the telemetry, these satellites are not useful for amateur radio communication (although some are opened for amateur use once the scientific mission is completed).

Next are the FM and digital satellites. These are repeaters and digipeaters in the sky. Like their terrestrial cousins, they allow only one user at a time, on a single frequency. These are the so-called "easy sats." You can work them with a handheld, *if* everything is optimum. SO-50[1] is an example of an FM "easy sat."

However, the main interest for the QRPer is the group of satellites containing *linear transponders*. The linear transponder (see fig. 1) takes a portion of one band, amplifies, filters, and heterodynes it to another band. SSB and CW are the primary modes. FM could be used but is *strongly discouraged* due to the bandwidth and 100% duty cycle.

Footprints

Each satellite has a *footprint*, that area of the Earth that it can see. The size of the footprint depends upon the orbital height of the satellite. Anyone inside the

*613 N. Rebel Road, Ridgecrest, CA 93555
e-mail: <wa6ara@gmail.com>

footprint may communicate with anyone else inside the footprint. How long you can access the satellite depends upon its orbital speed, which is inverse to its height—i.e., the higher the satellite the slower its ground-path speed and the longer its visibility over any given point on the planet.

High Earth orbit satellites such as AO-10, AO-13, and AO-40 could effectively see half the Earth at a time and would do so for hours. Unfortunately, those magnificent birds are no longer functional. Our present crop of satellites has a more muted footprint and shorter accessibility times. The satellites are constantly moving, so your mutual window with any particular station may only be 5 to 10 minutes long. Fig. 2 shows the footprint of satellite AO-7 on a typical pass.

Amateur radio satellites are QRP-friendly, and low power is encouraged. On the linear transponders, an excessively powerful signal uses a disproportionate amount of the total power available to the transponder. This can cause distortion, drive other signals to become weaker, or even cause the satellite to shut down.

How much power do you need? This depends upon your antenna system. With a modest antenna and a 5-watt signal you can often work across the country. Photo A shows Dave, KB5WIA, having a nice roundtable QSO with W7JPI, VA3JW, WA6DIR, and XE1AO on satellite AO-7. The location is one of the most remote parts of the continental USA, Racetrack Valley, within Death Valley National Park. Note that Dave is using two Yaesu FT-817 transceivers barefoot for the QSO (see below for the reason two radios are needed). Often on a high-angle pass of the satellites I have had great QSOs with only 2 watts of power.

Station Equipment

Many contemporary HF radios have VHF and UHF capability. The FT-817, long a favorite of the QRPer, or the ICOM IC-706, each contain much of the capability you need to operate the satellites. The Elecraft KX-3 with the 2-meter module will also make an excellent portion of the station. If so inclined, as many QRPers are, equipment may be homebrewed.

At a minimum, you will need one radio to transmit and a second one to receive, unless your radio can simultaneously receive on one band and transmit on another. It is very important to be able to listen to your signal. Why? First, to make sure you are not using too much

Photo A. Dave, KB5WIA, having a roundtable QSO on the AO-7 satellite from Death Valley National Park in California, one of the most remote parts of the continental USA.

power! You don't want to be the "lid" who causes the satellite to distort or shut down. QRPers will not have this problem! The second reason is to track your own signal. The satellite is moving, a lot, on the order of 17,000 mph. While operating, the signal will seem to drift. It isn't; it is the Doppler Effect.

As the satellite approaches your station, the frequency will be high, and as it passes and recedes, the frequency will drop. The same can be observed with a passing train. The sound of the horn changes frequency as it passes. By being able to separately adjust the receive and transmit frequencies, and hear your own signal, you can compensate as well as knowing if you are being heard.

If you have a computer and CAT-controlled radios, then the computer can adjust the radios for the Doppler shift. Otherwise, for manual control, the rule

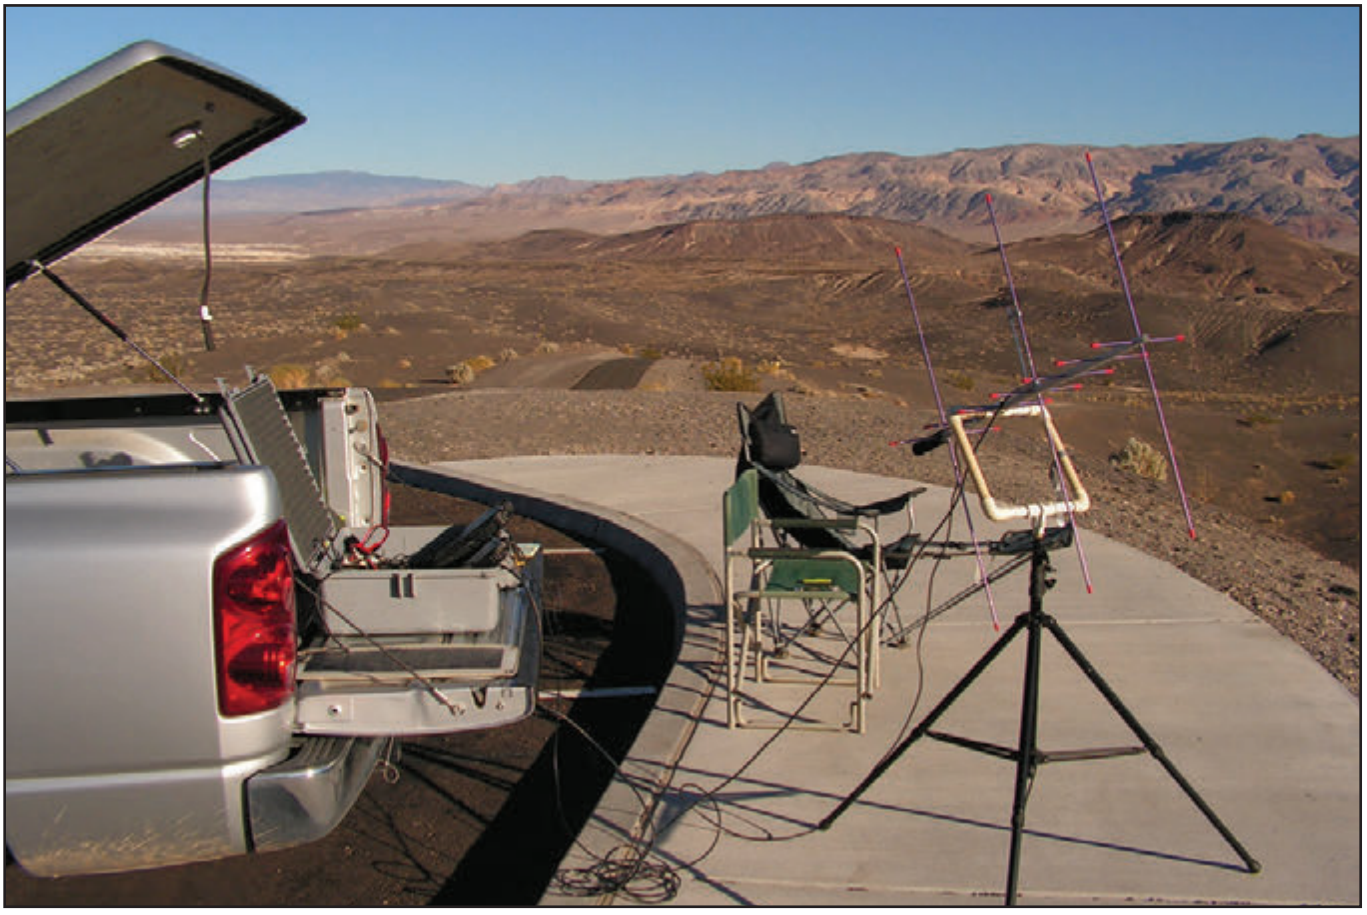

Photo B. The author's portable satellite setup at the edge of Ubehebe Crater in Death Valley, California.

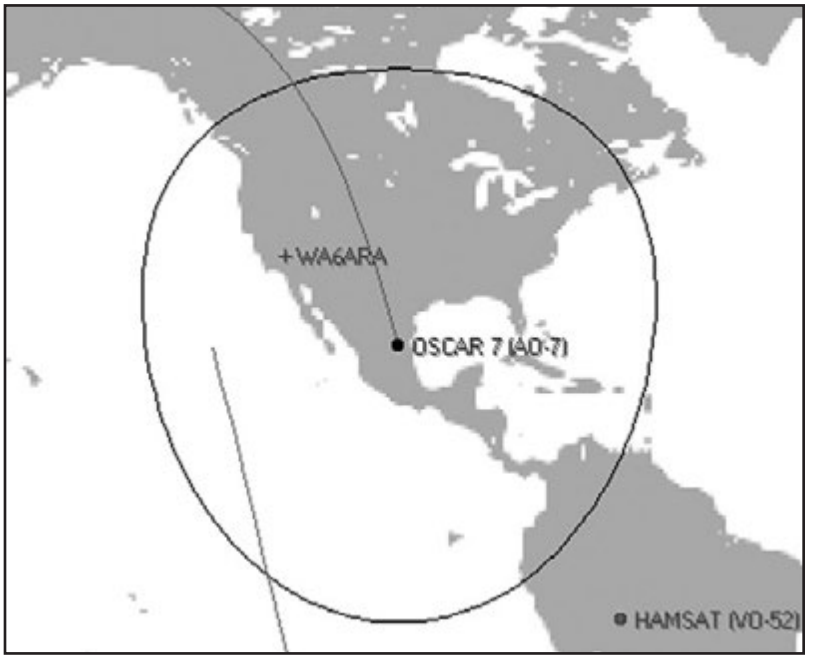

Fig. 2. "Footprint" of OSCAR-7, a nearly 40-year-old satellite that is still going strong. Any two stations within that "footprint" may communicate with each other via the satellite.

of thumb is to adjust only the *higher* frequency of the uplink or downlink. For example, on VO-52 you transmit on 435 MHz and receive on 145 MHz. Leave the receive frequency alone and only adjust the transmit frequency. Mark Spencer, WA8SME, has developed a way to computer control a single FT-817 for both transmit and receive, and to compensate for Doppler.[2] While you will not be able to hear yourself, at the 5-watt level you are not at risk of exces-

Where Are the Satellites?

There are a couple of ways to track amateur radio satellites, either online or with a computing device. Just about any computer will work … desktop, laptop, tablet or phone. Various programs and apps exist, some free, some for a nominal fee. All work well. Also, you will need what is called the *Keplerian elements* for the particular satellite of interest. These are the mathematical values which describe the orbit of the satellite, originally developed by Johannes Kepler in the 17th century. (Of course, he had no idea at the time that his calculations would someday be applied to manmade satellites.)

Online tracking has the advantage of not having to worry about the latest Keplerian elements. AMSAT has an excellent quick look tool at <www.amsat.org/amsat-new/tools/predict/>. Another one is at <www. heavens-above.com>. It has a specific tab for amateur radio satellites. Just open it, enter your location and select the satellite you want. You can get the pass info for several days if desired. The downside is that it only gives you the start location of the pass, the highest point and then the end-of-pass location. It is up to you to mentally interpolate the times and points in the sky as to where the satellite is during a pass. It sounds hard, but really isn't if you are moving the antenna manually. Another negative to online tracking is that you can't slave a rotor or radios to automatically follow the satellite in terms of location or Doppler shift.

If you want to use a computer, then there are a number of options available. For Windows®, the program **Satpc32** is considered the best and has a large support base. It is available for a nominal fee at the AMSAT store <http://store.amsat.org/catalog/index.php?cPath=2>. Also at the AMSAT store is **MacDoppler** for Mac users.

In the freeware world is the excellent program **Orbitron** at <www.stoff.pl>. Linux users should check out **gpredict** at <http://gpredict.oz9aec.net/>. All of these allow for the automatic updating of Keplerian elements as well as slaving the rotors and radios to the computer for automatic tracking and Doppler correction.

Tablet and phone users, especially those with the Android system, should check out **AmsatDroid** at the apps store. While you can't drive the rotors or radios with it, it does give you a nice listing of available passes as well as a world map showing the satellite's location. For the iPhone user, try **HamSat** or **ProSat**, available at the iTunes Apps store.

Your First Satellite Contact

Your first satellite contact, just like your first HF or VHF contact, can be very trying, even for a seasoned ham. I would recommend reading the "Getting Started" series at the AMSAT website <http://www.amsat. org/?page_id=1869>. While somewhat dated, it is still good information.

If the FM satellites are what you are interested in, then a good tutorial for SO-50, presently the only FM satellite we have, is at <www.g6lvb.com/articles/operatingso50.htm>.

For the linear transponder "birds," here is a plan:

First, I will assume you have the antennas and the radios ready to go. I am also going to assume that for your first contacts, you will be doing everything manually. What satellite to go after? I strongly suggest VO-52. It is very strong and reliable. Look at the available passes for your location. Select a time and pass with a high degree of success probability. Weekends tend to be more popular than weekdays; evenings tend to do better on the weekdays and daytime on the weekends. Think about who your audience might be. If you are on the west coast, don't select a pass that is largely over the Pacific Ocean. And don't pick a low-angle pass. While these hold the promise for the most DX, a nice high-angle pass, say above 45 degrees, will be easier for getting started.

Next, get everything ready at least 15 minutes prior to the start of the pass. You don't want to be searching for a coax adapter as the satellite comes up over the horizon. Know which way north is. That sounds simple but you want to know exactly which way *true*, not magnetic, north is as well as other compass points.

For this first pass, I suggest you only listen, do not transmit. Why? All of this is new—tracking time, azimuth and elevation angles as well as frequency—so eliminating transmitting will help out the first time. Select an open area, preferably one without trees or buildings to block your sky view. Have the pass information in front of you, receive radio all powered up, set to upper sideband (more on this later), and the antenna pointed at the approximate location of the beginning of the pass.

The appointed time has come! Start tuning around the satellite's downlink passband, mostly at the center. For VO-52 this is 145.900 MHz. Tune up and down about 15 kHz. Soon you will hear a voice or two, or maybe a CW signal. Move the antenna in both azimuth and elevation to maximize the signal, but keep your eye on approximately where it should be in the sky from the tracking information. More than once I have found myself tracking a satellite using a minor lobe of my antenna and wondering why it is so weak.

Once you find a QSO, listen and see how it is done. Typically, you will find two different types: the fast contest-style QSO and the rag chew. Sometimes the rag chew turns into a big round-table with stations checking in as the satellite comes within their view and others falling off as it leaves. You may have to touch up the receive frequency a bit during the pass. When the pass is over, it is over.

Once you have mastered the receiving end of things, it's time to transmit and hold a QSO. The setup is the same except for the transmitter. For VO-52, you will set it up at 435.250 MHz, lower side band. Why LSB? Because the transponder in VO-52 is *inverting,* so what goes in as lower comes out as upper, and upper sideband is the convention for satellite downlinks. The rest of the setup is the same as receiving.

Now the pass begins, and you hear someone calling CQ. The hard part is where to transmit. First, because the satellite inverts the signal, as you tune *up* in frequency on the uplink (435 MHz) it goes *down* in frequency on the downlink (145 MHz). And just to confuse you a bit more there is old Doppler messing with you. So I suggest you first go down to say 145.890 MHz and tune to 435.260 MHz transmit and send your call sign in CW. Tune with the receiver until you hear it. Once found, only tune the transmit side, not the receive side, of your radio set up. You might try this for a pass or two until you get the hang of finding where you are and correcting for Doppler. In fact, a good time to do this practice is at the times when you would not expect much traffic on the satellites, i.e. over the oceans or mid-day during the week.

Once you have the hang of it, try answering that CQ. Or call CQ yourself. Warning, it may take a time or two to get everything down with moving the antennas, correcting for Doppler and using two radios, but it will quickly become second nature. Adding computer control for antenna positioning and Doppler correction greatly reduces the overall workload and can make satellite operation a real pleasure. Enjoy!

The Next Step. After you have your feet wet on satellite operation, *become the DX*. Satellite operators love to chase Maidenhead grid squares. And the rarer, the better. I am in DM15, fairly rare, but I am on often, so it's not a big problem. I can drive a couple hours to Death Valley, though, and be in DM16 or DM17, which are rare indeed. When you get on the satellite from a rare grid, you can expect a pile up, as everyone wants your grid! Many of us live within a couple hours of grid squares that are rarely, if ever, activated on the satellites. So a day trip with a portable satellite station can be a lot of fun!

sive power and the Doppler correction is done for you. It makes for a nice single-radio package.

Satellite Antennas

Antennas really are the secret to successful satellite operation, just as they are for HF QRP work. For satellites, this means beams. Fortunately, the beam antennas necessary for 145- and 435-MHz operation (the primary bands for satellite operation) are relatively small and can be near ground level. Many operators use a simple tripod from the back yard or balcony, so there's no obvious antenna for the homeowners' association to get excited over.

For the homebrewer, *CQ* Antennas Editor Kent Britain, WA5VJB, has an excellent design for a 145-MHz/435-MHz antenna for satellite use.[3] It is effective, cheap, and simple to build. Commercial antennas by Elk[4] and Arrow[5] have been successfully used for portable and permanent QRP satellite operation. The Elk antenna is a 5-element dual-band log periodic. The Arrow antenna consists of a 3-element 145-MHz antenna with a 7-element 435-MHz antenna set at cross polarization on the same boom. I use one of these in the field with excellent results. Photo B shows my simple setup using an Arrow antenna at the edge of Ubehebe Crater, in Death Valley, California.

It is necessary to know when a particular satellite will appear and what its "track" will be as it crosses the sky. This can be worked out with home computers, tablets, or smart phones. Several excellent programs are available, both commercial and freeware. Once the satellite's pass is known, then the antennas need to track or follow the satellite during its "pass" over your location. At the home QTH, this is often done with rotors in both the azimuth (compass direction) and elevation (up and down) axes. The rotors may be driven by the computer, freeing up the operator of the tracking task. In the field, it is most often done by hand. Simply point the antenna at the approximate location in the sky and tweak slightly for best signal. A helper here is best, as the operator can easily become overtasked with tracking, frequency correction and operating.

Linear Transponder Satellites

There are presently three satellites in orbit with linear transponder capability. These include AO-7, FO-29, and VO-52. AO-7 is the granddaddy of them all. Launched in late 1974, it died in 1981, then amazingly came back to life in

2002. It operates only in daylight (when its solar panels are gathering energy) due to open batteries. The fact that a nearly 40-year-old satellite is still in service speaks highly of solid amateur radio engineering.

AO-7 contains two sets of transponders, one for 145 MHz up and 29 MHz down, and another for 432 MHz up and 145 MHz down. It cycles back and forth between the two transponders approximately every 24 hours. AO-7 is more susceptible to high-power distortion due to the lack of functioning batteries and QRP is very much welcomed here.[6]

FO-29 is another workhorse satellite.[7] Launched by JAMSAT (Japanese AMSAT) in 1990, it still performs well. FO-29's uplink is on 145 MHz and its downlink is on 435 MHz.

VO-52 was launched by India's AMSAT organization in 2005. This is a very strong signal satellite.[8] It receives on 435 MHz (uplink) and transmits on 145 MHz (downlink).

Looking in the Crystal Ball

What does the future hold for amateur radio satellites? Are you going to build a station just to have it be idle due to lack of satellites? No way! At the time of writing this article, several satellites which include linear transponders had just been launched. Their transponders will be activated once their primary scientific missions are completed, maybe about the time you are reading this. These include FUNcube-1 and Delfi-n2Xt.

This year should see the launch of FUNCube-2, KiwiSat, CAS-2A1, and CAS-2A2. In addition, a plethora of satellites with FM repeater capability are scheduled to be launched. AMSAT DL in Germany is actively working on an OSCAR-13 class satellite and there is word of AMSAT NA initiating work on a small "cubesat" satellite with high Earth orbit potential.

So the future is indeed bright. Check out the AMSAT NA web page (www.amsat.org) for specific information on these and future satellites, and consider joining AMSAT and supporting amateur radio satellites.

I have only touched on the use of satellites and QRP. Using satellites, the QRPer opens up a whole new field of operating. Power levels need not be high, antennas may be small and out of the way, homebrewing is encouraged, and the operating in the field, which many QRPers also enjoy, is perfect for including satellites. By all means, get on and give them a try!

BY IRWIN MATH,* WA2NDM

How to Properly Listen to a Restored Antique Radio

Last month, as you may remember, we described the restoration of an antique Atwater Kent radio receiver we obtained at an extremely low price at a local flea market. Well, now that we had a working 1930s era receiver, the thought that if we could listen to some of those actual radio shows of yesteryear on the radio would truly be nostalgic. To do this, however, we needed two things—a recording of some old shows and a suitable transmitter to send them to the radio. As it turned out, the old-show recordings were readily available on the internet (at very reasonable prices) and we purchased a CD with several of our favorites. The transmitter was another matter.

This month we will describe what we came up with. Before starting, you should also realize that this same technique can be used to build a simple low-power (QRP) AM transmitter for almost any amateur band.

For the most part, old radios were AM receivers covering the broadcast band from around 550 to 1500 kHz (1.5 MHz). What we needed, therefore, was a small, low-cost AM transmitter with a range of 10 to 20 feet. Our plan was to have the transmitter hidden in another room, modulated with the old radio show recordings and then fool our guests by telling them that somehow our old radio could pick up stations from the past! To keep things legal we had to limit the power of the transmitter to less than 100 mw into a 10-foot antenna to properly comply with FCC regulations. In the past this would have been done by means of a so-called vacuum-tube-operated "phono oscillator," but we wanted something much more modern and battery operated if possible.

Our first attempt was to use a surplus 1-MHz oscillator (ECS 2100AX-1.0MHz available from Mouser Electronics for less than $5) that we had on hand. This was a TTL unit normally intended for microprocessor clock applications, but since its output was pretty much in the middle of the broadcast band, it seemed like an ideal choice. Applying 5 volts, a 1-foot length of hookup wire as an antenna a foot or so from the radio, and tuning the radio to "100" on the dial resulted in a strong carrier. Now to try to AM modulate it.

Since the output of the oscillator would vary in amplitude from about 3 volts to 5 volts depending on the input DC provided, our first attempt was to simply vary the supply voltage to the oscillator by means of a 1K to 8-ohm audio output transformer that we had on hand. The transformer, a RadioShack 273-1380, was connected backward in the classical plate modulated circuit shown in fig. 1. We then applied a 400-Hz tone from our signal generator to the 8-ohm winding, our scope to the output of the oscillator, and then adjusted the input level until we got a sine-wave modulation envelope. The first waveshape shown in fig. 2 was what we could get, but the second waveshape is what was really desired. When actual audio was applied to the transformer, the sound was clearly present when received by the radio but somewhat distorted, probably due to the non-symmetrical downward modulation. In addition, there were several harmonics due to the square-wave output. Not perfect, but usable.

To clean things up we added a class C tuned amplifier stage to the output of the oscillator as shown in fig. 3. We also moved the modulation transformer from the oscillator to the amplifier, thereby achieving the final modulation waveshape we desired. This stage not only increased the output amplitude but also cleaned up the wave form to make it more sinusoidal and reduce higher order harmonics. In addition, you will note that we con-

*c/o CQ magazine

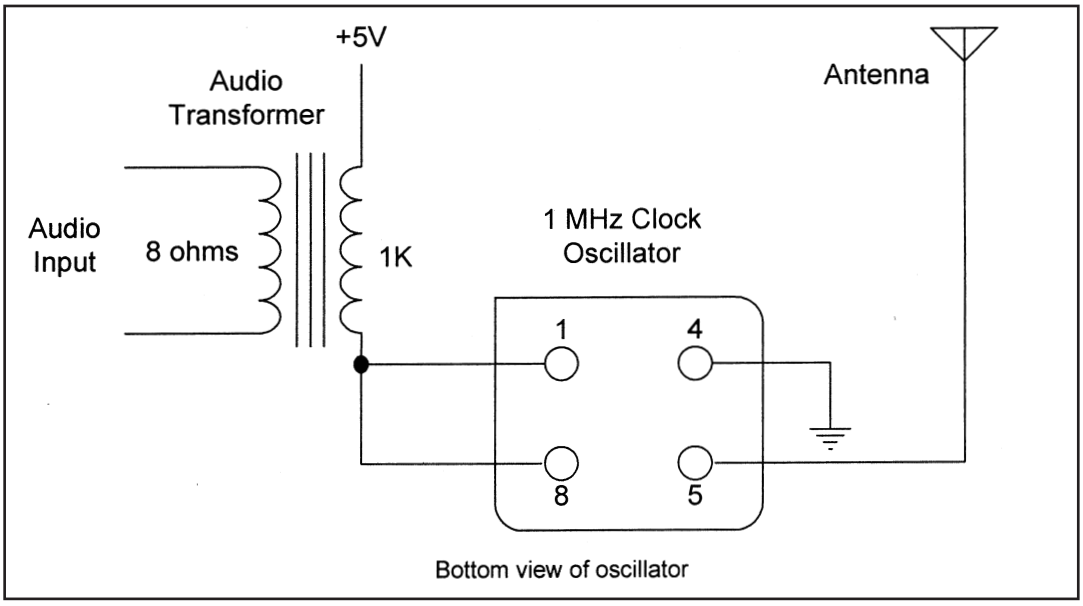

Fig. 1. Basic modulated AM "transmitter."

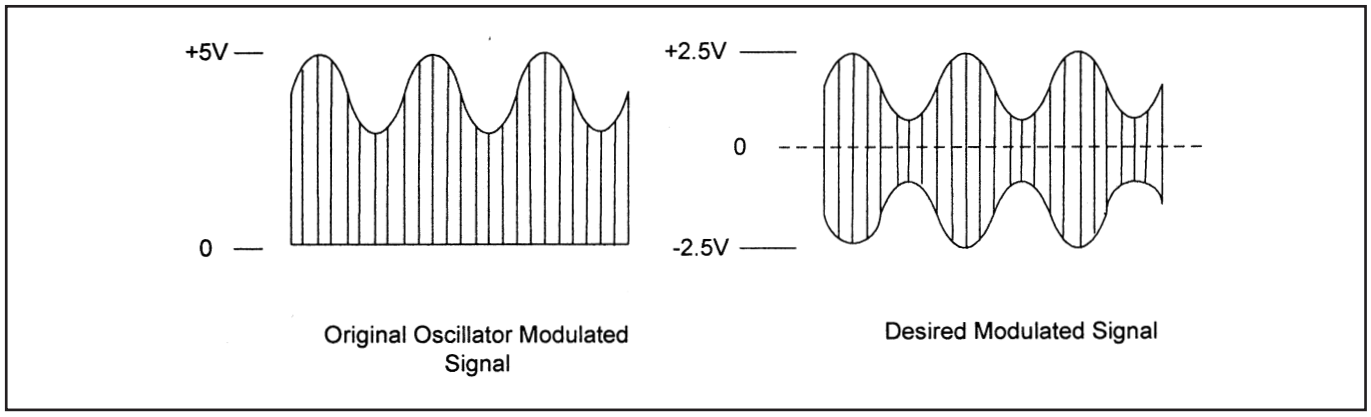

Fig. 2. Waveshapes from "transmitter."

nected the amplifier stage to 9 volts (for more output) and added a 3.9-volt Zener diode to drop the 9-volt supply to the 5 volts required by the oscillator. Note Ct and Lt. These values were chosen to resonate at approximately 1 MHz and were what we had on hand. You certainly can experiment with these values to peak the output signal as much as possible. When you do, adjust the values (and audio input level) as required to achieve a symmetrical modulated signal with no clipping (see fig. 2). Also, whenever using this type of circuit be sure to use only as much antenna length as you need to go a short distance. Too much and your audience may be the FCC!

As we mentioned before, you can use this same technique to build a low-power AM transmitter for any amateur band where you can purchase an oscillator with the correct frequency. Simply scan the catalogs of the various electronic suppliers and look for the frequencies available for clock oscillators. Then adjust the values of the tuned circuit as required for best results. You may be able to change the output transistor for a higher power device to achieve more output, and "key" pin 1 of many similar oscillators for CW operation, but that is a topic for another time. As a final reminder, be sure to check the data sheet for the oscillator you use. You will find additional information as well as any changes in wiring required for the particular unit you may have.

Our final result was a real nostalgic experience. What helped even more was that the old-time radio program CD we obtained also had commercials from the same time period. Under the right circumstances (if you were not in the 21st century) you would swear you were back in the golden age of radio! 73, Irwin, WA2NDM

EmComm in the Sky and on the Ground

SKYWARN Hails Volunteers, while "Spokespersons" get Support from Florida Hams

While a large portion of the Midwestern and eastern United States were heading into a freak pre-winter storm December 7–8, it was "82 degrees and sunny" at the National Hurricane Center in Miami.

If you're an NFL fan, you remember the weekend "Snow Bowls" from Philadelphia to Washington, D.C.; Baltimore to Pittsburgh.

owever, the balmy WX (weather) report from South Florida was what operators at the NHC's WX4NHC issued in QSO exchanges during the annual SKYWARN® Recognition Day (SRD), an all-Saturday on-air activity in commemoration of the organization's thousands of volunteers (photos A and B).

"This is a nationwide on-the-air communications exercise that recognizes volunteer SKYWARN spotters for their dedication and skills in providing the National Weather Service (NWS) and their communities with real-time surface reports during severe weather," Julio Ripoll, WD4R, said. For more than three decades he has been WX4NHC Amateur Radio Assistant Coordinator. "These surface reports help NWS forecasters and local authorities provide the public with advance warnings of severe weather."

SRD is sponsored by Scott Mentzer, NØQE, and Matthew Mehle, KCØTER, of the National Oceanic and Atmospheric Administration (NOAA) <http://www.NHC.NOAA.gov >.

According to the SKYWARN website, it is "a volunteer program with nearly 290,000 trained severe-weather spotters. These volunteers help keep their local communities safe by providing timely and accurate reports of severe weather to the National Weather Service." ***(IN DEPTH:** For complete SKYWARN information, visit <http://www.SKYWARN.org>. – KI6SN.)*

Although spotters "provide essential information for all types of weather hazards," the site notes, "the main responsibility of a SKYWARN® spotter is to identify and describe severe local storms. In the average year, 10,000 severe thunderstorms, 5,000 floods, and more than 1,000 tornadoes occur across the United States. These events threatened lives and property."

During 2013 SRD, radio amateurs from around the world were invited to check in with WX4NHC, giving a brief weather report. It's an opportunity, as well, to test the reliability of each operator's communications equipment.

During the daylong event, "We tested all of our equipment and antennas, including HF, VHF, UHF, EchoLink/IRLP, APRS, and other digital and on-line modes," Ripoll said from WX4NHC.

"Although the HF (high-frequency) propagation from South Florida was not very good, we were able to make 124 contacts on 15, 20, and 40 meters, including 22 NWS offices. The VoIP NWS/NHC Net—run by the SKYWARN group WX1BOX at NWS's Taunton, Massachusetts site—was a success. This net had scheduled many NWS offices and linked EchoLink and IRLP repeaters on Conference room WX-Talk."

Ripoll noted that WX4NHC's most distant contact and weather report was from Tony Langdon, VK3JED, of Long Gully, Victoria, Australia, who was operating mobile using an IRLP repeater.

The lowest temperature reported was from the Arrowhead SKYWARN Response Team, KØNWS, in Duluth, Minnesota. *How cold was it, Johnny?*

*1940 Wetherly Way, Riverside, CA 92506
e-mail: <ki6sn@cq-amateur-radio.com>

Photo A. Lloyd Kurtzman, W4KAM, left, and Julio Ripoll, WD4R, take their turn at the operating position at WX4NHC from the National Hurricane Center, Miami, for 2013 SKYWARN® Recognition Day. (Courtesy of WD4R)

How about –6 degrees Fahrenheit, with a wind chill factor of –26 . . . *and snowing?*

"We felt a little guilty when we gave them our report of *82 degrees and sunny* in South Florida," Ripoll said.

WX4NHC made contact with WFØEMA, at Federal Emergency Management Agency (FEMA) Headquarters, on 15 and 20 meters with Ted Okada, K4HNL, at the controls from FEMA.

"Ted had visited WX4NHC," Ripoll said, "and then installed the amateur radio station at FEMA Headquarters. This was the first HF contact between FEMA HQ and the NHC."

WX4NHC "appreciates all of the SKYWARN Spotters for their dedication and valuable surface reports," Ripoll said. "They are the eyes and ears for NWS and NHC."

He also thanked the VoIP Hurricane Net team operating from NWS Taunton "for sponsoring the net on EchoLink/IRLP."

Stations that contacted WX4NHC can request a QSL card via WD4R <http://www. QRZ.com/db/WD4R>. *(**VISIT:** The WD4R home page at <http://www.wd4r.com>.—KI6SN)*

Photo C. Robert McNeill, W4MBD, and Ed Pitts, K5OF, take their post in the Newport, North Carolina NWS conference room during SRD 2013. (Courtesy of KJ4JPE and John Cole)

Grassroots SKYWARN® Activity was Brisk in North Carolina

While WX4NHC is widely regarded as the hub of the wheel during events such as SKYWARN® Recognition Day, there is a beehive of activity at the grassroots level, as well. Here is a snapshot of SRD action centered on the National Weather Service office in Newport, North Carolina.— *KI6SN.*

SKYWARN® Recognition Day 2013 began at 2400 UTC at NWS Newport with the arrival of Ron Civils, KC4WVV, of Deep Run, North Carolina, who spent the wee-hours of Saturday making contacts on 40 meters.

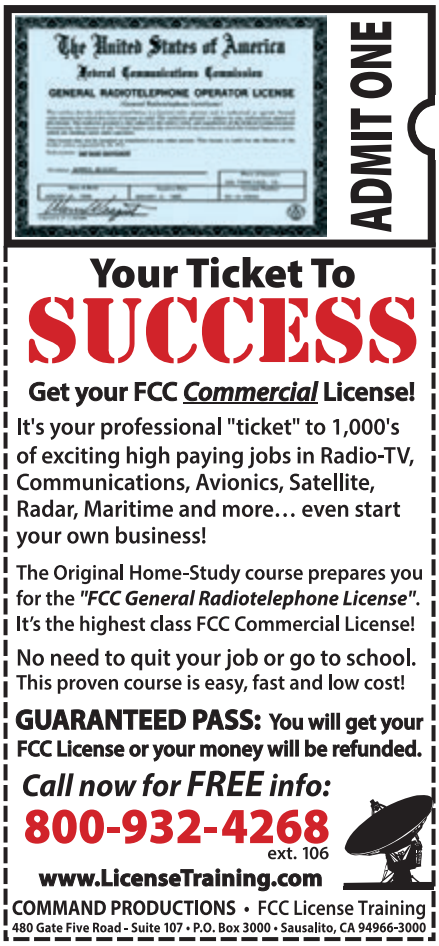

Photo D. William Moore, KK4SUF; David Kay, KJ4IGZ; Terry Passey, K4TRP; and Mike Miller, KK4VNH; oversaw operations from the Carteret County EmComm trailer during 2013 SRD. (Courtesy of KJ4JPE and John Cole)

Meanwhile, from her home in Swansboro, Janice Hopkins, KJ4JPE, made contacts as WX4MHX on the 2-meter K4GRW repeater using IRLP 9219. Later Saturday she carried on that activity from the NWS office in Newport. *(**MORE:** For a peek inside WX4MHX, visit <http://www.QRZ.com/db/WX4MHX>.—KI6SN)*

Terry Passey, K4TRP, made 10-meter contacts throughout Saturday using the Carteret County Amateur Radio EmComm trailer. Working inside NWS Newport was Ed Pitts, K5OF, using his Yaesu HF transceiver on 20 meters with the help of David Myers, KK4DEX, and Ed Myers, K4PEF's portable antenna trailer.

NWS Newport Chief Coordinating Meteorologist John Cole and Meteorologist Hal Austin, NC4HA, joined other staff members in welcoming more than thirty radio amateurs and their families, and giving tours of the facility.

Nineteen NWS contacts were made, along with many other SKYWARN amateurs (photos C and D).

*(**NOTE:** Information for this report was provided by Janice Hopkins, KJ4JPE, ARRL North Carolina Section Public Information Officer. She shared photography duties with NWS Newport's John Cole.—KI6SN)*

Florida Hams "Spoke Up" for Mount Dora Bicycle Festival

The Lake County (Florida) Amateur Radio Emergency Service provided radio communications to support the three-day Mount Dora Bicycle Festival sponsored by the Mount Dora Area Chamber of Commerce.

This was the 39th year for the annual event held each October.

"We had sunny weather for the three days with moderate temperatures and reasonable humidity so there were no reports of heat exhaustion," writes Ted Luebbers, K1AYZ, Lake County ARES® (Amateur Radio Emergency Service) Public Information Officer. "There were 703 bicycle riders registered this year, which was a slight increase over the past year" he said. "Most of the riders were from Florida, but there were some from various places in the United States. This is not a competitive race but a series of 15 separate bicycle tours through Lake County's countryside. The county has 1,400 named lakes and is considered to be Central Florida's hill country. This combination provides a scenic background and significant challenges for the riders. It keeps them coming back year after year."

The ARES group had 20 radio operators helping to keep track of the bicycle riders, K1AYZ reported. ARES also set up at rest areas, provided SAG wagons (vehicles that support cyclists) and radio-equipped mobile patrol vehicles (photos E and F).

"The ARES volunteers provided 255 man hours of service over the three days, Luebbers said. "All vehicles were directed by the N4FLA net control station, which had its mobile command trailer set up in the parking lot of the Mount Dora Chamber of Commerce.

Best wishes for the holidays and throughout the New Year.

"We used a 2-meter repeater provided by K4AUS on 147.390 MHz, and APRS (Automatic Packet Reporting System), with the 27-inch video monitor mounted in the trailer to keep tabs on the three SAG wagons. This video system can also be used to monitor weather conditions during any event."

Photo F. Strait Hollis, KT4YA, ARES® event coordinator for the MDBF, used his pick up as one of the mobile patrol vehicles and cyclist support wagons during the three-day festival. (Courtesy of K1AYZ)

A total of nine riders were transported to the Mount Dora staging area due to mechanical problems "or just getting tired out," K1AYZ said. "We had one report of *a rider down* with what appeared to be serious injuries . . . EMS was called and the fallen rider was transported by air to a local hospital for evaluation. Later we received a report that he was not seriously hurt and was released from the hospital."

Luebbers noted that the Lake Area Radio Association has been providing on-course radio communications for the Mount Dora Bicycle Festival for more than twenty years. LARA uses events such as this "to train its members to be ready to provide emergency radio communications for disaster situations such as hurricanes and tornadoes, which are not uncommon in this part of Florida. Members volunteer their time, radio equipment, and vehicles as a public service to the community," K1AYZ said.

*(**IN DEPTH:** For more information about amateur radio activity in Lake County, visit <http://www.n4fla.org> and <http://www.k4fc.org>.—KI6SN)*

Finis . . .

That's it for this month's *CQ* "Public Service" column. Remember, we're always on the lookout for the stories of your EmComm activities—whether it's from the scene of an emergency, training for one or your public relations efforts in supporting community activities. Please keep me on your mailing list via <KI6SN@cq-amateur-radio.com>. Every report helps us all to hone our EmComm skills. Let's hear from you or your organization soon!

73, Richard, KI6SN

kit-building

BY JOE EISENBERG,* KØNEB

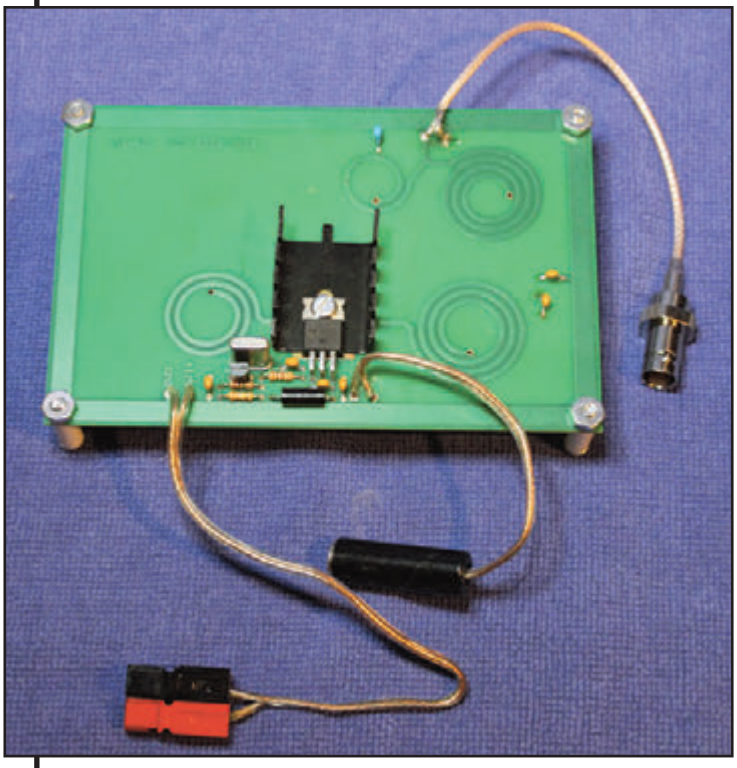
QRP Special

A Pair of QRP Quickies

When choosing a kit for building as a group or a first-time kit builder, the choices sometimes can be difficult. When building a kit as a group, the main limitations of time and space come into play. The need for a simple and quick-to-build kit becomes most important. Here is a kit that meets those requirements and puts out a great CW signal! The NS-40, designed by David Cripe, NMØS and sold by the Four States QRP Group is a great little 40-meter, crystal-controlled, 5-watt CW transmitter.

The NS-40 has a very small parts count, and no toroids to wind due to its unique design, making use of PC-board printed coils integrated into the PC-board design. Of course, the tradeoff with this design is that the board has to be a bit larger than would have been necessary if toroids had been used, but with no toroids to wind, you get a QSL-card-size board (more on that later). With just 14 parts to be soldered onto the board, this kit can be assembled by experienced builders in less than 30 minutes! This makes the NS-40 ideal for a beginning kit builder or for a group kit-building experience. I placed the resistors and capacitors first, followed by the other components.

*7133 Yosemite Drive, Lincoln, NE 68507
e-mail: <k0neb@cq-amateur-radio.com>



Completed NS-40 Kit. Only 14 parts make up this fun CW transmitter!

Unlike most kits, there aren't very many parts to sort, so the main cautions that apply are to be very careful in identifying the various capacitors and be sure that they are mounted in their correct locations. Watch your transistors to be sure they are mounted correctly as well, and be sure to use a little heat-sink grease on the final output transistor when mounting it to the board and its heatsink. The heatsink grease allows a more even and efficient flow of heat away from the transistor to the heatsink. The two transistors are the only polarized components in the kit, not including the wiring.

The PC board for the NS-40 is silkscreened and plated through and pre-tinned, making for quick assembly. What makes this PC board special is not only the built-in coils, but also the bottom of the board is printed in the form of a QSL card. Just fill in the particulars of your first contact, take a photo of it, and send that photo to your first contact! What a unique QSL card, and a great reminder of your very first QSO using this simple and fun kit.

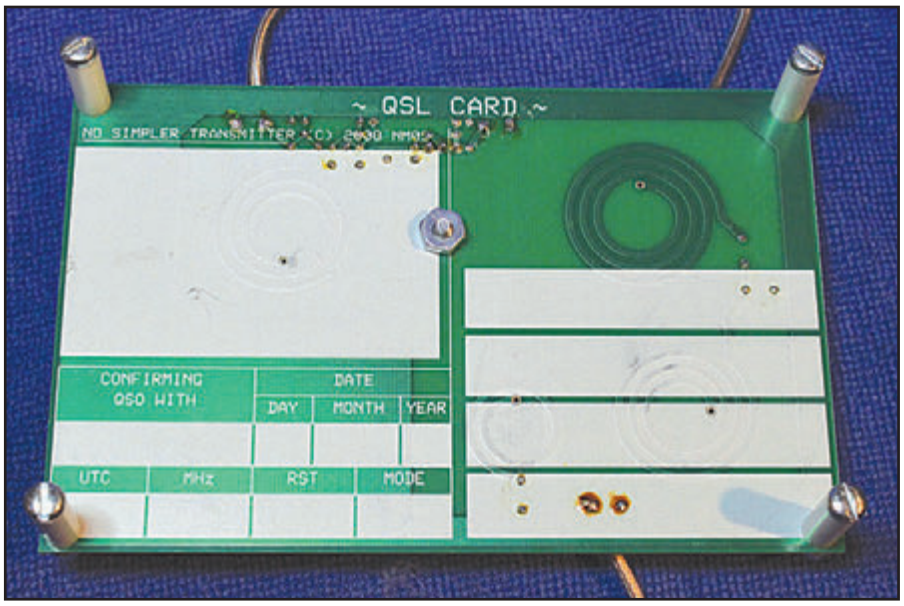
The NS-40 also does not come with any power cables or other connections. Those are easy to do yourself; just be sure that you double check your polarity, especially on the power leads. I advise building the pigtails before assembling the board so that the finishing step of making and attaching the cables goes easily and quickly. When I built my NS-40, I made three pigtails that connect to the board. The first pigtail I made is a connection to a Powerpole connector for 12 VDC. The next cable goes to an inline 1/8-inch jack for connection to either my straight key or keyer output. Finally, I used something I found in a flea market for the RF output. I had found a 4-foot RG-174 Teflon® coax cable that had a male SMA on one end and a female BNC on the other. I cut the female BNC end short to use for the RF output of the NS-40 and used the male SMA end with the longer cable for an RF DF kit connection to my HT. Scrounging this cable in hamfest flea markets, I got two cables for the price of one! Once the board is assembled, the legs for the PC board are attached and the transmitter is ready to go. The NS-40 puts out a full QRP "gallon" at 5 watts and requires no alignment at all.

The NS-40 can be used with either a manual T/R switch or a device such as the 4SQRP Magic Box automatic T/R switch. The NS-40 is on a fixed 40-meter frequency, mine being on 7.040, which is a known QRP watering hole. Of course, being hams, we like to improve on wonderful kits like the NS-40. A great little improvement for it is in the form of another 4SQRP kit, the SAVXO. The SAVXO was designed by Jim Kortge, K8IQY, and like the NS-40, it is sold by the Four States QRP Group.

The SAVXO connects to the NS-40 CW transmitter in place of the crystal and provides a stable 7–8-kHz tuning spread. In addition, the SAVXO itself can put out as much as 250 mw, making it usable as a QRPp transmitter as well! There are

two build options in the manual, one for use as a VXO in most oscillator circuits and the other specifically to drive the 5-watt MOSFET final in the NS-40, which requires more drive. Be sure to carefully follow the part selection for your chosen options, as the components needed for either option are both provided in the kit. If you decide to use the SAVXO as a standalone QRPp transmitter, be sure to download the additional information on the web site for the SAVXO.

Building the SAVXO is pretty straightforward once you have selected your option. Be sure to only install the parts called for during the initial construction before adding your chosen option components. Also, be sure to follow the directions carefully when installing the crystals. A paper insulator needs to be made for each crystal before it is installed in order to prevent shorting it



Bottom of the NS-40a kit featuring the blank QSL card to be filled out with your first QSO.

CommRadio CR-1

The **CommRadio CR-1** is a true SDR, but does *not* require a computer. Enjoy the benefits and performance of state-of-the-art SDR, but in a conventional radio package. The CR-1 SDR is independent of a host PC, using embedded digital signal processing technology that provides a degree of portability and performance previously unavailable to the radio enthusiast. Coverage includes: 500 kHz-30 MHz, 64-260 MHz and 437-468 MHz in AM, SSB, CW, WBFM, NBFM modes. (150-500 kHz with reduced performance). The incredible performance is combined with exceptional portability and ease of use. The radio may be powered via USB or 6-18 VDC input. Enjoy *top-shelf* American technology in a compact, metal case measuring 5.64 x 2.43 x 6.10" 1.8 lbs.

Visit **www.universal-radio.com** for details!

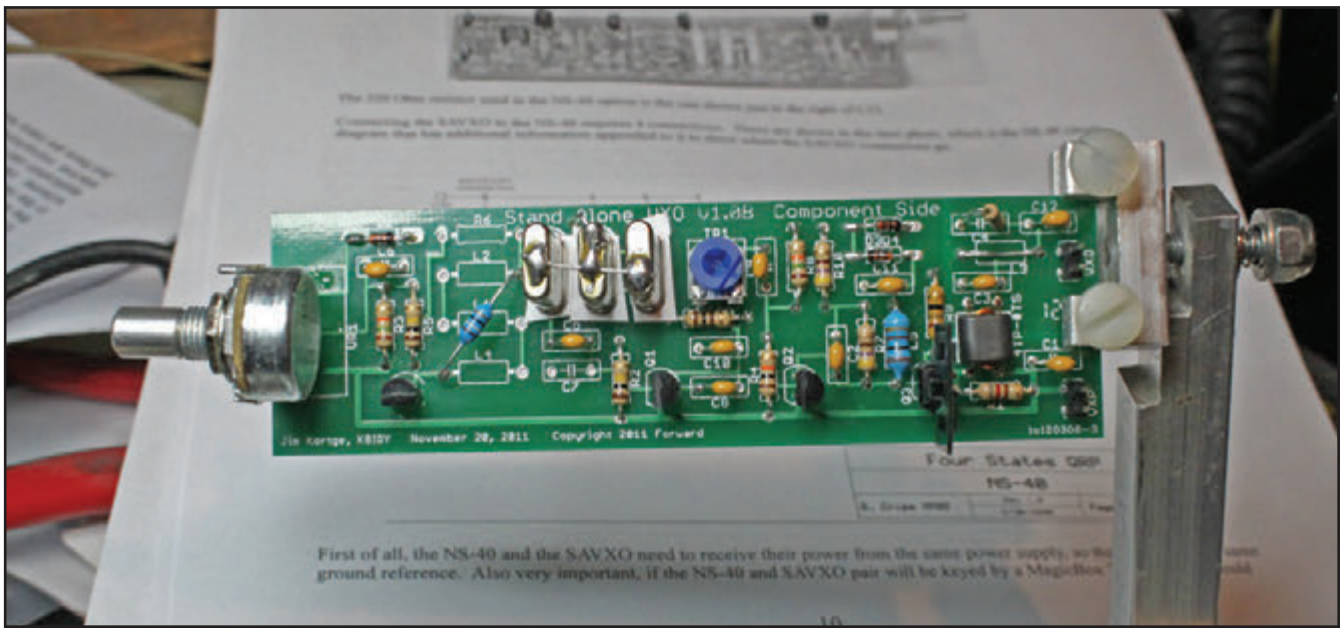
SAVXO board ready for assembly.



Completed SAVXO board with NS-40 option 2 ready to be connected to the NS-40.

what's new

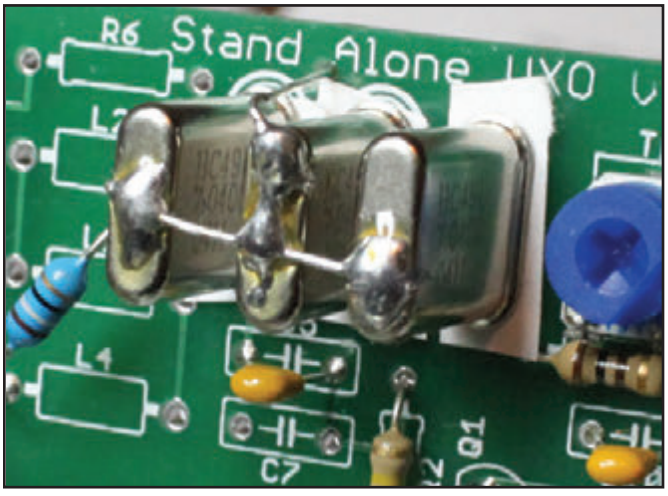
N3FJP Software Amateur Contact Log 4.5

Version 4.5 of N3FJP's Amateur Contact Log program is now available. Features include an update to accommodate Version 2.0 of the ARRL's TQSL software for Logbook of the World, support for the Wireless Institute of Australia's awards program, and a bug fix for interfacing with the Yaesu FT-847 transceiver. Upgrades are free to registered users. You'll find AC Log 4.5 at <http://www.n3fjp.com/aclog.html>; Steps to upgrading are at <http://www.n3fjp.com/upgradestepsaclog.html>.

RF Micro Devices 1.2-GHz Power Doubler Amplifier

Designed primarily for cable TV operators trying to meet new DOCSIS 3.1 cable specifications, the new RFCM3316 Gallium Nitride (GaN) power doubler amplifier from RF Micro Devices (RFMD) may be of interest to amateurs as well. It operates from 40 MHz to 1.2 GHz and has 20% less current consumption than equivalent Gallium Arsenide devices. The company also notes its small footprint as well as ruggedness and excellent linearity. Full-scale production is expected to begin in early 2014. For more information, visit <http://www.rfmd.com/>.

Note: *"What's New" is not a product review and does not constitute a product endorsement by CQ. Information is primarily provided by manufacturers/vendors and has not necessarily been independently verified. The purpose of "What's New" is to inform readers about new products in the marketplace. We encourage you to do additional research on products of interest to you.*



Close-up of the three crystals in the SAVXO with case grounding wires attached.

during installation. There is also a small binocular-type toroid, but it is relatively easy to deal with. Just pay close attention to the number of windings needed for your chosen option. Once completed, a frequency counter or a good receiver is very useful to determine if the SAVXO is operating correctly. Expect to spend around two hours or so putting this kit together.

The NS-40 sells for $32 including shipping in the USA and is sold by the Four State QRP Group at <http://www.4sqrp.com>. The SAVXO is $25, also including USA shipping from 4SQRP.

This probably would be a great time to mention the upcoming Ozarkcon QRP Convention in Branson, Missouri on April 4–5, 2014. This fun weekend features lots of great QRP forums as well as a live hands-on kit building experience! With lots of family things to do in Branson, Ozarkcon is a great family weekend trip. Ozarkcon is at <http://www.ozarkcon.com>. See you in Branson! Until next time . . .

73 de Joe, KØNEB

What You've Told Us…

Our November survey asked about your ham radio-related holiday wish list. Just over half of you who responded either hoped or expected to receive at least one ham-related gift. (Did you get it?) On the other hand, when we asked if you were planning to give *someone else* a ham-related gift, only 9% said yes, 85% said no and 6% weren't sure.

If you could receive only one ham-related gift… 29% of you said you hoped it would be a station accessory, followed by an HF transceiver at 24%, and HF antenna (18%) and a tower to put it on (10%). If you could get *two* ham gifts, then nearly one in five of you each hoped the second one would be either a station accessory or a new/renewed subscription to *CQ* or one of its sister publications (Thanks!). Those were followed by an HF transceiver (15%) and an HF antenna (12%). All of the other options were "in the noise."

Among those of you hoping to get ham equipment of some sort, 56% of you were looking for new commercially-built gear and 32% wanted a new kit to build; and just a handful of you were looking either for parts from which to build something yourself or used gear to operate, modify or repair.

Finally, we asked what broad goal you'd like to accomplish with whatever new gear you got. Forty-nine percent said "enhance my station's capabilities for bands/modes I already use," followed by 19% who looked forward to making operation of their stations easier or more flexible and 13% who wanted to enhance their stations by adding new bands or modes.

This month's free subscription winner is Walt Smith, K1QS, of Naples, Maine.

Reader Survey February 2014

We'd like to know more about you … and especially what's important to you in ham radio and how we at *CQ* can help serve you better. There are two ways to respond to this survey:

*** Respond online** at <www.surveymonkey.com/s/CQFeb14> [From the digital edition, just click on the link].

- OR -

*** Cut out or photocopy** this page

*** Circle the numbers** that correspond to your answers

*** Mail your completed survey to:** November Reader Survey, CQ magazine, 25 Newbridge Rd., Hicksville, NY 11801.

We will continue to select one respondent to each survey to receive a free one-year subscription (or extension) to *CQ*. This month, as we expand our coverage to include more than just ham radio, we'd like to know a little more about your broad radio interests.

1. Which of the following hobby radio activities do you currently enjoy?

Amateur radio / HF 1
Amateur radio / VHF/UHF 2
Broadcast band DXing 3
Broadcast history 4
Personal 2-way radio (e.g., CB, FRS, MURS) 5
Radio technology (including building/restoring equipment) 6
Shortwave listening 7
VHF/UHF scanning/monitoring 8
Other (please specify) 9

2. Which of the following activities provided your *introduction* to the radio hobby?

Amateur radio / HF 10
Amateur radio / VHF/UHF 11
Broadcast band DXing 12
Broadcast history 13
Personal 2-way radio (e.g., CB, FRS, MURS) 14
Radio technology (including building/restoring equipment) 15
Shortwave listening 16
VHF/UHF scanning/monitoring 17
Other (please specify) 18

3. Before this month, to which CQ publication(s) did you subscribe? (Select all that apply)

CQ Amateur Radio 19
CQ VHF 20
Popular Communications 21
WorldRadio Online 22
None 23

4. What is your primary choice of device for reading a digital magazine?

Desktop computer 24
Laptop computer 25
Tablet (e.g. iPad) 26
E-reader (e.g., Kindle Fire) 27
Smartphone 28
None 29

Thank you for your responses. We'll be back with more questions in upcoming issues.

How to Create an Inexpensive Software-Defined Receiver

It has been a while since we got into some deep digital, but with the new year we are changing that. This month we'll see how to create a very cheap (less than $15) software defined receiver with a frequency range of about 50 MHz to 2.2 GHz. What would you do with such a receiver?

The business end of this receiver is a USB TV reception dongle used to receive digital video in much of the world (but not the USA and Canada). In normal use, the receiver just down-converts the received signal and delivers I and Q data to the computer for TV decoding. (I and Q are the In-phase and Quadrature [90° phase] amplitude-modulated sinusoidal components of an angle-modulated signal. Reducing an angle-modulated signal [such as FM or PSK] to two AM signals greatly simplifies the post-processing of the signal in the digital realm.)

I found several suppliers for these receivers on eBay and ended up buying one from Hong Kong for $12.97 including shipping. It did take almost three weeks for it to arrive, but I was in no particular hurry. You can buy one from a USA-based seller for a somewhat higher price if time is a consideration.

What you want to buy is a DVB-T (Digital Video Broadcasting – Terrestrial) USB dongle that uses the Realtek 2832U control chip and the Elonics E4000 tuner chip. There are dongles that use other tuner chips, such as the FC0013 (22–1100 MHz) or the R820T (24–1766 MHz), and these will work but with a different tuning range. The E4000 has a specified tuning range of 64 to 1700 MHz, but it can be operated outside that range if we can accept less-than-optimal LNA (low noise amplifier) performance. Note that there is a gap in frequency coverage on the E400 from about 1100 to 1250 MHz.

To control this receiver I used a program called SDR# (pronounced "SDR Sharp"; see <http://sdrsharp.com/>). For me, the attraction of this particular program is that it runs under Windows®. If you have a Mac or Linux machine, you have other options such as Gqrx <http://gqrx.dk/>, or search the Internet for several other choices. SDR# can decode several common modes (SSB, FM, AM, and CW) using your computer's sound card and offers a familiar waterfall display.

If you find the frequency range of 50 MHz to 2.2 GHz somewhat limiting—I'm thinking of the HF bands here—you can buy an upconverter to shift the received frequencies up to where we can use the SDR to receive them. NooElec <http://www.nooelec.com> sells its Ham It Up v1.2 upconverter for $43, and it shifts received signals up in frequency by 125 MHz to allow signals from almost DC to about 65 MHz to be received. I'd wanted to buy one to try it out, but that wasn't in the cards; however, a review of the documentation on its web site has convinced me that it is easy to install and use. If you have or buy one, let me know what you find.

Of course, a receiver is only as good as its antenna. Outside the specified frequency range of 64 to 1700 MHz the receiver loses some of its sensitivity, making a good antenna that much more important. My SDR dongle came with an antenna, but for all but the most powerful broadcast-band stations it was useless. Its only real value is the connector and coaxial cable, on which I mounted a BNC connector, simplifying connections to my various antennas for testing. (See fig. 1.)

My outdoor ground-plane antennas for 2 meters and 70 cm worked well enough for the local repeaters, as did my loop Yagi on 23 cm. I was also able to use the 2-meter antenna to pick up some nearby aircraft on the local FAA approach frequency, as well as the town police and fire departments.

For the more adventurous among us, consider a low-noise preamplifier for the band(s) in question from Down East Microwave (http://www.downeastmicrowave.com/) or the PR-2 broadband

Fig. 1. The USB Dongle and unmodified antenna. The dime is there for scale. This particular unit receives from 52 to 2202 MHz, with a gap between 1102 and 12324 MHz. The antenna is only useful for the end connector that mates to the Dongle.

*P.O. Box 114, Park Ridge, NJ 07656
e-mail: <n2irz@cq-amateur-radio.com>

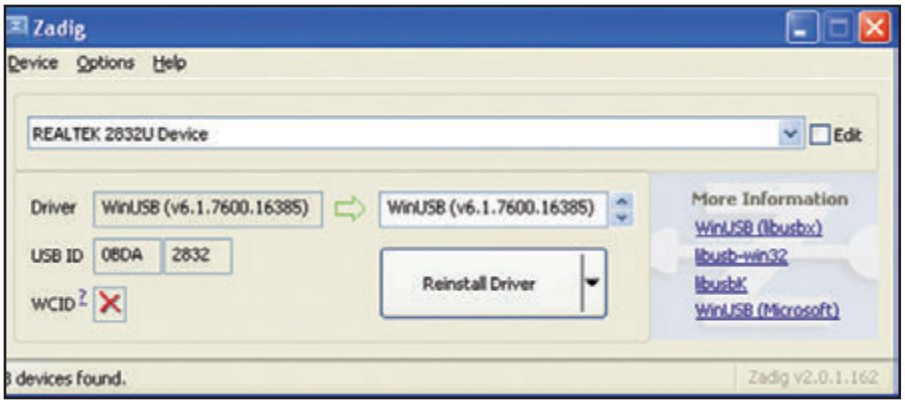

Fig. 2. The Zadig driver installer for Windows® XP. The WinUSB driver is absolutely essential to getting SDR# to recognize the dongle, and for me was by far the most difficult challenge in getting everything to work. Just make sure you install the driver for the USB Dongle and not for some other device! Check the USB ID as explained in the text to make sure.

preamp sold by Ramsey Electronics (http://www.ramseyelectronics.com/).

Hardware

The first step in making all this happen is to buy the DVB-T USB dongle. As I stated before, you want one with the Realtek RTL2832U control chip. The preferred tuner is the Elonics E4000, but any tuner will work, just with a different frequency range. On eBay, I did find several listings that mention the E4000, but upon careful reading I found the device they were offering had a different tuner chip in it. Some were claiming that this or that chip was an "Upgrade to the E4000," but don't believe it. Do your research, and buyer beware.

Once the unit arrives, the first step is to throw out the software disk that comes with it (although mine just came with a web address). If you happen to install the software and driver, I am told you'll have a devil of a time getting rid of it.

Software Installation

Visit the SDR# downloads page at <http://sdrsharp.com/index.php/downloads> and then find and download the file "sdr-install.zip." Unzip it to a directory in My Documents, and run the file "install.bat." This will automatically go to various websites, download the necessary files, and place them into a directory named "sdrsharp." You can go and download things manually, following the instructions in the *SDR# Quick Start manual*, but this batch file really does work nicely and eases installation considerably.

Note that by "installing" all these files to a directory, SDR# is not really "installed," but merely copied. This means that the Windows® registry is not touched, and you can move the entire installation from one computer to another simply by copying the files.

Zadig Driver

Once you have the USB Dongle, connect it to a handy USB port on your computer. With some luck, Windows® will recognize the device and install some kind of driver; allow it to search the Internet if it asks. It doesn't really matter which driver it installs, since we're going to replace it, but having a driver makes the next step easier. It took my computer a few tries before it installed a driver (and even then it took several minutes), so be patient and persistent.

Once a driver installs, you will want to *replace it with the Zadig driver.* The version of Zadig that is installed by the batch file is an older version that should work fine in Windows® XP or later, but if you download it yourself from the Zadig website <http://zadig.akeo.ie/> as I did, make sure you get the correct file for your version of Windows®.

This is a summary of the instructions that can be found at <http://rtlsdr.org/softwarewindows>, along with some of my own observations. Run Zadig.exe and, after you allow the program to run, you'll see the window shown in fig. 2. Select "Options" and check "List all devices." Then click on the devices list and pick the entry that says "Bulk-In, Interface (Interface 0)." If your list doesn't have this entry, don't panic: You instead may see an entry such as "RTL 2832" or something very similar. Mine said "REALTEK 2832U DEVICE" as shown in the image. To be certain, check the USB ID numbers against the hardware list at <http://

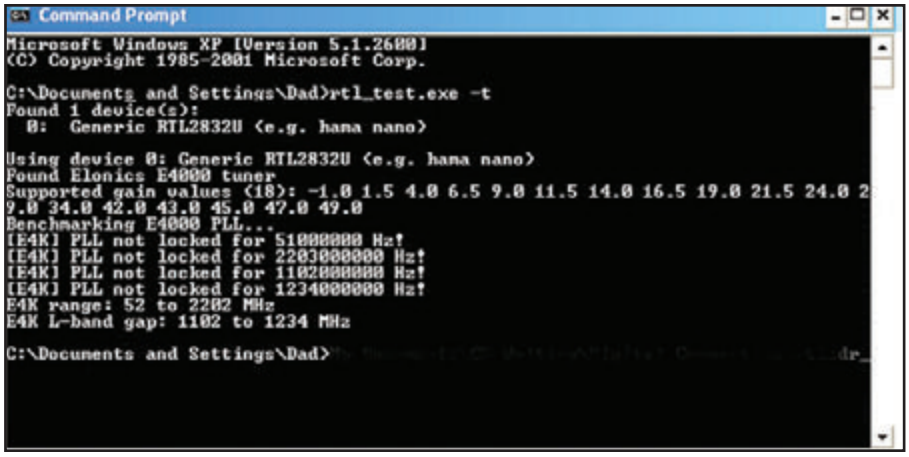

Fig. 3. Running rtl_test.exe –t in a Command prompt window verified my device was working properly, as well as telling me the expected bandwidth and gap, and verifying that I have a real E4000 tuner installed and not a less-capable "equivalent."

rtlsdr.org/hardware-usb>, and if yours are listed, you are on the correct entry. WARNING: Being on the *incorrect* entry can cause a problem. You are replacing the original driver, so whatever is using that driver (such as a keyboard) probably will stop working.

OK, so whatever the device name is, if you've verified the USB ID is on the hardware list, you should make sure you're going to install the *WinUSB* driver (and not the *libusb* driver). Go ahead and click the "Install driver" (or Reinstall Driver—the button text changes depending on what's in there) button. Installation should take about a minute.

Now that we've installed the driver, start SDR# by double-clicking the SDRSharp.exe file. (You might want to right-click it, and pick "Send to ... Desktop" to create a shortcut). You should see a display something like fig. 3.

Still a Few Bugs in the System

In theory, if you select the "RTL-SDR / USB" device at the upper left and set everything correctly (Select Wideband FM, connect a decent antenna, tune to a big local FM station, and click "Play") you'll be receiving signals. Ah, but sometimes reality gets in the way of theory. While most users report a completely problem-free installation, I was one of the lucky ones who had to spend a day fooling with the driver.

Oh, it was installed, but SDR# alternately didn't recognize the driver and the device, sometimes complaining the "RTL-SDR/USB is either not connected or its driver is not working properly," and other times complaining "RTL-SDR

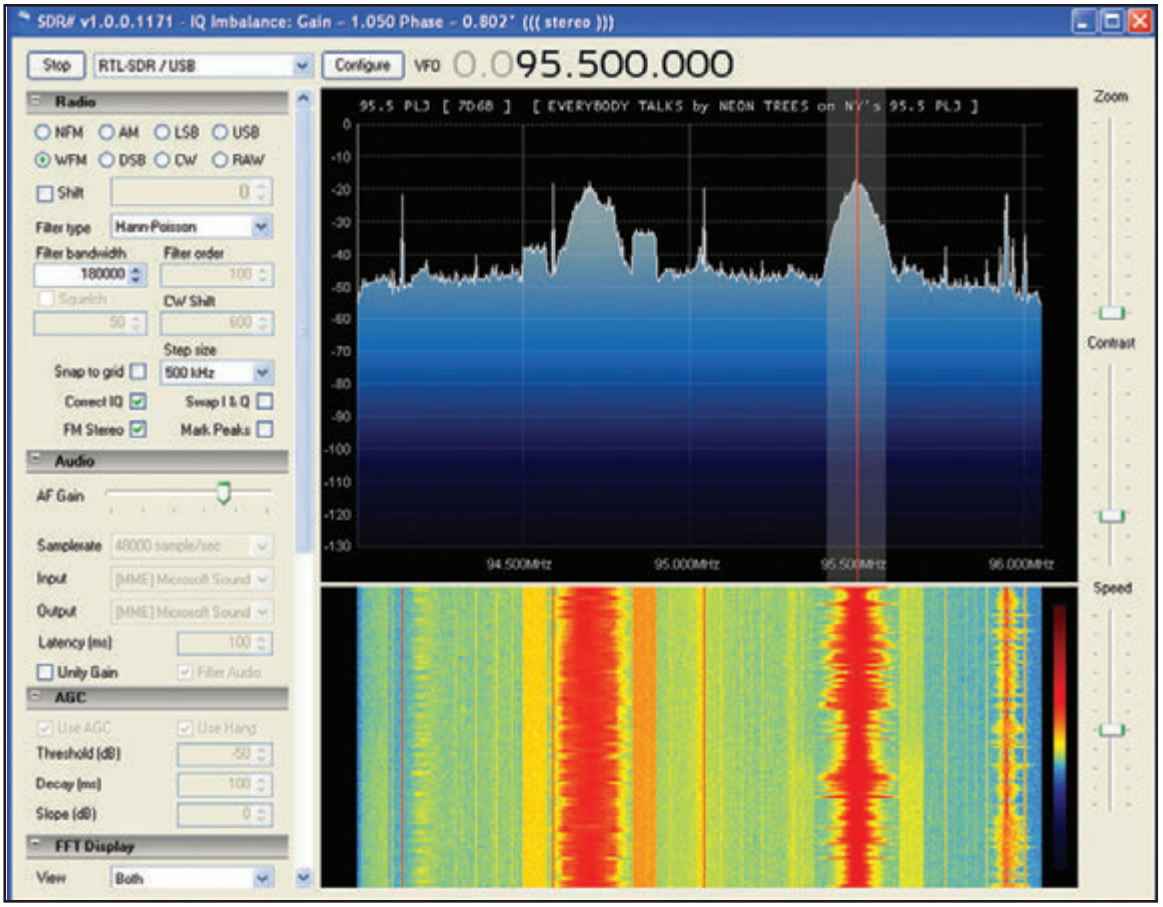

Fig. 4. SDR# tuned to New York FM station WPLJ, 95.5 MHz. Note the station's crawler text (along the top of the spectrum window). The station at 94.7 MHz has clearly visible HD Radio sidebands. I have SDR# configured for Wideband FM, with a filter bandwidth of 180 kHz, FM Stereo decoding enabled, and SDR#'s exclusive I/Q correction system, which helps correct any I/Q imbalances, also enabled.

The *Navigator* Sound Card Modem - New at Timewave! *Now Shipping!*

- Single USB connection to computer
- USB Sound Card built-in
- USB Powered
- Universal Rig Control built-in - logic level +/-, CI-V, CAT, & RS-232!
- Software Configuration - *No jumpers*!
- FSK Controller for Precise RTTY
- K1EL Paddle & Keyboard Precise CW
- Separate COM ports for PTT, FSK, CW, CI-V & RS-232 - *no port splitters*!

The *Navigator* is a complete USB sound card modem featuring a proven USB audio sound card chip, six FTDI USB serial COM ports, a K1EL WinKeyer, True FSK and rig control connections for every radio. It has a built-in USB sound card with isolated audio I/O to your radio to prevent ground loops. A second audio input lets you use both receivers in a dual receiver radio. The logic level and RS-232 rig control ports support your Icom CI-V, Yaesu CAT, Kenwood and other radios. Front panel controls set both RX audio levels, TX audio ouput level, audio monitor level and the CW speed. There are no internal configuration jumpers - just conveniently set the software-controlled configuration settings from your PC.

USB device not found." I reinstalled the Zadig driver several times, also trying the "libusbK" driver, rebooting each time—maybe 25 times over the course of a whole day. In between tries, I was scouring the web looking for help. I found the USB Dongle itself was working normally by running "rtl_test.exe" with the "-t" option (found within the ZIP file at <http://bit.ly/HRswcR>); see fig. 3. I did manage to actually crash my PC once, and also had to reinstall SDR# twice. It would work a little sometimes, and not at all other times, including one time with no reception at all.

Ultimately, I cannot really say what happened to make it work, but it did actually work—and that's when I found out how important a decent antenna is. Even when it was working well, sometimes it would stop tuning, or stop receiving any signals, and this was usually cured by clicking "Stop" and then "Play" again, but sometimes I had to close and restart the software for it to come back. I suspect that a flaky USB connector might have had some effect on this.

I also forgot to mind the band edges, trying to tune in WABC-AM on 770 kHz, a very powerful local AM broadcaster. I noticed that one pretty quickly. I did manage to get most of the commercial FM band, where the HD Radio subcarriers are clearly visible (fig. 4), and SDR# even showed the low-speed text crawler that some stations have. I then monitored a local 2-meter repeater and found that the default 10-kHz filter bandwidth for Narrow FM was way too wide: Setting this around 5 kHz dramatically improved the received audio.

Fun with the Receiver

I've been having fun playing with this receiver. The software is easy to learn, although I did refer to the Quick Start Guide a few times for an explanation of some of the settings. The receiver itself is as small as a postage stamp, and almost as light, making it perfect for travel, a spare receiver for field work, and handy to have for emergencies: During superstorm Sandy last year, broadcast radio was about the only source for news and information, since phones, power, and internet were out almost everywhere.

3D Printers

Since my pair of columns on 3D Printers went out (October and December 2013 issues), the Oak Ridge National Laboratory, the Department of Energy's Advanced Manufacturing Office, America Makes (formerly NAMII), MakerBot, TNFIRST, 3D Systems, and MakerGear decided to make a 3D printer available to thousands of high schools around the world that have a FIRST Robotics Team <http://www.usfirst.org/>. They are starting with 400 printers this year and expanding it to most teams next year. Although we're not quite at the point where 3D printers are able to produce almost anything, we're not too far from that either.

A colleague compared the current state of the art in 3D printers to the state of the art in home computer printers in 1990. Back then, I had a 9-pin dot-matrix printer that was slow, noisy, jammed often, and used special paper with tractor feed holes along the sides. How primitive those were in comparison to what we can get today! In just a few years, 3D printers that can produce real and useful items of many materials will be available at Walmart for $29, but surely the "ink" will cost twice that! As for me, *I just can't wait.*

That's all this month, and I'll be back in this spot for the April edition. In the meantime, give the USB receiver in this month's column a try, and write to let me know how you made out, especially with that driver installation.

Until then . . . 73 de Don, N2IRZ

learning curve

BY RON OCHU,* KOØZ

Repeaters

In a previous edition of this column I wrote that a repeater serves as a club cornerstone. Many of us use repeaters and we want to "pay our fair share" by supporting the club sponsoring the repeater. Repeaters serve a vital ham radio function, for they allow us to communicate with each other with lower power radios and vertical antennas over a greater distance than would be possible without them (fig. 1). I think most hams are familiar with a repeater and have even used one, but how many hams have actually seen a repeater, much less be able to identify its specific parts?

Location, Location, Location!

Well, if you wanted to learn more about repeaters then today is your lucky day; read on, dear reader! I would like to thank Skip Riba, WS9V, for taking me on a tour of his UHF repeater (photo A). Skip's repeater is located on a 480-foot tower just northwest of Litchfield, Illinois (photo B). This is farmland and prairie country. The land around here is flat for miles. When I moved here about two years ago, I asked Skip if he knew of any high spots in the county and his response was "If I did know of any, my repeater would be on it!" Hence, his repeater is located on a former Western Union microwave relay site. From this location, Skip's repeater has consistently good coverage throughout a 60-mile diameter circle and fairly good coverage over a 100-mile diameter! Add icing to the cake, and Skip linked his repeater with ones in five nearby cities (fig. 2), giving hams in the area seamless FM coverage throughout most of central and southern Illinois!

In the VHF/UHF world height is everything. That's why out in the mountain states, repeaters are located on mountain peaks. Here in the Midwest, water towers, tall buildings, or former commercial microwave relay sites are sought after for their height above average terrain (HAAT). Unfortunately, these sites are becoming increasingly hard to find because of tightened security and commercial competition. Cell-phone companies want these sites, too, and they are willing to pay top dollar to rent antenna space, which is putting these sites well beyond the budgets of most clubs. Sometimes stressing the public-service aspect of amateur radio is one way to help secure antenna space at reduced cost on municipal government water towers or tall hospital buildings. The WS9V repeater system is directly linked

*e-mail: <ko0z@cq-amateur-radio.com>

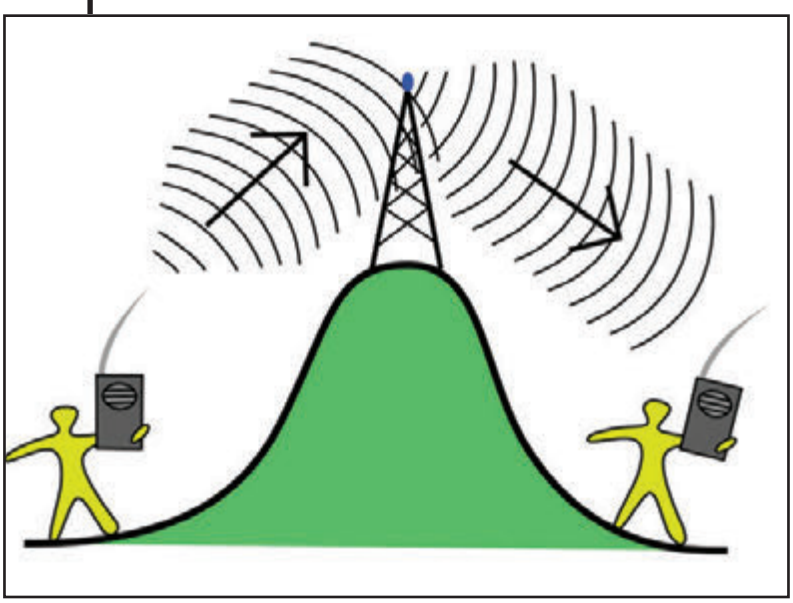

Fig. 1. Repeaters extend the range for HTs and mobile rigs. (Figure by Mouagip, via Wikimedia Commons)

Photo A. Skip Riba, WS9V, standing next to the mighty 444.250 linked repeater serving central and southern Illinois and providing a direct link to the St. Louis National Weather Service office. (Photos by the author)

Photo B. The WS9V repeater is at a former commercial microwave relay site near Litchfield, IL.

Photo C. An example of a commercial VHF 4-bay (folded-dipole configuration) repeater antenna.

back to the National Weather Service St. Louis office, and it provides an invaluable SKYWARN® link for that office's eastern counties watch area.

Let's Take a Look Under the Hood!

Once a high spot for the repeater is secured, the first thing to think about is putting up a durable commercial antenna. These antennas can withstand the harsh environment of a repeater site. It's no fun to replace a repeater antenna that weighs 24 lbs and is 20 feet in length, especially so at the WS9V/R site, which requires climbing a 480-foot tower clear to the top. Another feature of a commercially built antenna (photo C) is its radiation pattern. Besides being omnidirectional, it also can focus most of its energy out toward the horizon, which maximizes the gain (ability to transmit and to receive signals over greater distances). However, these antennas are not inexpensive. With shipping, they can cost nearly $1000, and many site owners require that you hire professional installers to put them up.

Minimizing Feedline Losses

Having a high-gain antenna is a must for a repeater site, but it is also vitally important to minimize feedline losses. This means that hardline coax is utilized to carry the signals between the antenna and the repeater (photo D). At WS9V/R, Skip uses Andrews 1-1/4-inch hardline to minimize signal losses. Again, this is a significant expense. New Andrew 1-1/4-inch hardline costs over $10 a foot. Connectors for each end are well over a $100 each.

Why use such large diameter hardline? The published specs for $1^1/4$-inch hardline at 450 MHz show a predicted loss of .55 dB per 100 feet. Now compare that figure with that of high-quality LMR 400 low-loss coax, which at 450 MHz has a rated loss figure of 2.7 dB per 100 feet. With a 500-foot run to the antenna, the hardline has approximately 3 dB of loss, or about half the power that you started with. In the same situation, the LMR 400 would suffer losses of 13.5 dB! Keep in mind that every 3 dB either adds to the power by a factor of 2 (gain) or decreases it by one-half (loss). Thus, it's clear why you want to minimize feedline loss in this situation. Adding the connectors introduces some slight signal loss as well; therefore, good-quality "N" connectors are a must.

Are We There Yet?

Okay, we now have the RF from the antenna going down the tower leg and almost into the shack. Prudence and experience teach us to make sure that the hardline and the antenna are at a DC ground. Photo E shows a grounding strap from the hardline to the tower leg, which in turn goes to an earth grounding rod. Skip has his hardline grounded near the

antenna and halfway down the tower as well as at the bottom of the tower, and all of that goes to a common-point ground on a grounded copper plate inside the building. A quick-acting gas-filled cartridge lightning protector such as a Polyphaser is also part of the grounding system. Now we are ready to introduce the antenna system to the repeater system!

What Else Makes Up a Repeater?

A repeater typically consists of five major components in addition to the antenna and feedline (fig. 3 and photo F): a receiver, a duplexer, a controller, a transmitter/amplifier, and a heavy-duty power supply. Let's take a look at each of these elements and how they work together.

For starters, most repeaters listen on one frequency and transmit on another. The WS9V repeater system listens on 449.250 MHz and transmits on 444.250 MHz. Consequently, when I program my mobile FM transceiver or my HT, I need to include the proper "offset." By that I mean that when I dial in 444.250 MHz my radio is *listening* on that frequency, but when I press the push-to-talk (PTT) switch, my radio now trans-

mits 5 MHz higher, at 449.250 MHz, which, not coincidentally, is the frequency on which Skip's repeater is listening! (A 5-MHz "split" is standard on 70 centimeters, or 440 MHz.)

By convention, hams name a repeater by its transmit frequency (your receive frequency). For example, "I am going to QSY to the 444.250 repeater." When I am in the St. Charles area, I use the 146.67-MHz WBØHSI repeater. That repeater transmits on 146.670 MHz and listens on 146.070 MHz. Notice that these frequencies are only 600 kHz apart, the standard for the smaller 2-meter band. It is important to program your radio with the proper offset. Current FM transceivers and HTs have automatic offset switching for each ham radio FM band.

Duplexer

Duplex means to transmit on one frequency and to receive on another. Most repeaters are "in-band," which means transmit and receive frequencies are within the same band, such as the WS9V repeater, which is on 70 cm. A duplexer allows a repeater to use only one antenna and one feedline, even though it is receiving and transmitting simultaneously on the same band. The other option is to have a separate transmit antenna with feedline along with a

Photo E. A good ground is a must for lightning protection and lowering noise levels.

Photo F. The front side of the rack-mounted WS9V repeater system. On the top is the 449.250-MHz receiver and below that are the ACC RC-96 controller, the 444.250 MHz transmitter, the 70-cm BpBr duplexers, the TPL 180 watt amplifier, and the Astron 70 amp 13.8-VDC power supply. Not pictured is the battery back-up in case of commercial power failure.

separate receive antenna with its own feedline. If both antennas are going to be at the same site, then they need to be physically separated from each other—either vertically or horizontally—by a calculated wavelength distance, which greatly complicates the repeater's mechanical arrangement (not to mention the cost). Duplexers, on the other hand, make a repeater installation a whole lot simpler.

The WS9V repeater uses a four-cavity Wacom BpBr duplexer (photo G). Bp means *band pass* and Br means *band reject*. In essence, two cavities are connected to the repeater's transmitter/amplifier and they allow only the transmitter frequency of 444.250 MHz to pass on out to the repeater antenna. The other set of two cavities rejects all other frequencies and allows only signals on 449.250 MHz to pass through to the repeater receiver. It does this simultaneously using only one antenna and hardline for both transmit and receive! Like everything else, duplexers are not inexpensive. A vital part of a duplexer is to have low-loss coax cable connecting it to the receiver and the transmitter. This prevents unwanted noise and interference from getting into the system.

Receiver

Skip's repeater uses an old Spectrum Communications UHF receiver. Although this receiver is old, it still has high sensitivity and selectivity. After all these years, it keeps on working 24 hours a day and seven days a week. The audio from the receiver is now fed to the repeater controller through low-loss coax.

The Repeater Controller

The controller is the "brains" behind a repeater. It is a computer circuit that controls a number of functions such as when to come on or off. It has a built-in timer that is set to limit the amount of time the repeater transmits before "timing out," or automatically shutting down the transmitter. Most repeaters try to keep a person from being "long-winded" by timing out before three minutes have elapsed since the repeater was first keyed-up. That's why it is proper repeater etiquette to keep your transmissions short and to let the repeater reset its timer. You'll usually know when the timer is reset by the courtesy beep.

If the repeater is set up with tone access, the controller takes care of that function as well. Many repeater owners require the use of a CTCSS (Continuous Tone Coded Squelch System) tone—also frequently referred to by its Motorola trademark of PL, or Private Line—to access the repeater (WS9V/R uses a CTCSS tone of 103.5 Hz). This is a subaudible tone that is transmitted on your RF carrier, which tells a repeater's receiver to allow your signal to be retransmitted. This system goes a long way toward reducing a lot of noise and interference during band openings.

The controller also has a carrier operated relay which senses an incoming signal and then sets all of the programmed repeater control functions into play. There is also a port for a phone line and a command receiver (222 MHz or higher) for control operator functions such as disabling the repeater, putting it into "weather mode," etc. Finally, the controller identifies the repeater with a voice or CW callsign identification. It now takes the receiver audio and passes it on to the transmitter/amplifier combination.

Transmitter/Amplifier

Once the controller sends the audio to the transmitter, it is now able to take the received audio and pass it on to the repeater's amplifier. The WS9V re-

The #1 Line of Autotuners!

LDG ELECTRONICS

Your Favorite Dealer has these tuners in stock NOW!
Don't Miss Out - Call or visit them TODAY!

NEW! RT-100

A Technological Breakthrough in Remote Tuning!

Coax in / coax out tuner designed to be placed near the feedpoint of the antenna. Place the RT-100 near the feedpoint and virtually eliminate all feed line loss due to SWR. DC powered over the coax, so add your own DC injection circuit or use the LDG RC-100 to power and control the tuner from your shack. The RC-100 will provide DC power over the coax as well as control for Auto mode, Lock, and Tune.

Suggested Price $199.99 ***Optional RC-100 $49.99***

IT-100

Manual or automatic tunes. Control from either its own button or the Tune button on your IC-7000 or other Icom rigs. AH3 or AH-4 compatible.

Suggested Price $179.99

AT-600ProII

Two-position antenna switch, 2,000 memories that store tuning parameters for almost instantaneous memory recall whenever you transmit on or near a frequency you've used before. Includes six-foot DC power cable.

Suggested Price $369.99

Optional M-600 external analog meter $129.99

AT-1000ProII

1KW tuner features: 5 to 1,000 Watts PEP; RF Sensing; Auto and Semi Tuning Modes; 1.8 to 54 MHz range; 6 to 800 ohm range (15 to 150 on 6M); simplified operation; Two position antenna switch, 2,000 memories.

Suggested Price $539.99

Optional M-1000 external analog meter $129.99

peater uses a Spectrum transmitter and its RF output feeds a TPL UHF amplifier which amplifies the transmitter's RF to 180 watts. The transmitter and amplifier now send the received 449.250-MHz signal—at a much higher power level—back up to the repeater antenna on 444.250 MHz. This repeat function is exactly what greatly extends the range of an HT or a mobile radio! By using this repeater you have the equivalent of a 180-watt transmitter with an antenna at 480 feet!

Repeater Trustees are Rock Stars!

Hopefully this little tutorial has given you a better understanding of what goes on with the inner workings of a repeater system. When a repeater is up and running smoothly, almost everyone is happy, except for those poor chaps with nothing but an HT and an inefficient rubber-duck antenna in a low spot 20 miles from the repeater with hill in between, who complain that the repeater isn't working correctly. Perhaps this column will cause them to take pause and to think before speaking. Also, if perchance the repeater system ever malfunctions (and it will over time), don't be too quick to criticize the folks maintaining the repeater.

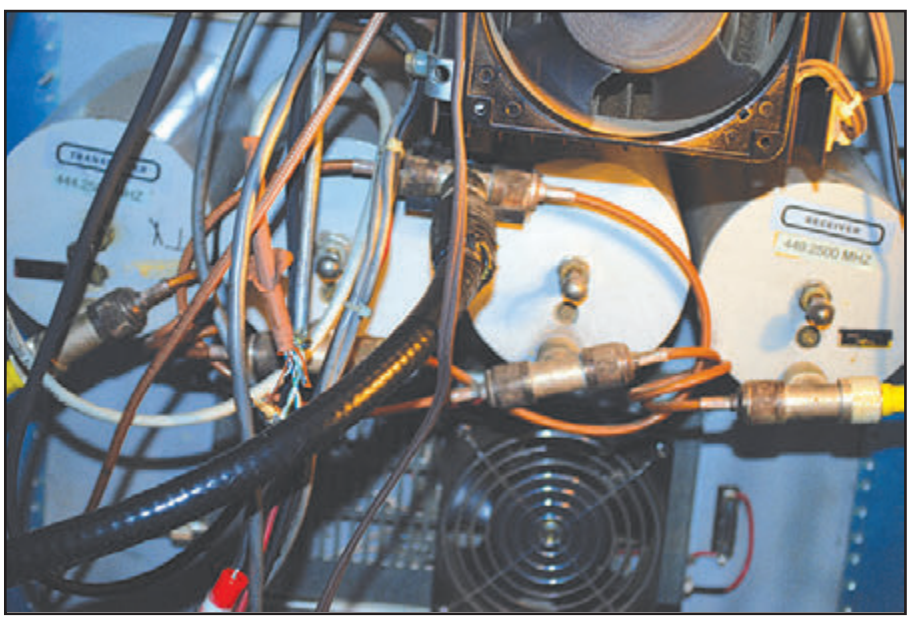

Photo G. These are the 70-centimeter duplexer "cavities," one pair each tuned to the WS9V input and output frequencies.

As you know now, there's a lot of work and a lot of expense in keeping up a system that we all take too much for granted. Therefore, the next chance you get and why not take a few moments to thank the repeater trustee for all that is done to make your daily work commute less boring and something that you even look forward to while in QSO with your buddies. That goes double when the repeater is needed during times of emergency. Please support all this work by joining the group that sponsors the repeater. 73, Ron, KOØZ

Photo 1. Simple installation of magnetic mount dual-band on the wheel well.

No Holes?

Many hams express concern at the notion of drilling holes in their car or truck, with good reasons. An interior hole can damage whatever lies behind the panel being drilled, be it wiring, a computer module, fuel line, sensor, or other device. In some hybrid or all-electric cars, a very powerful battery or high-current cables can also be present! Of course, too, exterior holes, if not properly done, can damage paint, bring on the beginnings of corrosion, and diminish the vehicle's value when it's time to trade or sell—unless of course you sell it to another ham who sees the utility of your installation.

Therefore, we'll share a very thorough story submitted by *CQ* reader Grady E. McCright W5GEM, who sent the following:

"Several years ago, I splurged and purchased a 2008 Ford F-250, Super Duty, mostly to pull my travel trailer but also to satisfy a long-held desire to own one. Immediately, I was confronted with the installation of a mobile VHF/UHF dual-band transceiver. I had no desire to mar the appearance of my new pickup, so I endeavored to generate a no-holes installation that would both serve me well and meet my criteria of punching no new holes in the vehicle.

"I decided to make do with a magnetic mount, so I purchased a popular-brand dual-band antenna. First I installed the antenna in the bed of the pickup for testing, and I just placed the strong magnetic base on the left-side wheel well (photo 1). The best location, of course, would be at the center of mass and as high as possible. However, since my car port is too low to accommodate such an installation, and since I, without thinking, purchased an aluminum tool box, I would have to crawl into the bed and put the antenna on the roof after taking off the cover each I used the vehicle, and then remove the antenna again before parking in the carport. Therefore, to avoid that tiring issue and after testing the antenna with an antenna analyzer, I chose the wheel well as the permanent location since it tested in the more than acceptable range. The best of both worlds would be leaving the feed line long enough to accommodate the roof installation and simply store the antenna on the wheel well. The roof would be preferred for longer trips and serious operation, yet the wheel-well location would work for casual local contacts.

"I continued with my no-holes installation by routing the feed line through an existing penetration in the front corner of the bed. That access hole was covered by an easily removable rubber plug which

Photo 2. Closed ashtray door that is slanted toward the driver.

Photo 3. Control head lying on the ashtray door with the door spring holding it in place.

Photo 4. Microphone in its nesting place under the seat. The power wires can be seen behind the mic going to the main body.

I saved for future re-installation. Although there are many ways to enter the cab with the coax, I chose to route mine along the frame to the engine compartment using plastic flexible ties to secure the cable. I then penetrated the firewall through the rubber seal around the steering column.

"There is another easy way for the feed-line cable to enter the cab by going through the small air vent behind the rear seat. These small vents allow a small amount of air exchange with the outside and also to permit the doors to close without compressing the air inside the cab. I have used this path on fire trucks in the past and it works fine. Nevertheless, since my truck is a super cab (once called a crew cab), I felt it easier to go through the firewall and not be required to route the cables under the floor carpet or mat to the front-seat area.

"Transceiver power is routed through a fuse in each leg directly to the battery via the same penetration along the steering column through which the coax goes. My dual-band transceiver is an ICOM IC-208 that has a detachable control head, so the body of the transceiver is installed under the middle of the front seat resting on a Sticky Pad (available from automotive stores and used to temporarily hold cell phones, GPSs, etc}. I laid the Sticky Pad on the carpet and then simply set the transceiver body on the top. This installation has been over some really rough roads in the western United States and I have had no trouble with movement.

"The coax cable, the power cord, as well as the remote-control-head interface cable all are routed from under the front of the rubber mats to the main body location beneath the front seat. Lying on top of the carpet and under the rubber mats has made a neat and serviceable installation. The route of the cables is from the center of the floor to keep the cables away from the driver's feet.

"My control head is a perfect fit in the ashtray, I simply opened the ashtray door and placed the control head on the drop-down door where the door spring holds the head securely. It does not move during operation or travel. It is canted toward the driver's position and is effortlessly visible, easily assessable, and convenient. (See the closed ashtray door in photo 2 and the control head installed in photo 3.)

"While one could use an adhesive-backed microphone holder in a suitable location on the dash, I really did not want that nor did I find a good position on the dash, and I could not locate anything metallic on the surface of the

Photos 5 & 6. Kentucky reader Wayne Whitman, K4ELO, sent along these photos of his very clean-looking installation on his pickup truck.

dash. Therefore, I took a magnetic mic holder and placed it on the driver's seat frame just under my right leg (photo 4). When in use, I place the microphone in the seat under the center armrest. Since the microphone is stored and used in close proximity to the main body of the rig, I plug the mic cable into the jack on the main body. If I had the mic clip mounted on the dash, I would use the jack on the remote head.

"I'm sure there are many other options for installing a modern, light weight, and small dual-band or even HF rig, but this method proved to be satisfactory for me and upon removal, my treasured pickup truck will still be pristine with no new holes."

Photo 7. N6ZE/Rover in the Santa Monica Mts, CA during the Spring 2012, 222 MHz Sprint Contest.

Thanks, Grady! Your clever installation should inspire many "no-holes" projects, much to the relief of nervous hams and their XYLs. Readers are reminded that Grady's tips apply to his particular vehicle. Be sure all cables are properly routed away from sources of heat and moving parts as well as computer modules, and other wiring whenever possible. (Also see photos 5 and 6, K4ELO's very clean-looking installation on his pickup truck.)

Winter Mobile Operation

Most drivers know that the extremes of winter operations stress your vehicle. Pre-winter and mid-winter checkups are important; making sure your antifreeze, battery and charging system, lights, wipers, and that all-important washer fluid supply is ready for foul weather. However, have you thought about your radio gear? Nearly every radio comes with an owner's manual that also lists the radio's performance specifications, including its temperature tolerances. A transceiver that's too cold, or too hot, can do some wacky things, like transmit off the displayed frequency (perhaps even out of band), or have its display show erroneous information. If you're in an area where temperatures hit extremes, it's a good idea to let your

NOAA Weather Frequencies

Here's a handy list of NOAA Weather Radio Frequencies to program into your transceiver:162.400, 162.425, 162.450, 162.475, 162.500, 162.525.

All frequencies are in MHz; FM mode.

rig warm up a bit before transmitting. Your mid-winter check should also inspect power and coax cables, antenna connections, and grounds. Another good practice is to set your rig's time-out-timer to shut it down after a period of disuse. Some transceivers also come with a third power connection that shuts down the radio when power from the ignition switch is cut. Either of these methods can help prevent you from coming out to that most dreaded winter automotive malady—the dead battery. If your car does require a "jump start" be sure the mobile rigs are shut down, as some pretty significant voltage spikes can occur when your battery is getting a boost. A cold engine start can pull voltage down pretty low, followed by a spike when it starts and the charging system roars to life.

One more tip: Many VHF transceivers have the ability to receive the NOAA weather radio frequencies. It's a good idea to program those into some of the extra memory channels most mobile and hand-held radios seem to have (see sidebar list).

Rover?

For readers in less chilly climates, the art of VHF/UHF mountain-topping is a ticket to adventure and a lot of contacts. Grid-square and WAS award-chasers value these intrepid individuals who literally "head for the hills" to provide contacts for others. A longtime friend who often crests the hilltops is Peter Heins, N6ZE (see photo 7).

While I don't recommend an alpine adventure during the winter months, mountain-topping can be an exciting and rewarding mobile/portable pursuit, especially for those who enjoy camping and the great outdoors.

Also, if you're searching for WAS or *CQ's* coveted USA-CA All Counties Award, join the County Hunter's group usually found on 14.336 MHz. Beside the contacts, the group listens for requests for assistance from motorists across the USA, something to keep in mind during the winter travel months.

Travel safely and remember that spring isn't that far away!

73 & Happy Mobiling . .

An Anniversary in the UK, FCC License Exams in South Africa, and Philippines Typhoon Wrap-up

I enjoy locating and reading old amateur radio magazines from the 1940s through '60s. It is amazing how much our hobby has changed in some respects and remained the same in others. Just when everyone was thinking that ham radio would "fade away," we remain strong and connected to other hams through our interests. Our first story is about a notable group in the UK that recently celebrated its 60th anniversary.

UK Emergency Group Marks 60th Anniversary

Just over sixty years ago—on November 25, 1953—the UK volunteer emergency communications group RAYNET (The Radio Amateurs' Emergency Network) was started. At the time, the UK had no such organization, and the need arose from a devastating storm that year that caused extensive damage and the loss of 307 lives. Evacuations were hindered by the lack of effective communications, and ham radio operators filled the gap.

Today, RAYNET serves as the UK's premier volunteer communications group with 2,000 licensed amateur radio operators as members (see: <http://www.raynet-uk.net/main/index.asp>). In an effort to advance emergency communications as well as amateur radio, RAYNET and the RSGB (Radio Society of Great Britain) have entered into a formal agreement to work together. RAYNET not only provides vital communications for emergency responders but also assists with public-service events.

Over the years, RAYNET has been activated numerous times, including the Lockerbie air crash in 1988, several floods, and a major oil spill.

Concerning RAYNET, Chairman Cathy Clark, G1GQJ, was quoted by the *Yorkshire Post* as saying: "... despite advances in technology, (RAYNET) is needed now more than ever. With our current unpredictable climate and the high risk of failure of modern communications networks RAYNET volunteers can make a crucial difference."

[Nevada Ham Radio.com and Southgate Amateur Radio News]

And also happening in the UK ...

West London Radio Fair at Kempton Park

The West London Radio & Electronics Fair has been held at Kempton for the last 11 years and attendance continues to grow each year. The most recent event, held in conjunction with the Radio Society of Great Britain (RSGB), took place on November 10, 2013 and was well attended by dealers, clubs, and amateurs from across the country.

The air-conditioned main hall of more than 8200 square feet attracted many of the clubs in the region to take a space along with flea-market traders and charities and included the regionally popular "bring and buy sale" where people bring items for sale and buy those that others have brought. Also popular were the many lectures and seminars and competitions, including the TOP HAM contest.

[RadioFairs.co.uk]

New VE Team to offer FCC License Exams in South Africa

The United States Federal Communications Commission (FCC) will issue an amateur radio license to anyone with a US mailing address—no residence or citizenship is required. One of the reasons for a ham living in another country to possess an FCC license is that it enables you to operate from countries with which the US has a reciprocal agreement even if your home country does not have such an agreement. It also allows you to operate within the US, even if there is no agreement in place between your country and ours.

Recently, four members of the C82DX DXpedition team who were operating in Mozambique in October, 2013 agreed to assist Chris Burger, ZS6EZ, a South African resident, in conducting an FCC testing session near Pretoria, South Africa. C82DX was an international team consisting of

*17986 Highway 94, Dulzura, CA 91917
e-mail: <aa6ts@cq-amateur-radio.com>

members from the United States, South Africa, Canada, and Japan (see <http://c82dx.com>).

Six South Africans qualified for American licenses—three for General Class and three for Amateur Extra. The newly licensed South African hams have planned to become VEs (Volunteer Examiners) in order to establish a permanent testing team in Gauteng, one of the nine provinces of South Africa.

A second exam was planned for December 2013. If you are interested in participating in a future testing session in South Africa, please contact Chris Burger, ZS6EZ, ARRL Volunteer Examiner via his QRZ.com page.

[ZS6EZ and South African Radio League (SARL)]

Philippine Typhoon Update

According to the Philippines Amateur Radio Association (PARA), when Typhoon Haiyan (locally named Yolanda)—the fiercest typhoon ever recorded on land and 3.5 times the strength of Hurricane Katrina—struck the central Philippines on November 8, 2013, killing at least four people and disabling virtually all communications services, the HERO (Ham Emergency Radio Operator) network of volunteers immediately began helping authorities with reports and messages and by tracking the storm and related outages of communications and other services. Reports estimate that more than four-million people were affected by the typhoon (see additional coverage in last month's "Public Service" column).

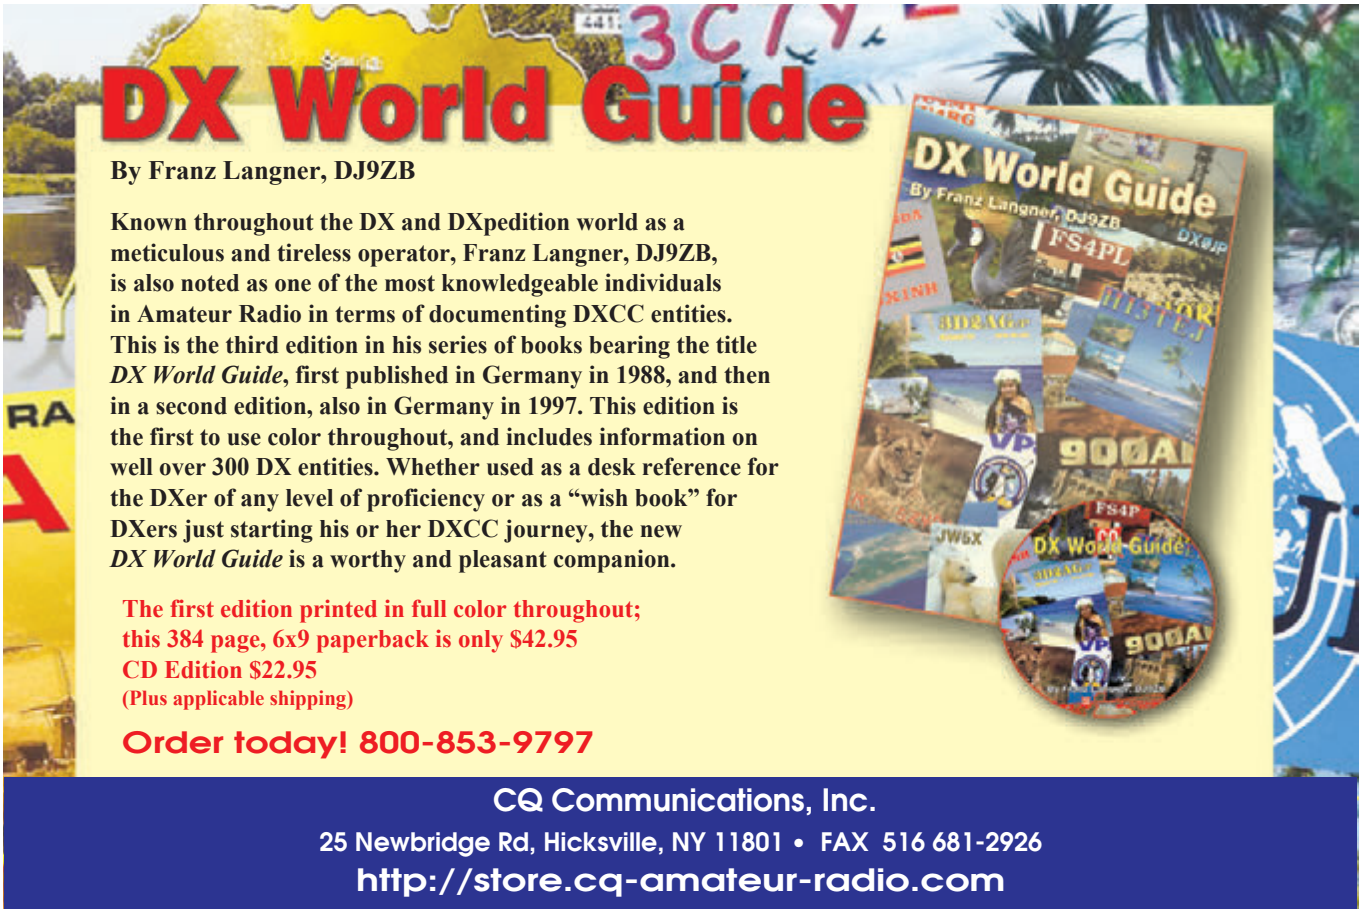
Ramon Anquilan, DU1UGZ, of PARA explained that amateur radio operations were conducted on 7.095 MHz, 144.740 MHz, and via social media. Ramon said that RADNET with Nathan Eamiguel, DU5AOK, Vilma Eamiguel, DU5VIE, and the members of their local club were operating an HF station located on the second floor of the Tacloban City Hall, powered by a generator maintained by the local government. (Tacloban is the capital of the Philippine province of Leyte and one of the places hardest hig by the storm.) Two-meter band communications were limited to simplex because there was no electricity to power their repeater.

In addition to the wind damage from the storm, flash floods and landslides caused even more misery, sending millions of people in 20 provinces to shelters, all of this occurring only a month after a 7.2-magnitude earthquake in October killed 222 people and left at least 5,000 sheltering in tents. The HERO Network also assisted in that disaster.

At least five amateur radio operations were active throughout the region, some in areas where over 90% of the structures were leveled. Many more stations receiving outgoing traffic from Tacloban and the other affected areas were scattered throughout the Philippines. Other stations were also active in receiving outbound welfare traffic, mainly to notify family members and relatives of their conditions.

DU1UGZ also reported that more than a week after being hit by the typhoon, PARA representatives attended a meeting chaired by the Commissioner of the National Telecommunications Commission, Gamaliel A. Cordoba, at which extended coverage was requested. Ramon, DU1UGZ, said, "Given the new task that NTC wants us to do, we will be needing stations that can be deployed and dismantled at a moment's notice. On the excellent offer of the ARRL, I have requested it to provide at least four HF stations and a repeater."

New HF and VHF stations were set up, and when necessary, equipment was replaced with new equipment. Lester,



Members of the C82DX team, shown here during their DXpedition to Mozambique, helped administer FCC amateur license exams in South Africa, where newly licensed Extras are starting their own VE team. (Courtesy C82DX website)

DV5PO, said that in one of the worst hit areas of Tacloban that has lost 90 percent of its buildings, the NORAD7 (Negros Oriental Radio Assistance Dumaguete) team had provided an additional HF station.

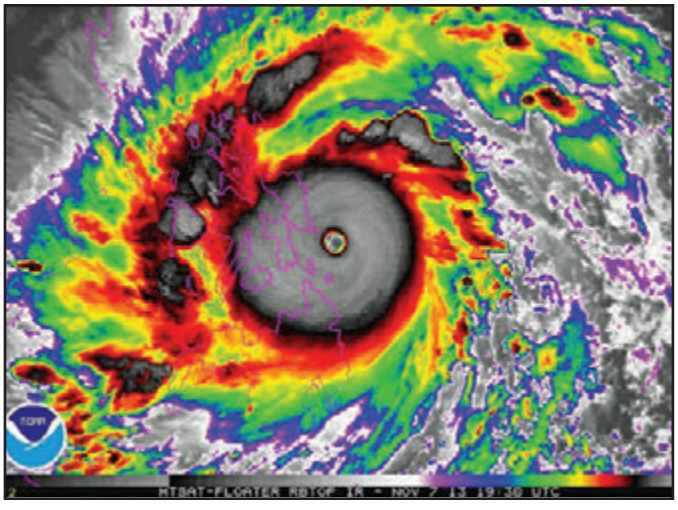
Assistance from many countries in the form of monetary donations, supplies, medical assistance, and manpower also began arriving. Earlier, the Philippine Consulate General in Guam and the United Filipino Organization said they would be starting fund drives to help victims of the super typhoon. Cell phone and Internet service were beginning to be restored as this was written, taking a lot of pressure off the ham volunteers, as victims and their families now have more options for keeping in touch and exchanging welfare reports.

Two weeks after the disaster, at the request of communication authorities in the Philippines, PARA began expanding locations and facilities and was hoping that requests for emergency communication gear, more repeaters, and even things such as more fuel for generators would be honored by the government and would provide the means for PARA's HERO network. Ramon, DU1UGZ, PARA's Vice-CEO, said the group had been working with the National Telecommunications Commission (NTC) and the National Disaster Risk Reduction and Management Council.

[Various news sources]

AA6TS comment: *People in the Philippines and other countries recently have had the unfortunate opportunity to deploy amateur radio operators to provide communications support under the worst of conditions and have had to meet extreme demands required by each situation. If any good is to come from these tragedies, it is my hope that emergency communication and disaster service volunteers from all countries are paying attention and taking notes, observing all of the unique situations that arose and noting how they were dealt with effectively so that each of us is better educated and prepared to deal with situations that might affect us at home. This author would like to extend sincere well wishes and gratitude to all of the amateur radio operators who volunteered their assistance.*

(Editor's note: As we prepared this issue for publication, we learned from ARRL that the Philippine HERO Network formally stood down on November 27 after several weeks of



Super typhoon Haiyan—one of the strongest storms ever recorded—left a path of death and destruction as it crossed the Philippines. Hams helped provide communications until normal channels were restored. (NOAA satellite photo)

Cebu Island in the Philippines (highlighted) is the home of a new RMS (Radio Message Server) system to provide digital amateur radio links to the Internet in the event of future large-scale communications outages. (CIA World Factbook map)

service, although four stations remained active in case additional needs arise.)

And in a related story . . .

Ham Radio RMS in the Philippines

In the wake of a major earthquake and a devastating typhoon, Jakob, DK3CW, reports that an RMS (Radio Message Server) has been installed on Cebu Island in the Philippines with WINMOR. Pactor (I/II and III), and other HF bands will be added later on, he says, as well as integration into the radio-only-WinLink network, to forward messages to another RMS outside the affected area if the communication infrastructure (including Internet) fails on Cebu Island.

The only other nearby WINMOR RMS is located in Australia (VK8AB), and propagation tests determined that VK8AB is not a reliable WINMOR RMS for the Philippines because of a high amount of timeouts and retries. Another RMS located in Indonesia (YBØAJZ) is only accepting PACTOR but not WINMOR for inbound sessions.

Frederick D. Medina, 4F7FDM, will be running the new system 24/7 using WINMOR 500 on 7036.5-kHz center frequency and VHF 9600-baud packet radio.

[DK3CW via Southgate Amateur Radio News]

Indian fishermen Want Free Ham Radio and GPS Gear

If you haven't heard about this yet, I want to share a story that I found both imaginative and perhaps disturbing at the same time—AA6TS:

According to India's *Deccan Chronicle*, there is a group of fisherman in that country that is upset about the lack of affordable and reliable communication equipment that they can use while deep-sea fishing, especially when they face severe storms. Currently, their only way to communicate location or safety-related information to their families is with mobile telephones that they claim are often unable to obtain a signal and have limited back-up power. Many are using portable FM broadcast radios to receive weather information.

Around 70,000 fishermen from several villages along India's coast have been demanding the state government provide them with free amateur radio gear and GPS equipment (as a subsidy) because they cannot afford to purchase this equipment on their own. They say that if they are equipped with amateur radio and GPS, it will help to get weather updates, receive directions, and find their location at sea to avoid impending danger.

The fishermen are backed by the president of the District Fisherman Welfare Association that was quoted in the article as saying that when the communication network fails during the storm, fishermen find no source of information unless they are equipped with ham radio and GPS to help them reach shore safely. The fishermen are awaiting a response from the government to their demand.

What caught my attention is the fact that the article did not mention any discussion of *licensing*, and I have a hard time believing that 70,000 fishermen are newly licensed but have not obtained their equipment yet. I will continue to watch this development with interest because I feel that the IARU would never condone the requested amateur radio equipment to be issued to unlicensed operators. I would delight in reporting in a future issue about the fact that India has added 70,000 new licensed amateur radio operators, not to mention the other family members at home! *(Another potential problem here is that the fishermen would improperly use ham gear for business-related communications.—ed.)*

Fishermen and boaters from all countries have discovered the benefits of obtaining an amateur radio license and having ham gear on-board for personal and emergency communications, but the fascinating part of this report is the huge number of potential new hams that are unified in their efforts to obtain amateur radio.

[Deccan Chronicle]

Until next month, please continue to share amateur radio news and happenings from your country. Send your stories and photos to <aa6ts@cq-amateur-radio.com>.

Teenager Leads ISS Contact

School contacts with the International Space Station have become so routine that most of the time they are no longer covered in places such as this column. Therefore, it is news when something special happens during one of those contacts.

Something special did happen during the November 13, 2013 ISS contact: Sixteen-year-old Rebecca Rubsamen, KJ6TWM, was the lead engineer for the contact between students at Rancho Romero Elementary School and astronaut Mike Hopkins, KF5LJG. Rubsamen of Alamo, California, is a sophomore at Bentley School in Lafayette and built her own Elecraft™ K3, which included 2 meters. In her backyard she also built the two antennas used in the contact.

Rebecca's interest in amateur radio got started by her father, Reid Rubsamen, N6APC, two years before the contact. Not to be content with ordinary QSOs, she learned about the ISS and satellite communications so that she would be able to return to her former elementary school and lead this ISS QSO.

As we know, it is a tough process to be selected for an ISS contact. NASA and the Amateur Radio on the International Space Station (ARISS) arrange for about 50 contacts per year. Undaunted by her age, she applied for and received permission to be one of the youngest lead operators for an ISS contact.

According to Ashle Harris, a NASA spokes person, last year there were around 68 permissions granted. While most of them were international contacts, 20 were with stations in the U.S., of which three (including this one) were with California stations.

While Tim Bosma, W6MU, was the ARISS-assigned mentor for the contact, Rebecca ran everything from arranging the station's setup to making sure that the students were in queue so they could ask their questions. Tim was quite impressed with her professionalism, adding that he had not seen anything quite like it in his approximately thirty years of being a mentor. During the nearly 8-minute QSO most of the 15 students were able to ask Mike their questions. The audio of the contact can be found at: <http://www.youtube.com/watch?v=dDv0m-7C4Oo>.

Rebecca maintains a website (http://www.rebeccarubsamen.com/photos.html) in which she has posted a number of photos pertaining to the run-up to the launch. Among the photos is one with astronaut James Van Hoften and her on Science Night at her school. In that photo she displays her K3 and the 12-volt power supply that she used to power it. Local media coverage was supplied by the Contra Costa Times. Here is a link to its story: <http://www.contracostatimes.com/news/ci_24517766/headline>.

While it may be a tad bit too early for Rebecca to think about her career aspirations, it is clear that she already knows how to achieve what she sets her mind to do. Look for her to make more headlines in the not too distant future. Hopefully for our hobby, she could be making those headlines in connection with amateur radio.

Hector Martinez, CO6CBF, now also KF5YXV

This past November Hector Martinez, CO6CBF, earned his U.S. Technician class amateur radio license. He is probably the only Cuban national to also hold a U.S. amateur radio license. Here, from Southgate Amateur Radio News service is how he was able to become a licensed U.S. amateur radio operator:

The idea was first conceived during the 30th AMSAT Space Symposium in Orlando 2012 by Clayton Coleman, W5PFG, after hearing Hector Martinez, CO6CBF's desire to operate with his own callsign during his visit to the United States. Because there is no reciprocal agreement between the U.S. and Cuba, he was not able to do so.

A workaround was for Hector to earn a U.S. amateur radio license. At that time he was able to identify three Volunteer Examiners. However, they lacked the materials to test Hector at that time.

Fast forward one year to the 31st AMSAT Space Symposium in Houston.

A few weeks before the Symposium, Clayton contacted the AMSAT-BB, asking for AMSAT members who were ARRL or W5YI VEs to contact him in order to see if we might be able to set up a testing session for Hector. Clayton received many responses and four ARRL VEs stepped up

Shirley, N8LX, and Lynn, N8LXK, Roberts at the Handiham booth during the 2011 Hamvention™. See note at end of this column. (Photo courtesy Handiham)

e-mail: <n6cl@sbcglobal.net>

to assist the effort. Douglas Phelps, K9DLP, took the lead as Team Liaison and brought testing and filing materials with him. Others joining the team included EMike McCardel, KC8YLD, Patrick Stoddard, WD9EWK, and Jerry Buxton NØJY.

Late Thursday evening, rather serendipitously, three of the VEs happened to find themselves in the same place at the same time. Shortly thereafter Clayton, W5PFG, Patrick, WD9EWK, and Hector also happened by. The team immediately went into planning mode to set up a time and place to conduct the test, preferably early Friday. Then came the suggestion, why wait? Everyone is here, so why can't we do it now? When the team asked Hector if now would be good, his immediate response was, "Yes, yes, now!"

The team went to their rooms to collect their credentials and materials and then convened 15 minutes later in a quiet, well lit area of the hotel lobby and presented Hector with a copy of the Technician Exam. Hector took it and passed the exam.

The next morning the exam materials and application were forwarded on to the ARRL VEC by means of US Postal Priority mail, which assured delivery by Monday noon, in hope that his license would be granted before his return on Wednesday. At shortly before 3 pm CST Monday Hector's license cleared the FCC ULS database and he officially was granted callsign KF5YXV. We can't laud Maria Somma, AB1FM, and the folks at the ARRL enough for their efficiency.

Minutes after all became aware that Hector had been assigned his callsign, he began working the birds. Clayton reports, "We had a blast on Monday evening through Wednesday working every satellite pass available to us. He was as exciting to watch as a kid getting his license for the first time."

Hector adds, "Thanks very much for all your help and the great time! It was very fun to operate for first time on AO-7 mode B."

Congratulations to Hector and all who participated in this expression of International Goodwill.

Thanks go to Clayton Coleman, W5PFG, EMike McCardel, KC8YLD, and AMSAT News Service for the above information.

FUNCube-1 Satellite Launched

During the middle of November, 37 satellites carrying amateur radio payloads were launched. Among them was the much anticipated FUNCube-1 satellite, now designated AO-73. Here is the AMSAT-UK FUNCube website: <http://funcube.org.uk/>.

VK Waits for Full Return of the 6-meter Band

The following, from Jim Linton, VK3PC, by way of Southgate Amateur Radio News Service:

With only digital television being available in Australia from 10 December, and the loss of the last TV transmitter Channel 0, it does not automatically mean the unfettered return of 50–52 MHz to the amateur radio service.

Restrictions listed in the Licence Conditions Determination (LCD) on operation of amateur stations in Australia's eastern states on the lower end of 6 metres remain effectively in force until the document is changed by the Australia Communications and Media Authority (ACMA).

Channel 0 came on air in Australia in the 1960s, which meant radio amateurs lost the bottom 2 MHz of 6 metres.

Australia expanded its TV analogue allocation because of the need for more channels and so was born 45–50 MHz or Channel 0, initially for commercial telecasters, then the Special Broadcasting Service, and for translators.

The Melbourne and Brisbane telecasters left Channel 0 and became Channel 10, while the gap was filled by SBS, with it eventually settling on UHF Channel 28.

The Wireless Institute of Australia (WIA) has long argued that the 50–54 MHz band should be retained for, and allocated exclusively to, the amateur service, once the existing Channel 0 transmitters are removed.

The 50-MHz or so-called "magic band" is important to radio amateurs because it provides unique opportunities for propagation experiments.

The WIA has again written to the ACMA seeking the unrestricted return of the band. The latest letter on the subject last month is yet to be answered.

The ACMA reminded all in July this past year of their LCD obligations in relation to the 6-meter restrictions.

On previous occasions the limited resources of the ACMA have meant the change waits until the Australian Radio Frequency Spectrum Plan is amended, and that usually occurs in January.

The WIA has made a number of submissions to the ACMA on the subject over the years seeking a harmonization in Australia with the practice overseas.

The WIA is also to amend the Regulations licence assessment questions to reflect any change, while at the same time it will beef up its electromagnetic radiation emphasis in the papers from 2014.

Radio Amateurs Say Hi To Juno

The following is from AMSAT-UK (http://amsat-uk.org/2013/10/09/radio-hams-say-hi-to-juno/):

Radio amateurs around the world took part in an experiment with NASA's Juno spacecraft as it did a flyby of Earth. NASA's Juno spacecraft flew past Earth on Wednesday, October 9, 2013 to receive a gravity assist from our planet, putting it on course for Jupiter.

To celebrate this event, the Juno mission invited amateur radio operators around the world to say "HI" to Juno in a coordinated Morse Code message that would be detected by Juno's radio and plasma wave experiment, called Waves.

Radio amateurs transmitted Morse (CW) signals on a range of frequencies between 28.001 and 28.450 MHz. To give a random spread the precise frequency used depended on the last character of each station's call sign. The natural signals the team expect to measure at Jupiter will consist of a large number of discrete tones, so spreading the signals out in this manner was a good approximation to the signals Juno is expected to detect. But at Jupiter, they don't expect to be able to decode CW in the telemetry!

The Waves instrument is sensitive to radio signals in all amateur bands below 40 MHz. However, experience with the University of Iowa instruments on the Galileo and Cassini Earth flybys showed significant shielding by the ionosphere at lower frequencies, so the 28 MHz band was chosen for the experiment.

Juno's antenna consists of a pair of tapered 2.8 meter long titanium tubes, deployed from the bottom deck of the spacecraft under the +X solar array and magnetometer boom. A high impedance radiation resistant preamp sits at the base of the antenna and buffers the signals from 50 Hz

to 45 MHz. The elements are deployed with an opening angle of about 120 degrees. 28 MHz is above the resonant frequency of the antenna and NEC analysis indicates a lobe generally along the spin axis of the spacecraft. This will be good for detection on the inbound part of closest approach to Earth.

The Waves instrument uses four receivers to cover the frequency range of 50 Hz to 41 MHz. Signals up to 3 MHz are bandpass filtered, sampled by A/D converters and FFT processed into spectra using a custom FFT processor developed by The University of Iowa under a grant from the Iowa Space Grant Consortium.

Among those taking part were students at Virginia Tech using their club station K4KDJ. Here is a video of that effort: <http://www.youtube.com/watch?v=OaCRnSQf9sE>.

More on Juno

The following is from Southgate Amateur Radio News:

When NASA's Juno spacecraft flew past Earth on October 9, 2013, it received a boost in speed of more than 7.3 kilometer per second, which set it on course for a July 4, 2016 rendezvous with Jupiter, the largest planet in our solar system

During the flyby, Juno's Waves instrument, which is tasked with measuring radio and plasma waves in Jupiter's magnetosphere, recorded amateur radio signals. This was part of a public outreach effort involving ham radio operators from around the world. They were invited to say "HI" to Juno by coordinating radio transmissions that carried the same Morse-coded message. Operators from every continent, including Antarctica, participated. The results can be seen in this video clip at <http://photojournal.jpl.nasa.gov/archive/PIA17744.mov>.

Watch a four-minute video depicting the efforts of a few of the many amateur radio operators who participated in the event here: <http://www.youtube.com/watch?v=_yqHy_MpNiQ>.

One of Juno's sensors, a special kind of camera optimized to track faint stars, also had a unique view of the Earth-moon system. The result was an intriguing, low-resolution glimpse of what our world would look like to a visitor from afar.

"If Captain Kirk of the USS Enterprise said, 'Take us home, Scotty,' this is what the crew would see," said Scott Bolton, Juno principal investigator at the Southwest Research Institute, San Antonio. "In the movie, you ride aboard Juno as it approaches Earth and then soars off into the blackness of space. No previous view of our world has ever captured the heavenly waltz of Earth and Moon."

Watch the Juno Earth flyby movie with a music accompaniment by Vangelis here: <http://www.youtube.com/watch?v=CzBlSXgzql>.

The cameras that took the images for the movie are located near the pointed tip of one of the spacecraft's three solar-array arms. They are part of Juno's Magnetic Field Investigation (MAG) and are normally used to determine the orientation of the magnetic sensors. These cameras look away from the sunlit side of the solar array, so as the spacecraft approached, the system's four cameras pointed toward Earth. Earth and the Moon came into view when Juno was about 600,000 miles (966,000 kilometers) away—about three times the Earth-Moon separation.

During the flyby, timing was everything. Juno was traveling about twice as fast as a typical satellite, and the spacecraft itself was spinning at 2 rpm. To assemble a movie that wouldn't make viewers dizzy, the star tracker had to capture a frame each time the camera was facing Earth at exactly the right instant. The frames were sent to Earth, where they were processed into video format.

"Everything we humans are and everything we do is represented in that view," said the star tracker's designer, John Jørgensen of the Danish Technical University, near Copenhagen.

"With the Earth flyby completed, Juno is now on course for arrival at Jupiter on July 4, 2016," said Rick Nybakken, Juno project manager at NASA's Jet Propulsion Laboratory in Pasadena, California.

The Juno spacecraft was launched from Kennedy Space Center in Florida on August 5, 2011. Juno's launch vehicle was capable of giving the spacecraft only enough energy to reach the asteroid belt, at which point the sun's gravity pulled it back toward the inner solar system. Mission planners designed the swing by Earth as a gravity assist to increase the spacecraft's speed relative to the sun, so that it could reach Jupiter. (The spacecraft's speed relative to Earth before and after the flyby is unchanged.)

After Juno arrives and enters into orbit around Jupiter in 2016, the spacecraft will circle the planet 33 times, from pole to pole, and use its collection of science instruments to probe beneath the gas giant's obscuring cloud cover. Scientists will learn about Jupiter's origins, internal structure, atmosphere and magnetosphere.

And Finally . . .

Some of you who have seen my wife, Carol, W6CL, and me at the Dayton Hamvention™ have also seen us with Shirley, N8LX, and Lynn, N8LXK, Roberts. Shirley was Hamvention's Ham of the Year in 2011. Now Shirley is battling breast cancer. I ask you to please keep her in your thoughts and prayers. Also, please send her an e-mail of encouragement to: <n8lx@earthlink.net>.

This is all the news I have room for in this issue. Thanks to all . . .

73 de Joe, N6CL

what's new

Firmware Upgrade for ICOM IC-7800 Transceiver

ICOM America has released a new firmware upgrade for its popular IC-7800 HF/6-meter transceiver. Features include:

- Spectrum Waterfall Display
- PC Mouse Operation via USB
- Audio Scope Function
- Direct Remote Control Operation via the Internet
- Digital Voice Recorder

The firmware upgrade may be downloaded from the IC-7800 product page on the ICOM website at <http://bit.ly/JIfKEe>.

Note: *"What's New" is not a product review and does not constitute a product endorsement by CQ. Information is primarily provided by manufacturers/vendors and has not necessarily been independently verified. The purpose of "What's New" is to inform readers about new products in the marketplace. We encourage you to do additional research on products of interest to you.*

QRP Awards, plus a Very Short-Term Award

It's usually difficult to be able to feature very short-term awards in this column because the column is written well in advance advance of the time you receive your copy of CQ. However, first is an exception. The Punxsutawney Area Amateur Radio Club has published its rules to offer its annual "Ground Hog Day" certificate (it's free!).

For our overseas readers, the "Ground Hog" is also known as a woodchuck, a rodent belonging to the group of large ground squirrels known as marmots. The woodchuck is a lowland creature. It is widely found in North America.

Ground Hog Day is celebrated on February 2. According to folklore, if it is cloudy when a groundhog emerges from its burrow on this day, then spring will come early; if it is sunny, the groundhog will supposedly see its shadow and retreat back into its burrow and the winter weather will continue for six more weeks. (Thanks Wikipedia)

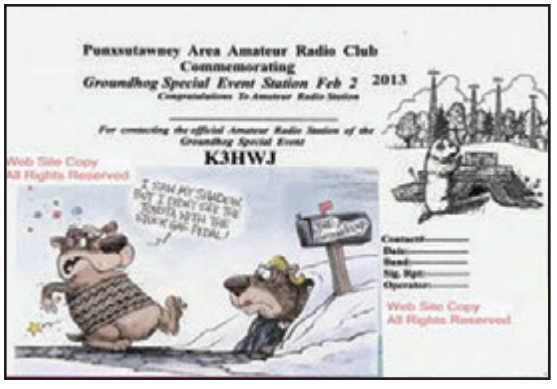
USA Ground Hog Day Special Event Certificate

Make just one contact with the Punxsutawney Radio Club station K3HWJ on Saturday, February 2, 2014 from about 9:00 a.m. until at least 3:00 p.m. or later depending upon band conditions. Look for activity on the following frequencies:

40 meters on or about 7183 ±about 5 kHz
20 meters on or about 14330 ±about 5 kHz
80 meter backup on or about 3845

Send your QSL card and a self-addressed, stamped envelope to: Punxsutawney Area Amateur Radio Club, Groundhog Contact No. ___, P.O. Box 3, Punxsutawney, PA 15767. Note: Put your contact number in the "___" above. This will help the club to process the certificate.

*12 Wells Woods Rd., Columbia, CT 06237
e-mail: <k1bv@cq-amateur-radio.com>



The Punxsutawney Area Amateur Radio Club has published its rules to offer its annual short-term "Ground Hog Day" certificate

USA-CA Honor Roll

500	2000
SMØMEM 3623	DK2OY 1437

The total number of counties for credit for the United States of America Counties Award is 3077. The basic award fee for subscribers is $6.00. For nonsubscribers it is $12.00. To qualify for the special subscriber rate, please send a recent CQ mailing label with your application. Initial application may be submitted in the USA-CA Record Book, which may be obtained from CQ Magazine, 25 Newbridge Road, Hicksville, NY 11801 USA for $2.50, or by a PC-printed computer listing which is in alphabetical order by state and county within the state. To be eligible for the USA-CA Award, applicants must comply with the rules of the program as set forth in the revised USA-CA Rules and Program dated June 1, 2000. A complete copy of the rules may be obtained by sending an SASE to Ted Melinosky, K1BV, 12 Wells Woods Road, Columbia, CT 06237 USA. DX stations must include extra postage for airmail reply.

Internet: <http://www.punxyclub.com/special-events/ground-hog-day>

QRP Awards

Have you ever tried QRP? Most modern rigs will let you crank the power down to 5 watts or less for tuning purposes. Here are some QRP awards from the major and minor clubs that specialize in this area of ham radio.

The first is from the QRP ARCI International (QRPARCI) , probably the largest club of its type in the USA. It offers a dozen awards. Follow the link below in the rules to view all offered.

USA QRP ARC Series – Worked All States Award. QRP is defined by the QRP ARCI as using no more than 5 watts output on CW and 10 watts PEP output on SSB. This award is available to any amateur operator. Application forms may be found on the club's website: <http://www.qrparci.org/arciawds.html>. The fee for all awards or endorsement certificates for W/K amateurs is $US4, or for non-W/K $US5 or 10 IRCs. In addition, e-QSLs are now accepted. There are endorsements for band and mode, etc. Apply to:

The QRP ARCI Series Worked All States Award.

On the Cover

Dave Clausen, W2VV, is a co-founder of the NYC Resistor in Brooklyn, New York—the first "makerspace" in the United States—and trustee of its club ham station, N2YCR, where he is operating in the photo.

A ham since 2008, Dave's main interests are QRP (appropriate for our QRP Special!), portable operating, and activating summits for SOTA, the Summits on the Air program. He also enjoys building kits.

Dave's interest in ham radio came out of his involvement in NYC Resistor, which he helped to found in 2007. "I had no particular interest in radio," he recalls, noting that his main interest at the time was working with microcontrollers. "But one guy in the club had his license; I got mine, and so did others." Dave notes that the maker group is not a ham radio club as such, although there is a ham club that's part of it (N2YCR), and that there's "lots of overlap."

Dave says he sees more interest and excitement about ham radio among younger people today than five to ten years ago, and thinks one way to recruit more young people is through broader-based groups, such as a maker group, that include ham radio as part of their activities.

For readers who are not familiar with makerspaces or hackerspaces, Dave describes NYC Resistor as part clubhouse, part social group, part workspace with shared tools, and part business incubator. Several businesses have gotten their start there, he explains, most notably MakerBot, of which fellow co-founder Bre Pettis, W2BRE, is CEO. The group sponsors classes and holds weekly craft nights, which are open to the public as well as to members.

A software engineer for Google, Dave also has been the cameraman for many of the popular ham radio videos produced by his wife and fellow NYC Resistor co-founder Diana Eng, KC2UHB. And yes, they met at the club!

(Cover photo by Larry Mulvehill, WB2ZPI)

Just one QSO, of 100 kilometers or more, using 1 watt or less, qualifies you for the QRP$_p$ Award.

QRP ARCI Awards Chairman, QRP ARCI Awards Manager, Julio A Jimenez ,3341 Eastgate Street, Eastover, NC 28312, USA.

E-mail: <awards@qrparci.org>, Internet:<http://www.qrparci.org/content/blogsection/4/116/>

QRP All States Award. This award is issued to any amateur for confirming QSOs with stations in 20 or more of the 50 states of the USA while running QRP. A satellite endorsement is available. Endorsement certificates are issued at 30, 40, and 50 states confirmed. A satellite endorsement is available.

USA QRPp Low Power Award. Successfully using extreme low power to make contacts over long distances is always a fascinating subject. A long time ago, when I was newly licensed, I used just my VFO to call a big shot DXer a few towns away, and the antenna was a mismatched long wire. Yes, he heard me, sent QRZ? and his callsign at high power. I was convinced that QRP could really work.

This award was developed in order to encourage more low-power amateur radio operations.

1. Make one QSO using power of less than one watt. The output power during the period of qualifying communications was accurately measured to be less than one watt (QRPp).

2. The distance between the applicant's transmitting antenna and the receiving station was over 63.3 miles (100 kilometers).

3. No artificial means of active relay was used to complete the communications (i.e., repeaters, satellite transponders, digi-peaters, land-lines, etc.).

4. Send a signed statement to the custodian affirming that the transmitter power was less than one watt, the distance was greater than 100 kilometers, and no artificial means of active relay was utilized. Provide a photocopy of the station log, or photocopy of the confirmation QSL card (electronic QSL cards are not acceptable), clearly showing the date, time, mode, and frequency on which the qualifying communication took place. If desired, provide information concerning any endosements (such as longer distances, even lower power levels, WAC, WAS, WAZ, solar power, etc.) that you may want listed on your certificate.

5. Mail fee of $4.00 ($5.00 for foreign), to cover postage, paper, and printing along with the application materials shown above to: Roger J. Wendell, WBØJNR, QRPp Certificate Manager, P.O. Box 17174, Golden, CO 80402-6019 USA. Internet: <http://rogerwendell.com/qrpaward.html>

Italy's I-QRP Award. I like this one from Italy. Both sides of the QSO do not have to be made using QRP. It's somewhat hard to contact stations that both must use QRP to make and complete a contact. Here, if you are the QRP station and contact the Italian station who is using non-QRP, you still get credit, if only 1 point. And there are many, many Italian stations on the air, so your chances of being heard, under good conditions, with QRP are pretty good.

Earn a minimum of 50 points by contacting at least 25 Italian QRP stations. If both stations use QRP, each QSO = 2 points; if only you use QRP, the contact is worth 1 point. All bands may be used, including WARC. Each station may only be contacted one time. Send GCR list and fee of 7 Euros, $US7, or 7 IRCs to: Marcello Surace, IK7HIN, via Dante 239, I-70122 Bari, Italy.

E-mail: <marcello.surace@tiscali.it>; List of I-QRP members: <http://www.arimontebelluna.it/i_qrp/contest.htm>

We are always interested in learning of new awards for this column. Please contact me with any details; a URL on the internet would be fine.

73, Ted, K1BV

Italy's I-QRP Award.

Isn't ham radio a fantastic hobby? There are so many different types of transmission modes and interesting areas a person can focus on. County Hunting is an area I started to work on many years ago and have never regretted the trip.

I was introduced to ham radio by some of my father's friends. My dad served in the Army Signal Corps during WW II, stationed in Alaska working in the Alaska Communication System. He wore headphones many hours a day for three to four years, hearing incoming code and typing it on the "mill." When he came home from the war, he was not interested in pursuing ham radio like many of his other signal corps buddies. My first radio recollection was visiting the home of one of his wartime friends and seeing his station. "Mack" Mackie, W7IJY(SK), was the first operator I ever knew, and I will never forget the warm glow of his station and the places he could talk to. Three decades later, when I got my ticket, I was thrilled to be able to have a QSO with him.

In the mid-1980s, married and with a family, I met my soon-to-be Elmer, Tom, WA7TC, who got me going on the code and license, and then into homebrewing antennas. With Tom, my ham skills were further practiced in ARES/RACES, SAR, and American Red Cross communications in Grays Harbor County, Washington.

Thumbing through a copy of CQ magazine one day, I became interested in the several awards that were offered by confirming contacts. I chose to work on the CQ USA-CA Counties Award, and spent the next 22 years toward its completion. There were many years of interruption because of moves, and a job that required many hours away from home, not to mention the obligation of raising a young family. Chasing counties is a hobby that can be put aside and come back to easily when you have time. I love the county hunting nets because you don't have to sit there for hours. It only takes seconds to get a needed county contact, and then you can go back to whatever you were doing.

Checking my logs, I see my first contact on the 14.336 County Hunter net was with Milt, KYØE, mobile in Apache, AZ, on May 19, 1991. My last contact, for the "whole-ball-of-wax" was with Bob, N8KIE, on October 10, 2013 from Towns, GA. Bob went out of his way in his recent trip to get my last four counties, two in KY and two in GA. Since there are 3,077 counties, there were a lot of other fantastic people between those two contacts.

Special thanks go to Bob, N8KIE, obviously. Also to Tom, WA7TC, for being such a great Elmer, and to Terry, WQ7A, and Bob, K7TM, for their help and inspiration. Several people helped with completing states in the last few months; NA8W, NØKV/NØDXE, WG9A, N8HAM, KM9X, and K5GE. I am sure there are more I have missed, and I am thankful for you as well. There are several CW operators who were very patient and forgiving of my fist, as I started to make the switch a few years ago, seeing that the path to the finish would come a lot faster on CW. A few of those great CW operators deserving mention are WØGXQ, N4CD, W7FEN, K1TKL, W4SIG, KC7YE, and K7TM. Also, special thanks to my wife, Darlene, who has listened to so much QSB as we drive, and the seemingly endless contacts as I give out a county. She has more patience than any ham operator I have ever worked.

I have met many mobile operators at the past MARAC conventions, and the friendships that have been made are wonderful. I want to thank the numerous county hunters for all the counties and the fantastic job of the net controls and relays. They are first-class operators, and they have made this possible. *. . .UR 599 EWA TU. —Paul, N7JP*

A Look Back at 2013 and a Report from South Sudan

First off, I must apologize profusely for the mix-up last month. I finished the January column while spending more than 12 hours at John F. Kennedy International Airport in New York waiting to fly to Europe to join the Z81X DXpediton to South Sudan. Somehow, while traveling I failed to pass the column to CQ Headquarters. It seems I could have hand-delivered it! Once out of the country, access to the secure areas of my ISP were blocked. My ISP people said that it was normal, but I wonder...

Thus, with *this* column, I start the year 2014. This month I will include some of January's material, which was a review and update some of the topics that I talked about in my 2013 DX columns starting with April 2013. I will conclude with some thoughts—and photos—from the Z81X expedition.

April – Introduction

My April column contained a little bit about me and a little bit about my philosophy of DXing. I mentioned DXing skills and the lack thereof. What I didn't mention was the fun that I had in the early days and since. When I was much younger, talking to others in distant locations was very intriguing, and I always said that I someday would like to visit some of the people whom I meet on the radio. That "dream" has come true for me. Your prior DX column editor, Carl Smith, N4AA, often said that no matter what your focus, having fun is, in fact, what this hobby is all about. What we older DXers might regret is that newer hams our age don't have the same opportunity to appreciate such communications. However, that's life, and we need to cope with it. The young folks have their own joys, and we elders need to understand that.

May – DXing Tips, Thoughts on Kosovo

May brought some DXpeditioning tips and more thoughts on Kosovo. Recently, Rick, K6VVA, has made it a career to study pile-up behavior, and he has identified some interesting traits. I believe the most useful is that many DXers don't *really* know what's happening in a pile-up—whether the DX operator is speeding along at 39.9 words per minute or on SSB near the noise level. Communicating with the pile-up where, when, and how to call is imperative. To accomplish this, slower CW and clarity and repetition on SSB are vital. Languages and accents must be accounted for.

On CW, I don't mean 15 words per minute, but a comfortable 26–30 wpm is a good speed, slower perhaps if conditions are more difficult. Sending "UP" after every QSO is helpful, and sending your callsign at least every three QSOs is mandatory. Even using these techniques, it is impossible for everyone to know exactly what is going on if the operator isn't consistent.

On phone, it is equally important, but somewhat easier to communicate effectively with the pile-up. Keeping in mind that not all DXers in the world speak English as a first language is essential. In the end, we need to be more understanding of what is going on in a pile-up, especially the so-called "cops" who wish to keep the DX frequency under control, but usually are more QRM than those calling on the wrong frequency. If the DX op fails to inform the callers, chaos will ensue.

I also discussed the status of Kosovo. This new country is recognized by CQ and the German Amateur Radio Club (DARC). It is still not recognized by the ARRL and its DXCC program. In July, however, the ARRL Board tasked the DX Advisory Committee with reviewing *all* DXCC rules. Two of the important issues within that task are to consider country status criteria and remote-control operation. We can only presume that additional discussion will have taken place at the Board of Directors' January meeting.

And, again, I have gotten carried away until…

June – Too Much DX? And a Look at DXpedition Funding

For the June column, I lamented having to work the Pacific DXpeditions during the early hours of the morning. Four a.m. and I have never gotten along too well, and now in early November (when this column was originally written), I am again having to get used to these dark, early hours in order to scoop up whatever DX might be available in the Pacific on Topband. Ah well, whatever it takes.

The main topic in June, however, was DXpedition funding. Don, K1DG, had presented a paper describing where in the world DXpedition funds come from, and I counseled consideration of local customs and traditions regarding donations and charity.

In that column, there was an announcement of a large NCDXF grant made to the Amsterdam Island DXpedition due on the air last month. Reasonably large expenditures for such difficult destinations may be appropriate. Yet it may be that such large contributions only perpetuate the idea that the super-large-scale expeditions are feasible. The infrequency of such operations seems to beg for the largest possible range of band and modes, and the largest possible number of contacts. However, when the total cost approaches $8 to $10 per QSO, some rethinking might be in order.

Complete rules and application forms may be obtained by sending a business-size, self-addressed, stamped envelope (foreign stations send extra postage for airmail) to "CQ WPX Awards," P.O. Box 355, New Carlisle, OH 45344 USA. Note: WPX will now accept prefixes/calls which have been confirmed by eQSL.cc. and the ARRL Logbook of The World (LoTW).

*Please Note: The price of the 160, 30, 17, 12, 6, and Digital bars for the Award of Excellence are $6.50 each.

Indeed, some rethinking has been occurring. The organizers of another DXpedition to such a southern spot have concluded that the expense for transportation is absolutely excessive. These folks are now considering a stripped-down effort with limited exposure, a limited number of operators and number of QSOs, and—most importantly—a greatly reduced budget. The thinking is that an expedition that can give everyone one to three contacts is better than no expedition, and certainly better than QSOs at a cost of near $15 or even $20 per QSO. All of this sug-

5 Band WAZ

As of December1, 2013 1850 stations have attained at least the 150-zone level, and 911 stations have attained the 200-zone level.

New recipeints of 5 Band WAZ with all 200 zones confirmed:

DL5AN

The top contenders for 5 Band WAZ (zones needed on 80 or other if indicated):

The following have qualified for the basic 5 Band WAZ Award:

N1WQ (172 zones)	9A2NO (172 zones)
ON6KE (150 zones)	KB4CL (163 zones)
DL7KL (170 zones)	

5 Band WAZ updates:

ON4CAS(194 zones)	LU5OM (200 zones)
F4GTB (173 zones)	

***Please note: Cost of the 5 Band WAZ Plaque is $100 shipped within the U.S.; $120 all foreign (sent airmail).**

Rules and applications for the WAZ program may be obtained by sending a large SAE with two units of postage or an address label and $1.00 to: WAZ Award Manager, Floyd Gerald, N5FG, P.O. Box 449, Wiggins, MS 39577-0449. The processing fee for the 5BWAZ award is $10.00 for subscribers (please include your most recent *CQ* mailing label or a copy) and $15.00 for nonsubscribers. An endorsement fee of $2.00 for subscribers and $5.00 for nonsubscribers is charged for each additional 10 zones confirmed. Please make all checks payable to Floyd Gerald. Applicants sending QSL cards to a *CQ* checkpoint or the Award Manager must include return postage. N5FG may also be reached via e-mail: <n5fg@cq-amateur-radio.com>.

gests that we might need to reconfigure the thinking that every DXpedition must cater to the needs of those chasing the DXCC Challenge, and even more so, the competition engendered by the Club Log phenomenon. Is such extravagance good for DXing? Increasingly, we are just saying "No!"

By the time this column appears in print, we will know how the planned January DXpedition to Amsterdam Island ended. In early December, the Amsterdam Island webpage is stating that if they make 100,000 QSOs, each QSO will cost about $4.00. Although not the $10 to $20 per QSO that is envisioned for larger expeditions, it is still excessive. Budgets like that beg the question of whether we are thinking of all possible scenarios. I have said that such efforts will continue as long as they can be funded. Will such funding continue into the future? Or will DXers say "enough!"? Are there alternatives? The DX University will begin studying the issue in the coming months. If you have suggestions and alternative scenarios, please visit the DX University website and register your thoughts in the "Contact Us" section.

July – Remote-Control DXing

For July, I wrote about remote-control DXing. This topic has been simmering for some time. I must have been prophetic, because the ARRL Board of Directors resolved in July to ask the League's DX Advisory Committee to "…study and, if warranted, recommend changes to the DXCC Rules for the ARRL Board of Directors to discuss." There are probably two primary issues: One is that DXCC rules now rely primarily on the whims of the United Nations, which is currently paralyzed on some issues by the prospect of a veto. As a result, it appears that unless the DXCC rules are augmented, it will be a long time before Kosovo—*and other potential entities*—count for DXCC. Since this was published, we have come to further understand that *no ITU prefix will be forthcoming any time soon*. Hopefully, the DXAC and the BoD will grasp what this means and act accordingly. I will reserve judgment.

The other major issue is remote control of amateur radio stations. Through advances in Internet-based devices, it is simple and inexpensive to control your station from anywhere in the world. Many hams don't understand just how extensive the possibilities are: remote control of whole stations, control of receivers on other continents, control of mega-stations owned by others, virtually anything you can think of, and more. Remote control is not in the future. It is *now*. It's legal in most cases, and rules that attempt to regulate or restrict it are totally unenforceable.

August – DXpedition Fairness: "Who to Work"

The August column dealt with fairness by DXpeditions in working all areas of the world. If a DXpedition operates from the Indian Ocean, DXers in the western USA might have to scramble to make even a single contact. Low-band contacts to that area are even more difficult. The difficulty in making QSOs between relatively remote locations can be alleviated by DXpedition operators listening at the proper times for certain locations. This isn't always easy to do, but operations in recent months have done a reasonably good job in this respect.

September – Back in the Day, Some DXing History

The September column was something else! I just look at the picture of KN6ALH (me) in 1953 and shake my head. Certainly lots of DX has come and gone since then. Such a way to measure your life! I guess to stay young we need to keep making DX.

October –The DXPP

Closely tied to the matter of DXpedition funding is that of the DXPP, the *DXpedition Paying Passenger.* The term DXPP has been viewed by some as derogatory, but I believe it is important to first understand what it means. The DXPP is an amateur with (1) time, (2) resources, and especially (3) a good attitude and a willingness to learn the ropes. Of course, the DXPP might not even be interested in operating, but perhaps is simply interested in traveling to a remote location, or possibly just observing the whole thing. Unfortunately, if inadequately prepared or supervised, the DXPP can be a serious liability for a DXpedition. These operators are not capable of running pile-ups efficiently, can give the expedition a bad name, and among other negatives, make future fund raising difficult.

Since October's column I have learned another term. It's the *Inverse*

Endorsements

WØOVM.....(SSB 196)

The basic award fee for subscribers to *CQ* is $6. For non-subscribers, it is $12. In order to qualify for the reduced subscriber rate, please enclose your latest *CQ* mailing label with your application. Endorsement stickers are $1.00 each plus SASE. Updates not involving the issuance of a sticker are free. All updates and correspondence must include an SASE. Rules and application forms for the CQ DX Awards may be found on the <www.cq-amateur-radio.com> website, or may be obtained by sending a business-size, self-addressed, stamped envelope to CQ DX Awards Manager, Please make checks payable to the Award Manager, Keith Gilbertson. Mail all updates to Keith Gilbertson, KØKG, 21688 Sandy Beach Lane, Rochert, MN 56578-9604 USA. We recognize 341 active countries. Please make all checks payable to the award manager. Photocopies of documentation issued by recognized national Amateur Radio associations that sponsor international awards may be acceptable for CQ DX award credit in lieu of having QSL cards checked. Documentation must list (itemize) countries that have been credited to an applicant. Screen printouts from eQSL.cc that list countries confirmed through their system are also acceptable. Screen printouts listing countries credited to an applicant through an electronic logging system offered by a national Amateur Radio organization also may be acceptable. Contact the CQ DX Award Manager for specific details.

DXPP. This individual is such an expert at certain aspects of DXpeditioning, working exclusively on 160 meters, for example, that he is encouraged to come along on a DXpedition on a reduced or no-cost basis. Essentially, the remainder of the participants or even the foundations support these people because of their expertise. The Inverse DXPP.

November – The DXAC's New Assignment

Following up on my July premonition, I noted in November that the ARRL BoD asked the DXAC to study several issues. In fact, the board asked the DXAC to review *all* DXCC rules and report back. By the time you read this, the committee will have written an interim report, which most likely will have been reviewed by the ARRL Board at its January meeting. By the time this appears, we may well be hearing of progress by the DXAC.

December – DXing with a Modest Station

In the December column, I discussed how one might work DX with a modest station. When I solicited input, I was universally asked, "How do you define a modest station?" Generally, I consider a modest station to be one running 100 watts with an antenna that will fit on a small city property. Since hearing from some DXers who are running such stations, I find that they do very well, beating me out in many pile-ups. (Maybe my station is more modest than I thought.) What that says is that waiting for better or the best propagation will win out every time. Since this was written, we have had more excellent conditions, more sunspots. Perhaps this is the answer for those with modest stations.

There you have it, my thoughts from April through December 2013 with some updates. What will 2014 bring?

Missionary DXpeditioning from South Sudan

The mission of the November DXpedition to South Sudan, Z81X, was two-fold. First, it was to present a workshop on amateur radio to the Ministry of Telecommunications in Juba. While I don't have the space here to discuss this fully, I can say that a whole day was spent with the Director General of the Ministry and 20 other members of that administration. A presentation was made by Hans Blondeel Timmerman, PB2T, president of the IARU, Region 1; Martti Laine, OH2BH; and your columnist, with information on (1) Training regulators in the administration of the amateur service; (2) Assisting the administration in the creation of amateur radio regulations and related frequency table; (3) Discussing amateur radio's benefits for the society; and (4) Evaluating the prospects of establishing the amateur radio service for South Sudanese nationals. Several pictures taken at this workshop accompany this column.

The DXpedition Operating from South Sudan

While it's still fresh in my mind, I also want to make some observations about the operating I observed while operating Z81X from Juba, South Sudan at the end of November 2013.

CQ DX Honor Roll

The CQ DX Honor Roll recognizes those DXers who have submitted proof of confirmation with 275 or more ACTIVE countries. With few exceptions, the ARRL DXCC Countries List is used as the country standard. The CQ DX Award currently recognizes 341 countries. Honor Roll listing is automatic when an application is received and approved for 275 or more active countries. Deleted countries do not count and all totals are adjusted as deletions occur. To remain on the CQ DX Honor Roll, annual updates are required. All updates must be accompanied by an SASE if confirmation of total is required. The fee for endorsement stickers is $1.00 each plus SASE. (Stickers for the 340 level are available.) Please make checks payable to the Award Manager, Keith Gilbertson. Mail all updates to Keith Gilbertson, KØKG, 21688 Sandy Beach Lane, Rochert, MN 56578-9604 USA.

The South Sudan workshop group, including Hans, PB2T; Martti, OH2BH; and Wayne, N7NG. See text for details.

Much has been said in recent years about the deteriorating operating ability and skills of the world's DXers. Overall, my experience doesn't support much of what I consider so much hand-wringing.

To start, I have to admit that my own operating revealed some roughness around the edges, particularly at the beginning. Besides having spent considerable time recently DXing rather than DXpeditioning and running pile-ups, dealing with unfamiliar equipment took its toll. Imagine sitting down at a station and realizing that the keyboard is in German (or Spanish) and that not all of the keys are in the same position as I was accustomed to. I did have my own computer with the same software, but changing them between shifts seemed initially more of a pain that it was worth.

The actual operating was lots of fun. On only a few occasions did I find the pile-up out of control, with stations calling when they should have been listening. Most of this was understandable, and when it was necessary to regain control, repeating a partial callsign several times proved sufficient.

There were only a few instances in

The workshop attendees were treated to a catered lunch. (OH2BH photo)

which I had to deal with stations calling out of turn to the point that I couldn't copy the desired station. There were also a few situations in which my frequency was being QRMed by stations calling me on the wrong (my) frequency. I did note a few of these cases where my rate suffered—because people couldn't hear me due to the QRM on my frequency—and I had to change my frequency by a few hundred Hertz. Generally, however, my rate was up to standards, indicating that the pile-up management was satisfactory. (Note that it doesn't really matter what *you* think of the QRM on my frequency. It's what *I* hear that is important.) Before we terminated the operation, I asked some of the operators (OHØXX, OH6KN, DL3DXX) what they thought of the operating in the pile-ups. Generally, their impressions were positive. They had no significant complaints. My own experiences echo their observations.

Next month I'll talk a little more about the South Sudan trip and also a little about an out-of-the-box possibility for organizing QSOs on an extreme DXpedition.

73, de Wayne, N7NG

Hans, PB2T, addresses the workshop group. (OH2BH photo)

VHF Propagation

by Neubeck, WB2AMU & West WB6NOA

A comprehensive source-book on VHF propagation by two great authors. Includes: Tropo ducting, Aurora, Meteor Scatter, TEP, Sporadic-E, Combo Modes and more!

6 X 9 Paperback $15.95

The NEW Shortwave Propagation Handbook

by W3ASK, N4XX & K6GKU

This authoritative book on shortwave propagation is your source for easy-to-understand information on sunspot activity, propagation predictions, unusual propagation effects and do-it-yourself forecasting tips.

8.5 X 11 Paperback $19.95
***New!* CD Version $14.95**
Buy both for only $29.95

W6SAI HF Antenna Handbook

by Bill Orr, W6SAI

W6SAI was known for his easy-to-understand writing style. In keeping with this tradition, this book is a thoroughly readable text for any antenna enthusiast, jam-packed with dozens of inexpensive, practical antenna projects that work!

8.5 X 11 Paperback $19.95
***New!* CD Version $14.95**
Buy both for only $29.95

33 Simple Weekend Projects

by Dave Ingram, K4TWJ

Do-it-yourself electronics projects from the most basic to the fairly sophisticated. Practical tips and techniques on creating your own projects.

6 X 9 Paperback $17.95

Shipping & Handling: USA - $7 for 1st book, $3.50 for 2nd, $2 for each additional. **CN/MX** - $15 for 1st, $7 for 2nd, $3.50 for each additional. **All Other Countries** - $25 for 1st, $10 for 2nd, $5 for each additional.

BY GEORGE TRANOS,* N2GA

Can Contesting be Successful as a Spectator Sport?

Anyone is allowed to compete in amateur radio contests, regardless of their previous experience, skill level, or equipment. Get on the radio, put out a signal, make contacts, and you're part of the event! Even the least-experienced novice operator can make contact with the best of the best. As a matter of fact, the best operators *want* to interact with everyone—novices through experts.

So why doesn't everyone contest? Part of what intimidates some people about contesting may be the pages of rules and the seeming complexity of top-notch stations. That can also keep a spectator from appreciating the operating skills, decision-making, and effortlessness of the best contesters. Wouldn't it be nice to see and hear the best operators in the world right from their operating location? Can this be done in a way that allows contesting to become a successful *spectator sport* as well as a participation sport?

You can compare an amateur radio contest (also called *radiosport*) to a major sporting event. Watching sports is big business. Fans around the world spend many hours attending, listening to, and watching sporting events on television and the Internet. These events attract major advertisers who pay large fortunes to have their commercials play during them. Major sports are covered by media worldwide and produce some of the largest viewing audiences. The excitement created during and leading up to spectator sporting events is looked forward to by a major percentage of the world's population. Amateur radio competition should be no different, as it offers its own brand of excitement.

*P.O. Box 657, Copiague, NY 11726
e-mail: <n2ga@cq-amateur-radio.com>

Similarities

An amateur radio contest has a finite length of time, the contest period. This is equivalent to a "game"in any other sport. There is a distinct winner, along with second-, third-, and fourth-place achievements. The rules are available for anyone to follow. There are periods of great activity, such as a huge pile-up with many operators calling in at once, leading to high rates of contact. There are technological challenges similar to other sports, such as bobsledding or sailing, in which sophisticated software modeling contributes to maximizing the performance of the necessary equipment.

Operators from all continents and hundreds of countries participate in worldwide amateur radio contests. Contest spectators may want to cheer for operators from their country (or state or radio club, etc.), just like fans want to root for their home team. Hams may personally know and like some of the participants and this may form a bond for the spectator as well.

In most contests, operators from many different categories operate all at the same time but are only

competing against rivals in their own category. This is similar to some types of auto racing, in which different car classes drive on the same racetrack but only vie for positions within their own class.

Differences

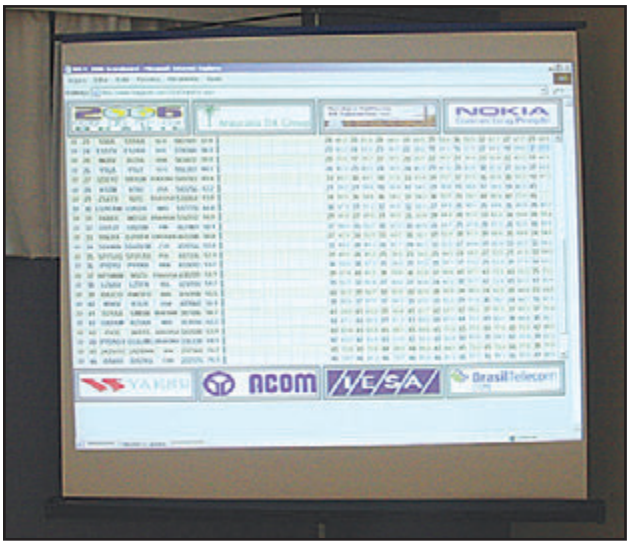
Contesters are geographically distributed and may be anywhere in the world. It may be difficult for a spectator to "watch" the competition from any one spot. When the contest is over, the raw scores can be compared to determine the winner, but the real winner is not known until log checking is performed. That might be "good enough" for the spectator, but the final results may show a different order of finish from the raw score, and that process takes several months.

Ingredients Needed for Success

When you're watching your favorite sports team, don't you want to know the background of the players? In a contest, wouldn't it be great if a spectator could know who the radio operators are and some background information about them personally as well as their station's information? The observer should be able to view the competition as it takes place in real-time, as if they were viewing the contest at each participant's location. There should be a way to compare the score and activity of each operator to other similar stations.

A necessary component for someone to observe and analyze the competition as a spectator would be a scoreboard. The current contest and time remaining should be shown. Without the ability to see the whole event at once, a viewer should be able to see a leaderboard with the competitors listed in order from highest to lowest. To make things more interesting, this scoreboard should show information right from the operators' logging programs. The callsign used, category entered, and current score are the basics. Other data that might make viewing more interesting include the current QSO rate for the last 10 and last 100 contacts; hourly breakdown of score, number of contacts, and multipliers; current active band; station and frequency of last contact.

There are existing websites such as getscores.org, Club Log, and others that provide a basis for just such a scoreboard. Computer program interfaces already exist between most contest logging programs and these websites. This is the key to real-time score reporting. As each contact is logged, it should update the scoreboard so spectators can see the latest score.



The scoreboard at the World Radiosport Team Championship 2006 in Brazil. Note listings for the placement and operator callsigns of each team, total score, and other information. (Photos courtesy of Diane Ortiz, K2DO)

Virtual Visiting

A nice option would be for a spectator to click on one of the callsigns to actually view and hear the operation currently in progress from that station. Video and audio could then be pulled up for the selected operator. For CW and RTTY contesting, a visual display of the on-air audio could show the contest operation as it takes place. Both sent and received information should be shown so the spectator could watch the contest in its entirety. Other logging windows as displayed on the operator's screen should also be available to allow the fan to view the operator display and be "in the cockpit" with the operator. The spectator should then have the option of switching to a competitor's station. All the same options would be available. Other operators should have the option of determining if they're in the log. This would allow others in the contest to participate and "spectate" at the same time!

Some other things that might create excitement would be the ability to compare callsigns. The viewer could select, say, up to three stations, and current data would be shown on the screen side-by-side. This real-time information would change every time a contact is logged. Comparative statistics would show which station is growing its QSO rate and which is slowing.

Other interesting items for viewers would be the station and antenna setup. Where is the station located? Is it on a mountaintop with views in all directions or is the operation on a small city lot? Station setup is a big part of contesting

The scoreboard at WRTC 2006 was visible at the headquarters hotel as well as over the Internet. People gathered to view the contest as it was taking place.

today, but operator ability distinguishes the top scorers from the also-rans. Some great operators do a fantastic job from a small station but can't compete with the leaders because the hardware is just not there. Knowing this helps the spectator put the station performance in perspective.

Statistics are other areas where fans glean information and can debate about sports. Contesters have histories that are available for comparison. How did this station do last year or the year before in the same contest? How does that compare with the second- or third-place operator? The more information there is available, the more interesting the contest can become to a fan.

Summary

Contesting is an exciting sport but it's hard to demonstrate that excitement to non-contesters. If we can find a way to highlight our sport and actually show it in operation, we could perhaps get more hams interested in contesting. We might also be able to entice the general public into becoming ham radio operators and contesters. Kids today are really interested in gaming and online competition, and ham radio contests are very similar. If we could find a way to show them how exciting ham radio contesting can be, then they might want to get involved.

Could we get to the point where radiosport is treated like other spectator sports? That might be a stretch, but we currently have the technology to provide a more fan-friendly environment. Anything we can do to highlight the achievements and activity of contesters will go a long way toward promoting our sport and providing new blood for future contests. While contesting is already a growing activity in ham radio, it might expand even faster if non-contesters saw for themselves the fun and camaraderie the sport has to offer.

73, George, N2GA

Wouldn't it be nice to be part of the action by tuning into video and audio right from the contest site? Here's the operation of contest station PT5G by Pat Barkey, N9RV, and Tim Duffy, K3LR, during the World Radiosport Team Championship 2006. It took place at the station of PP5JR in Sambaqui, Brazil.

WRTC 2006 had stations spread out throughout the southern portion of Brazil. With Florianopolis as its headquarters, stations were distributed up and down the coast."

Looking Ahead in CQ *and* CQ plus

Here are some of the articles we're working on for upcoming issues of *CQ*:

- **Results, 2013 CQ World-Wide RTTY DX Contest**
- **Results, 2013 CQ World-Wide Foxhunting Weekend**
- The CW Neighborhood
- 3 Scientists … and their Radio Roots

… and in the new CQ-Plus:

- The HI JUNO Project
- "Elmering" in the Internet Age
- Making the Most of AM BCB DXing Tools
- The 100-mW "AM Transmitter Challenge"

Upcoming Special Issues

June: Take it to the Field
October: Emergency Communications
December: Technology

Do you have a hobby radio story to tell? Something for one of our specials? *CQ* now covers listening and personal two-way services in addition to amateur radio. See our writers' guidelines on the CQ website at <http://www.cq-amateur-radio.com/cq_writers_guide/cq_writers_guide.html>.

Equinoctal Propagation

BY TOMAS HOOD,* NW7US

Beginning about the middle of February and continuing through March and early April, typical equinoctial propagation conditions can be expected on the HF frequencies. This usually means a noticeable improvement in conditions between the northern and southern hemispheres. Look for improvements between the United States and South America, Africa, Australasia, Antarctica, and parts of Asia. Equinoctial propagation occurs during the spring and fall months, when the sun is most directly overhead at the equator, producing similar ionospheric characteristics over large areas of the world. It tends to maximize during sunrise and sunset periods and over both short- and long-path openings.

LAST-MINUTE FORECAST

Day-to-Day Conditions Expected for February 2014

	Expected Signal Quality			
Propagation Index.....	(4)	(3)	(2)	(1)
Above Normal: 2-6, 8-12, 14-18, 22-27	A	A	B	C
High Normal: 13, 19-21	A	B	C	C-D
Low Normal: 7	B	C-B	C-D	D-E
Below Normal: 1, 28	C	C-D	D-E	E
Disturbed: N/A	C-D	D	E	E

Where expected signal quality is:
A—Excellent opening, exceptionally strong, steady signals greater than S9.
B—Good opening, moderately strong signals varying between S6 and S9, with little fading or noise.
C—Fair opening, signals between moderately strong and weak, varying between S3 and S6, with some fading and noise.
D—Poor opening, with weak signals varying between S1 and S3, with considerable fading and noise.
E—No opening expected.

HOW TO USE THIS FORECAST

1. Find the *propagation index* associated with the particular path opening from the Propagation Charts appearing in *The New Shortwave Propagation Handbook* by George Jacobs, W3ASK; Theodore J. Cohen, N4XX; and Robert B. Rose, K6GKU.

2. With the *propagation index*, use the above table to find the expected signal quality associated with the path opening for any given day of the month. For example, an opening shown in the Propagation Charts with a *propagation index* of 3 will be poor (D) to fair (C) on Feb. 1st, excellent (A) from the 2nd to the 6th, Fair (C) to good (B) on the 7th, etc..

3. As an alternative, the Last-Minute Forecast may be used as a general guide to space weather and geomagnetic conditions through the month. When conditions are Above Normal, for example, the geomagnetic field should be quiet and space weather should be mild. On the other hand, days marked as Disturbed will be riddled with geomagnetic storms. Propagation of radio signals in the HF spectrum will be affected by these conditions. In general, when conditions are High Normal to Above Normal, signals will be more reliable on a given path, when the path is ionospherically supported.

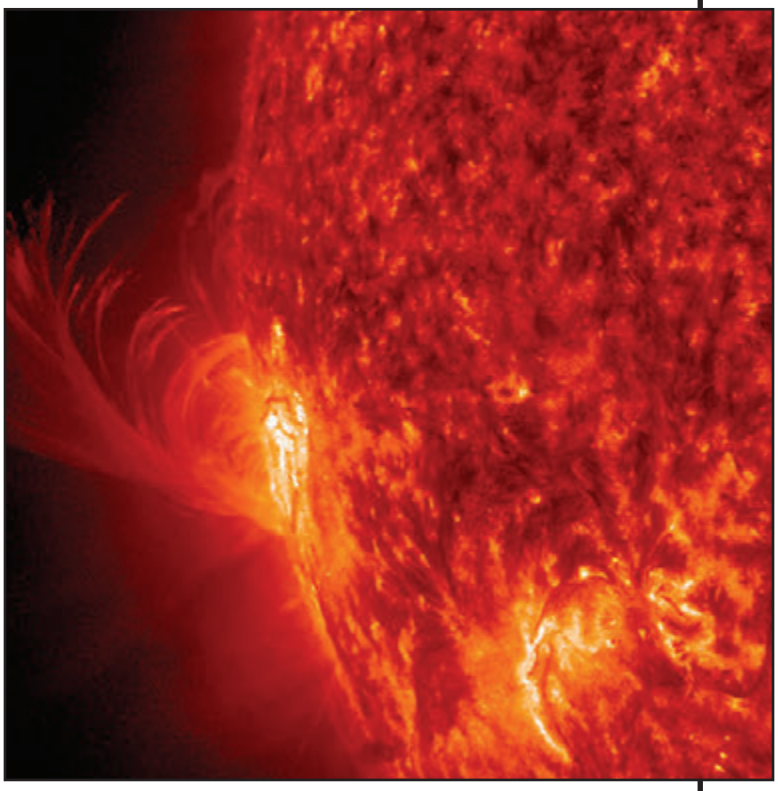

Fig. 1. The Sun burst out with a curling spray of plasma from an active region just coming into view on December 5, 2013. A number of smaller bursts also erupted from the same region, including at least one flare. All of the activity has its source in turbulent magnetic forces associated with the active region, the bright area seen in this image as the bright "patch" out of which the plasma sprays. The video at <http://g.nw7us.us/1dEMN4O>, taken in extreme ultraviolet light, covers about 5.5 hours beginning at 01:00 UTC (notice the x-ray flare, seen as a bright flash). This image was taken at about 02:52 UTC. (Credit: Solar Dynamics Observatory [SDO]/NASA)

During the daylight hours, optimum DX propagation conditions are expected on 15 meters. The band is forecast to open to all areas of the world sometime during this period, often with strong and stable signals with little fading or noise. Openings will be a bit shorter than those of the last few years. Conditions on 10 and 12 meters should run a close second, but with fewer openings expected into Europe and the Far East. Excellent worldwide DX openings to most areas of the world are forecast for 17 and 20 meters during the daylight hours. Conditions are expected to optimize for an hour or two after sunrise and again during the late afternoon. With increasing hours of daylight during February, expect the 10-, 12-, 15-, 17-, and 20-meter bands to remain open for an hour or so longer into the early evening than during the winter months.

Although the solar cycle is meandering along, be sure to check the 6-meter band for possible DX openings, particularly when a number of C-class or higher x-ray flares are occurring, and when the 10.7-cm flux is climbing. Openings are expected to be less numerous than in previous years of higher solar activity, but some openings may still be possible during the hours of daylight. The best bet is for openings toward Central and South America, but other openings may also be possible.

During the early evening hours and to as late as midnight, seven bands should be available for DX openings—15, 17, 20, 30, 40, 80, and 160 meters. Fifteen and 17 meters should hold up for openings toward Central and South America and the Caribbean, the Pacific area, Far East, and parts of Asia. Even better openings to many areas of the world should be possible on 20 meters during this period, with the strongest signals from southerly and westerly directions. Good DX conditions are also forecast for 30, 40, and 80 meters for openings toward the east and the south. Openings in the same direction, but with higher noise levels and weaker signals, should also be possible on 160 meters.

Between midnight and sunrise it should be a toss-up among 20, 30, and 40 meters for DX paths. These bands should open to many areas of the world with conditions favoring openings towards the south and the west. Expect similar conditions on 80 meters, but with weaker signals and higher noise levels. Be sure to check 160 for some unusual DX openings toward the south and the west during this period. Conditions on the bands between 160 and 20

CQ WW CW Contest Conditions

As you may remember, I predicted good to excellent conditions for the 2013 CQ WW CW Contest starting at 0000 UTC Saturday, November 23, and running through 2359 UTC Sunday, November 24. The weekend was, at least by the reports I've received, well within the prediction. The planetary Ap on the first day was a low eight on the first day, falling to a very quiet two by the second day of the contest.

With such quiet geomagnetic conditions, the lower HF bands were great players during the night; weaker signals were easier heard on those bands where openings provided signals weak yet present. During the day, the higher bands played nicely, as well.

The 10.7-cm radio flux was 136 on Saturday and 127 on Sunday, and the observed sunspot count on the first day was 65, while on the second day it was 69. There were ten minor C-class x-ray flares, and two M-class flares on day one. On day two, there were also 10 C-class flares. This activity helped higher-band propagation, but caused a bit of degradation on lower bands. These conditions still provided reasonable propagation on many of the contest bands. These conditions fit pretty well with the forecast.

How did you fare this year compared to last year? I am interested in hearing from you regarding the differences between last year and this year, and how you did overall this time.

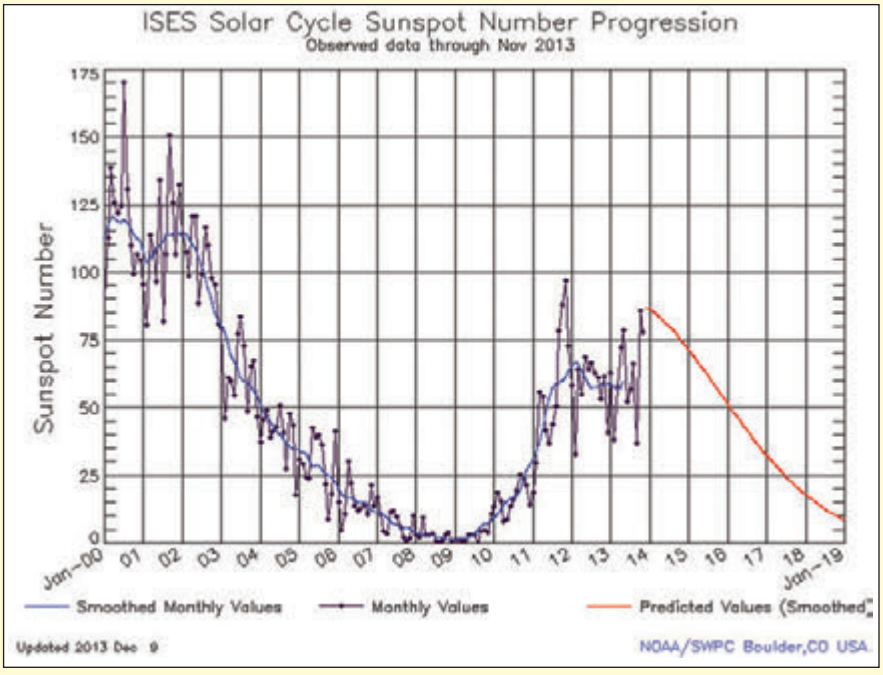

Fig. 2. The plots of current sunspot Cycle 24, as of December, 2013, reveal a significant increase of solar activity during the last months of 2013. While this cycle is much weaker than a number of past solar cycles, this recent uptick in activity has breathed new life in the high-frequncy amateur radio allocations. One might postulate that there is a second peak in Cycle 24. Keep in mind that, magnetically, the Sun is showing signs of reversing polarity (where the north and south solar poles are reversed), a sure sign that we're approaching the down-turn marking the decline phase of the cycle. (Credit: SWPC/NOAA)

meters are expected to peak at local sunrise.

VHF Ionospheric Openings

As mentioned previously, check for 6-meter DX openings during the daylight hours. Some short-skip openings over distances of about 1200 to 2300 miles may also occur. Best times for such openings are during the afternoon hours.

Trans-equatorial (TE) scatter propagation tends to increase during the equinoctial period, and some 6-meter openings may be possible between 7 and 10 PM local time. The best bet for such openings is between the southern tier states and South America for paths approximately at right angles to the equator. An occasional TE opening may also be possible on 2 meters. Unlike F_2-layer or sporadic-*E* openings on 6 meters, TE openings are characterized by very weak signals with considerable flutter fading.

Auroral displays tend to occur somewhat more frequently during the equinoctial period. Unusual short-skip conditions often occur on the VHF bands during these displays. Openings, generally over distances of several hundred and up to about 1300 miles, may take place by means of reflection from

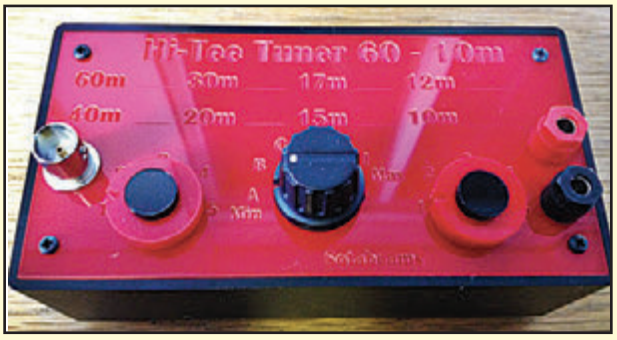
what's new

New Products from SOTAbeams

"Hi Tee" QRP Antenna Tuner

UK-based portable accessory specialists SOTAbeams has introduced the first in its new range of antenna tuners. The Hi Tee Tuner has been designed with performance and weight in mind, according to a company announcement. It weighs just over 5 ounces (150 grams) and covers 60–10 meters.

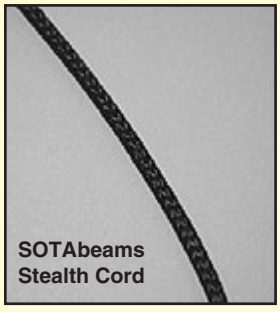
Unlike many QRP tuners, the company says, an air-core coil is used to minimize losses. The tuner has been optimized for portable use, although it is just as much at home in the shack. It includes space on the front to fill in the settings for each band for your favorite antenna. The tuner retails for just over $80US at current exchange rates (plus shipping). For more information, visit <http://www.sotabeams.co.uk/hi-tee-tuner/>.



SOTAbeams "HiTee" QRP Antenna Tuner

SOTAbeams Antenna Cords

Sometimes you want your antenna supports to be as invisible as possible; other times you want high visibility. The folks at SOTAbeams, who specialize in portable antennas, are now offering both options. On the hard-to-see side is *Stealth Cord,* a thin, woven nylon cord consisting of a green and brown weave. Formulated to have low visual impact, it is ideal for holding up stealth antennas. Stealth Cord is supplied on a spool in a generous 50m (160 ft) or 200m (720 ft) lengths, for approximately $12 and $28 US, respectively, plus shipping.



SOTAbeams Stealth Cord

For times when safety is more of an issue than stealth, SOTAbeams also is offering a new "hi viz" cord designed for use on busy hilltops or in emergency situations. It comes in the same lengths at the same prices. Both products are available in SOTAbeams' web-store at <www.sotabeams.co.uk>.

Note: *"What's New" is not a product review and does not constitute a product endorsement by CQ. Information is primarily provided by manufacturers/vendors and has not necessarily been independently verified. The purpose of "What's New" is to inform readers about new products in the marketplace. We encourage you to do additional research on products of interest to you.*

the ionized region produced by an auroral display. Flutter fading and multi-path echoes characterize auroral-type openings. To take maximum advantage of such openings, rotatable antennas should be beamed toward the auroral display, if it is visible.

Large areas of sporadic-*E* ionization also accompany most auroral displays. Reflection of VHF signals from these regions can make possible short-skip openings between distances of 750 and 1300 miles. Signals reflected in this manner are usually strong and stable as compared to those reflected directly from an auroral display.

Auroral activity often occurs during periods of radio storminess on the HF bands. Check the Last-Minute Forecast (also available online at <http:// SunSpotWatch.com>) for those days expected to be Below Normal or Disturbed during February. These are the days on which VHF auroral-type openings are most likely to occur.

Check out *CQ VHF* magazine's Propagation column for an in-depth look at propagation on VHF and above. Be sure to send in your reports to this columnist, as well.

Current Solar Cycle Progress

Canada's Dominion Radio Astrophysical Observatory at Penticton, British Columbia reports a 10.7-cm observed monthly mean solar flux of 148.4 for November 2013, up from 132.3 for October 2013, 46 points higher than September's 102.7! This indicates a clear resurgence of solar activity. This provided a lot of great DX and activity even on the 10-meter band. The 12-month smoothed 10.7-cm flux centered on May 2013 is 118.1, up from April's 116.6. A smoothed 10.7-cm solar flux of about 133 is predicted for February 2014.

The Royal Observatory of Belgium, the world's official keeper of sunspot records, reports a monthly mean sunspot number of 77.6 for November 2013, down a bit from October's 85.6, yet still significantly higher than 36.9 for September 2013. The low for the month was 25 on November 26. The high of 131 occurred on November 17. The mean value for November results in a 12-month running smoothed sunspot number of 59.9 centered on May 2013. Following the curve of the 12-month running smoothed values, a smoothed sunspot level of 79 is expected for February 2014, plus or minus 14 points.

The geomagnetic activity as measured by the planetary A-index (Ap) for November 2013 is 5. The 12-month smoothed Ap index centered on May 2013 is a steady 7.0. Geomagnetic activity should be much the same as we have had during January. Refer to the Last-Minute Forecast for the outlook on what days that this might occur (remember that you can get an up-to-the-day Last-Minute Forecast at <http://SunSpotWatch.com> on the main page).

I welcome your thoughts, questions, and experiences regarding this fascinating science of propagation. You may e-mail me, write me a letter, or catch me on the HF amateur bands. Please come and participate in my online propagation discussion forum at <http://forums.hfradio.org/>. If you are on Facebook, check out <http://www.facebook.com/spacewx.hfradio> and <http://www.facebook.com/NW7US>. Speaking of Facebook, check out the CQ Amateur Radio Magazine fan page at <http://www.facebook.com/CQMag>.

I'll be keeping my ears to the radio, hoping to hear you on the air. Happy DX!73, Tomas, NW7US

Oops…

It's all Greek, um, Russian, to us…

Reader Doug Bailey, K0FO, spotted a few errors—mostly in syntax—in our November article on Russian CW. There were a couple of typos in the table of compass directions shown in the original fig. 4 that resulted from "translating" the Cyrillic characters into a form that our computers could read. Corrections are below.

In the original fig. 11, Doug says, *"You translate the phrase contained in the box as 'No please don't reply in Russian at 40 WPM!' It doesn't say that at all. It tries to say, 'Sorry, this is all the Russian that I know.' The Russian word beginning the phrase means, colloquially, 'Sorry' or 'Regrets,' but is more commonly used in common speech when referring to the action of another person as in 'Sorry you're a dimwit.' In the context of this phrase, a Russian would more likely use a word which means 'unfortunately'."*

The "please don't reply in Russian at 40 WPM" line in the caption was an (obviously poor) editorial attempt at humor. The correct English is in the main text. Regardless, a modified form of "Unfortunately, this is all the Russian I know" is provided here as well. Sorry that we're dimwits!

Revised fig. 4, showing corrected spellings of compass directions.

Clarification

In our "On the Cover" column in the November issue, we mentioned that the radio-computer interface used by "cover model" Chris Yody, KE7JBF, was designed and built by the Baton Rouge Amateur Radio Club in Louisiana. We received the following clarification from Dana Browne, AD5VC, one of the interface's designers:

Two members of the Baton Rouge Amateur Radio Club designed the digital interface mentioned in the article. I am one of them. However, we do not build the interfaces for other clubs, despite what the article implies in the last paragraph.

We designed it as a kit building project for our club members. Because of the minimum order needed for the circuit boards, we ordered extra boards and produced unbuilt kits that the club sold as a money-raiser. In fact, the Seattle club that you highlighted bought a large number of kits and then built them themselves.

We are now getting inquiries from hams about having us build interfaces for them, and we have no plans to do that. We may in the future do another kit run, but there is not enough interest yet to make it profitable to the club.

We apologize for any confusion.

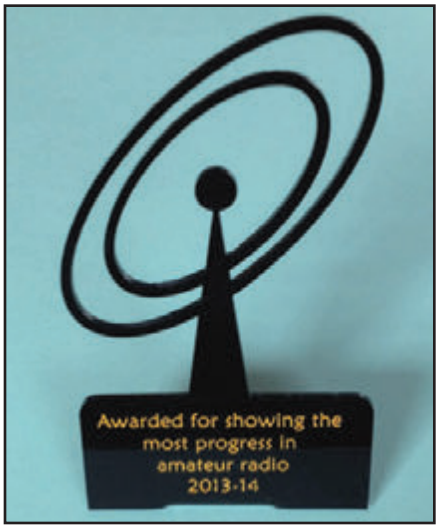
Revised fig. 11, no longer suggesting that anyone (except the editor) is a dimwit!



Club Trophies from SOTAbeams

Richard Newstead, G3CWI, SOTAbeams owner, says that "one of the most common problems that radio club members face is retaining and nurturing the interests of newer licencees. One way in which this might be done is to introduce some club awards. These could be for showing the most progress in the hobby, working the most DX or even for attending the most meetings."

To help clubs in that effort, SOTAbeams has introduced a club trophy that can be custom-engraved The trophy is laser cut from black gloss acrylic and is priced at £4.99 + p&p in the UK, or just over $8US (plus shipping) at current exchange rates. For more information, visit <http://www.sotabeams.co.uk/club-trophy/>.

SpeeCup Bluetooth™ Speaker-Mic

If you have a Bluetooth™-enabled ham rig, you might want to check out the SpeeCup hands-free speaker-mic. Designed to fit in a standard automotive cup holder (thus the name), the SpeeCup will also fit in many bicycle water bottle holders or can just stand on its own. The upward-facing speaker also features "gesture control," which allows you to answer phone calls or change music tracks with a sweep of your hand over the top of the speaker. *(Whether this would work as a PTT control for a Bluetooth-equipped ham rig is probably a function of the rig's Bluetooth circuitry—ed.)* It also has an audio line out jack for connecting to a home stereo, etc., and has been designated as a 2014 honoree in the Consumer Electronics Show Innovations Design and Engineering Awards. The SpeeCup retails for $129.95 and is available directly from the manufacturer at <http://speecup.com>.

The SpeeCup Bluetooth speaker-mic is designed to fit in a car's cup holder or a bicycle water bottle holder.

RF Torque Wrenches from Pasternack

We must admit that our first mental image here was of a wrench designed to allow a precise amount of RF to pass through a connection, but then realized that in critical applications, it is important for RF feedlines to neither be too loose nor too tight, and that's what these wrenches are about.

The PE5019-XX series of break-over torque wrenches allow accurate mating force (measured in "inch-pounds") when assembling and disassembling a variety of RF coaxial connectors. The unique feature of break-over torque wrenches, according to the company, is that they will "break" at the pivot point once the torque value force is achieved, effectively preventing the user from over tightening the coupling nut on the connector. A broad range of break-over torque wrench sizes is available. For more information, visit <http://bit.ly/19SVsxR>.

Two New Product Lines from RFMW

Sunny Electronics *FastClock™* Oscillators: Circuit designers and experimenters may want to check out the new line of Sunny Electronics *FastClock™* crystal and voltage-controlled oscillators, now offered by RFMW, Ltd. The devices offer a wide choice of frequency, voltage and output combinations, and operate from 10–1500 MHz. For more information, visit <www.rfmw.com>.

Florida RF Labs "Lab Flex" Cable Assemblies: RFMW is also supplying and supporting six different types of cable assemblies from Florida RF Labs. The Lab-Flex® assemblies offer >90 dB of shielding effectiveness and a wide range of connectors including, but not limited to, 7/16, TNC, SMA, 2.4mm, 2.92mm and 1.86mm interfaces in various configurations. Standard lengths are 24, 36, 48 and 72 inches. The cables support frequencies up to 65 GHz. For more information, visit <http://bit.ly/GX7C0B> or call RFMW at (877) FOR-RFMW.

WANTED: HAM EQUIPMENT AND RELATED ITEMS. Donate your excess gear—new, old, in any condition—to the Radio Club of Junior High School 22, the Nation's only full time non-profit organization working to get Ham Radio into schools around the country as a teaching tool using our EDUCOM—Education Thru Communication—program. Send your radio to school. Your donated material will be picked up ANYWHERE or shipping arranged, and this means a tax deduction to the full extent of the law for you as we are an IRS 501(c)(3) charity in our 33rd year of service. It is always easier to donate and usually more financially rewarding, BUT MOST IMPORTANT your gift will mean a whole new world of educational opportunity for children nationwide. Radios you can write off; kids you can't. Make 2014 the year to help a child and yourself. Write, phone, or FAX the WB2JKJ "22 Crew" today: The RC of JHS 22, P.O. Box 1052, New York, NY 10002. Twenty-four hours call 516-674-4072; fax 516-674-9600; or e-mail <crew@wb2jkj.org>. Join us on the WB2JKJ Classroom Net, 7.238 MHz, 1200–1330 UTC daily and 21.395 MHz from 1400 to 2000 UTC.

IMRA-International Mission Radio Assn. helps missioners—equipment loaned; weekday net, 14.280 MHz, 1:00–3:00 PM Eastern. Sr. Noreen Perelli, KE2LT, 2755 Woodhull Ave., Bronx, NY 10469.

"World of Keys – Keys III" book features highly detailed views and photos of keys, bugs, and paddles like few people have ever seen ($18)!. Also still available, **"Keys II"** ($16) and **"QRP Romps!"** ($18), plus **"Your Guide to HF Fun"** ($16). Available from dealers nationwide.

PACKET RADIO AND MORE! Join TAPR, connect with the largest amateur radio digital group in the U.S. Creators of the TNC-2 standard, working on Software Defined Radio technology. Benefits: newsletter, software, discounts on kits and publications. For membership prices see the TAPR website: <http://www.tapr.org>).

Capitol Hill and FCC Actions Affecting Communications

Broadcasters and DoD Agree on Sharing 1755-1780 MHz

U.S. House Energy and Commerce Committee Chairman Fred Upton and Communications and Technology Subcommittee Chairman Greg Walden, W7EQI, say that they welcome the National Telecommunications and Information Administration's endorsement of an agreement between the Department of Defense and the National Association of Broadcasters on the relocation of a parcel of government spectrum to shared use.

The agreement was reached after bipartisan committee leadership worked with the Department of Defense, the National Telecommunications and Information Administration, and the Federal Communications Commission. It paves the way for the Department of Defense to move systems out of the 1755- to 1780-MHz band by creating a sharing arrangement between it and the broadcast community in the shared use of the Broadcast Auxiliary Service.

This spectrum is used by news organizations to originate material such as breaking news stories from outside of studio facilities. *(**FULL STORY:** <http://1.usa.gov/18yxltt>. – KI6SN.)*

Kansas Radio Amateur Nabbed As FM Broadcast Pirate

Glen Rubash, KCØGPV, of Dwight, Kansas, has been hit with a $4,000 Notice of Apparent Liability for operating an unlicensed FM transmitter on 88.3 MHz in the city of Manhattan.

The fine had originally been issued for $15,000 but was reduced after Rubash produced documentation showing his inability to pay.

The FCC said Rubash admitted over the telephone to its agents that he installed and owned the station's radio transmitting equipment. According to *Amateur Radio Newsline* (ARN), "he also demonstrated control over the station by stating that he would refuse to surrender the equipment to the agents from the Kansas City Office if required to do so."

The FCC said that "even though Rubash admitted via telephone interview to making the admissions, he later asserted that his statements were based on incorrect information ... In his written response he stated he owned and installed a low-power FM radio transmitter but that it operated within Part 15 unlicensed limits."

In denying most of Rubash's requests, the FCC said it affirmed the NAL, finding he violated Section 301 of the Communications Act by using equipment without the required Commission authorization.

More Musical Chairs at the FCC

Communications attorney Roger Sherman is the new Acting Chief of the FCC's Wireless Telecommunications Bureau, which oversees amateur radio as well as other two-way radio services. Sherman replaces former Bureau Chief Ruth Milkman, who was named Chief of Staff to new FCC Chairman Tom Wheeler.

According to the ARRL, Sherman previously served as the Democratic Chief Counsel to the House Committee on Energy and Commerce, along with other Congressional staff positions.

Oklahoma CBer's Linear Amplifier Brings $15,000 Fine

The FCC has issued a $15,000 Notice of Apparent Liability for Forfeiture to Carlton Lewis, of Enid, Oklahoma, alleging he operated a Citizens Band radio with an external power amplifier in violation of Part 95 rules.

In May 2013, agents from the Enforcement Bureau's Dallas office tracked down a strong signal on 27.1850 MHz — CB Channel 19 — coming from Lewis' residence.

For more than 30 minutes, no one answered an FCC agent's knock at the door. Ultimately, Lewis appeared and showed the agent his CB transmitter, which was warm to the touch.

According to an ARN report, "the agent observed that no coaxial cables were connected to the CB transmitter but also noted the coaxial cable coming into the residence and traced it to a linear amplifier hidden behind a sofa. The linear amplifier was also warm to the touch. Lewis did not respond when asked whether he had used the linear amplifier."

Prior to his most recent citation, the FCC noted Lewis' CB station had been issued two warnings from the Dallas Office, advising him that an amplifier voided his authority to operate. Based on previous experience, the FCC ruled a $15,000 fine was warranted.

Commission Upholds Fine for Marketing Unauthorized RF Devices

The FCC has issued a monetary forfeiture in the amount of $14,000 to Custom Interface Technologies, a Division of Thornstar Corporation, in Joshua Tree, California for "willfully and repeatedly violating rules against manufacturing and marketing of unauthorized radio frequency devices in the United States."

The company, alleged to have marketed uncertified video assist transmitters, told the FCC it did not have the ability to pay the $14,000 fine. "However in affirming the forfeiture amount the FCC says while Custom Interface Technologies did provide the Commission with three years of tax returns and a bank statement to support its claim of an inability to pay, after review of these financial documents that the FCC declined to reduce the forfeiture amount and that "the $14,000 fine is warranted."

There is good news for broadcast band DXers who like to listen to more than just a station's callsign and city at the top of the hour. Top radio industry execs say 'live and local' are making a comeback …

CQ Plus Reports: 'The Power of the Microphone'

BY RICH MOSESON, *W2VU

Broadcast-band DXing was my first love in radio. In addition to the thrill of tuning in faraway stations, I was captivated by hearing about what was going on in those other places – the local news, the local commercials, the challenge of trying to figure out where the station was before hearing the ID at the top or the bottom of the hour.

The voices coming through the speaker into my bedroom drew me in . . . into radio as a hobby and into a career in radio, television and print journalism. It all started with those voices.

In recent years, though, the uniqueness of local radio has in many places given way to homogenized programming and shows delivered by satellite from New York or some other big city. Now, satellite radio is even taking local radio stations out of the equation, along with Internet "radio" sources such as *Pandora* and *iHeartRadio,* which lets listeners eliminate those voices altogether and simply package music that is sent over the Internet to your smartphone or even your car.

The Tide is Turning

Good news. "Terrestrial radio" is fighting back. And it is sending to the front lines the DJs and news reporters who

Photo B. *Newhouse School of Public Communications Dean Lorraine Branham said her advisors told her to call the session an "audio" industry summit because "radio" was too limiting. "But it's all about radio," she said in opening remarks.*

made broadcast radio such an important part of so many American communities, but who, in recent years have frequently been marginalized.

"Radio is not about music," CBS Radio President Dan Mason told an Audio Industry Summit in late September. "Radio is not about news, or traffic or sports. Radio is about the power of the microphone."

His feelings were echoed by Bob Boilen, host of "All Songs Considered" on National Public Radio. "I want somebody to talk to me," he said. "I want a storyteller. That's what I want out of the medium ... That's where radio wins."

The summit was organized by Syracuse University's Newhouse School of Public Communications and held at Lubin House, the university's "outpost" in New York City[1], **Photo A.**

Newhouse Dean Lorraine Branham, **Photo B,** opened the event by discussing her memories of growing up listening to the radio in Philadelphia, and pointed out that the meeting was being called an "audio industry summit" because "my advisers told me 'radio' was too limiting." Then she paused and added, "But it's really all about radio."

About 100 people attended[2], including two groups of panelists. Most were top executives of various media companies and, in a reflection of where we continue to be as a society, the group was overwhelmingly male, white, and over 50.

The first panel, **Photo C,** was supposed to discuss the current state of the radio industry and the second, **Photo D,** was supposed to look at its future, particularly in the face of competition from satellite and Internet radio "disruptors" such as Pandora and iHeartRadio (both of which were represented on the second panel). But they kind of got all that mixed up and both groups talked about both the present and the future.

Live and Local

The first panel was made up of executives of radio stations or station groups, including CBS Radio's Dan Mason, **Photo E**; Patrick Walsh, CEO, COO and director of Emmis Communications, which is one of 10 biggest radio station owners in the country; Deon Levingston, Vice President and General Manager of WBLS in New York City, **Photo F**; Buzz Knight, in charge of programming development for Greater Media and former Program Director of various stations, including the iconic WNEW-FM in New York; and Ed Levine,

Photo C. *The first of two panels was made up of top executives of traditional radio stations or station groups. (See text for a "Who's Who")*

Powerhouse WABC Radio Makes Shift to 'Local'

New York City's WABC-AM 770 is making dramatic changes to its talk radio line up, with a greater emphasis on "local" hosts and issues. Details:< http://www.CQPlusDigital.blogspot.com >.

Photo D. *The second panel, on radio's future, included a mix of people from "terrestrial" radio and Internet-based radio services.*

President and CEO of Galaxy Communications, which owns 14 radio stations in upstate New York.

All of the speakers were very positive and upbeat about the state of the radio industry and its future, with an emphasis on the need for radio stations to return to being "live and local" in order to set them apart from satellite and Internet competition. "Local is our job," said Levingston. Knight said his company is "now seeing the importance of good content and good personalities," citing the midday DJ at his company's station in Philadelphia – Pierre Robert – as "the heart and soul of Philadelphia."

Walsh echoed the theme of bringing the "local" back to local radio, while acknowledging that the two largest radio station groups in the country (Clear Channel and Cumulus) do not yet share that vision. But as far as his company is concerned, Walsh said, "Strategically, local makes sense, it's where our growth is. Our personalities drive us." And he added, "Being local is what differentiates us, what makes us special and different ... that connection with the listeners."

This attitude should come as welcome news to broadcast-band DXers, who should once again be able to reap the benefits of listening to uniquely local programming as they spin the dial, seeking out new stations in faraway places.

Photo E. *CBS Radio President Dan Mason told the group that radio is not about music, news or sports, but rather about "the power of the microphone."*

Photo F. *Deon Levingston, Vice President and General Manager of WBLS in New York City, noted that "local is our job."*

Goin' Mobile ...

A few years back, I wrote a guest editorial in *Popular Communications* about missing my transistor radio and lament-

ing that I couldn't listen to the baseball playoffs while shopping at my local supermarket[3]. Well, that topic also came up, with Walsh pointing out that the radio industry has recently put together an "app" that activates an FM receiver on some Android phones offered by Sprint. "On average," he noted, "people look at their phones 156 times a day, or every six minutes." Or as Mason put it, "the cell phone has become the new transistor radio."

WBLS's Levingston welcomed that development, noting that in recent years, "as an industry, we've lost our portability." He pointed out that there were three distinct stages of technological development in broadcast radio, starting with the home console radio that plugged into the wall. The next big leap was into cars in the 1930s and '40s, followed by the introduction of the battery-powered transistor radio in the '50s and '60s. But the last portable radio with any popularity, he pointed out, was the Sony Walkman in the 1980s. "This app," he said, "will help us regain our portability."

Car radios are now doing more than just playing music, and that was part of the focus of the second panel, which included representatives of the "disruptors" as well as traditional broadcasters. Along with "mobile devices" (smartphones, for example) getting radios, car radios are beginning to provide for Internet information sources, such as Pandora or iHeartRadio. And, just as the frequency display on your scanner or ham rig has now become a multifunction display providing a variety of information, so are car radio displays now offering station, song, and artist readouts as well as album art and other visual information.

Photo G. *Kevin Straley of TuneIn discussed the fact that after the Boston Marathon bombing, his service's listeners "tuned in" to Boston police scanners as much as they did to local and national news sources.*

Speakers on the second panel included Chris Oliviero, Executive Vice President of Programming for CBS Radio; NPR's Bob Boilen (introduced earlier); Owen Grover, vice president of "content partnerships" for Clear Channel Entertainment and a co-developer of iHeartRadio; Tommy Page, vice president of artist and brand partnerships at Pandora; Kevin Straley, VP of programming at TuneIn; and Ryan Delaney, a news reporter for public radio station WRVO, a 2010 Newhouse School graduate and token "young person" on the panels. The moderator was Doug Quin, a professor at the Newhouse School and do-director of its audio arts department.

Grover, Page, and Straley emphasized they consider the newer, Internet-based, entertainment media to be *additive* to traditional terrestrial radio rather than competitors, providing listener-controlled programming.

"I believe Pandora is the future," said Page. "The future is streaming, and small artists. Multiple platforms encourage new and small artists." He noted that the iPhone had prompted exponential growth in Pandora. "Two years ago, 80 percent of our listeners were on desktops. That's now reversed, but with no loss of the desktop audience. It has all been growth on the mobile side."

Grover, however, pointed out that radio over IP is still very young, reaching only 50 percent of the U.S. population, while streaming video already reaches 90 percent. "There is a lot of room for growth," he noted.

Not Just Broadcast

One aspect of the growth in radio over IP that should be of interest to many *CQ Plus* readers is that the medium is not restricted to music or even to broadcast radio stations. TuneIn's Kevin Straley, **Photo G,** said that in the aftermath of last spring's Boston Marathon bombing, "TuneIn had links with WBZ news radio, WRKO talk radio, CNN for a national perspective, and Boston police scanners . . . which rated as high in listenership as the national media sources."

Straley later said that "radio is just one part" of what TuneIn offers," noting that "we have more than 70,000 live streams, including scanners and FAA airport towers."

Indeed, when clicking the "local" tab on TuneIn.com's website from my home computer in northern New Jersey, the menu of choices included not only all of the FM, AM, and HD broadcast stations in the metro New York area, but a wide variety of amateur radio repeaters and public safety agencies as well.

Personal Connections

The overall emphasis of all the speakers – whether representing traditional broadcasters or Internet-based sources – was the necessity of engaging individual listeners. The Internet radio people see that as coming through providing listeners with individual control of what they hear, while the broadcasters are focusing on the personal connections and community involvement that come with the return of live, local disk jockeys.

"We want the DJ to once again be the biggest star in town," said CBS's Olivieri.

"Radio stations have always had the reputation of calling people to action," noted his boss, Dan Mason, while Clear Channel's Owen Grover later echoed that thought, saying, "My colleagues truly plant beacons in the center of tribes." But, these radio industry leaders are learning, those beacons are only jukeboxes if they don't use "the power of the microphone."

*(**LISTEN:** To a 2-hour, 45+ minute podcast of the Audio Industry Summit at <http://bit.ly/16HcJOE>. – W2VU.)*

Notes:

1 - The city of Syracuse is 250 miles from New York City, yet many of Syracuse University's students come from and return to the New York City area. Since 1965, the university has operated Lubin House as its "remote base" in New York City, featuring events for alumni, current, and prospective students. To learn more, visit <http://lubinhouse.syr.edu/>.

2 - The summit was also streamed live on SU's student radio station, WERW, making it accessible in real time to Newhouse students at the main campus in Syracuse. A podcast was also posted for later listening at <*http://bit.ly/16HcJOE*>.

Digging Into Specifics of the Commission's 'Revitalization' Proposals

The FCC Moves to 'Fix' AM Broadcasting

BY ROB de SANTOS, K8RKD

This extended version of *Horizons* explains the recent FCC Notice of Proposed Rulemaking (NPRM) regarding the U.S. AM broadcast band and what it might mean for medium-wave broadcasting in the United States.

We've been covering the changes affecting the AM broadcast band for well over a year now.[1]

An AM Haze and Malaise

It's no surprise to many of us that the AM band is suffering badly from neglect and declining numbers of listeners, **Photo A**. After nearly 18 months and on the doorstep of a new leader at the FCC, a NPRM was issued on October 31, 2013 laying out the plans for the future. *(IN DEPTH: See FCC NPRM 13-139: "Revitalization of the AM Radio Service" at <http://fcc.us/18UO2xm>, Photo B. – K8RKD.)*

The FCC has proposed to make a number of changes, some that will be popular, and others likely to be controversial even among station owners and managers. It has not opted, at least for now, to go along with some of the more radical proposals including moving AM broadcasters to an expanded FM band or taking the band to entirely digital. With these choices off the table, it remains to be seen if what is now proposed will have the desired effects on the AM band.

As I've noted in earlier columns, listeners to medium-wave or AM broadcasting in the U.S. have declined radically over recent decades. As late as the mid-1970s the majority of all radio broadcast listening in the United States, and indeed worldwide, was in the AM mode — not FM. Today, by some measures, the band garners less than 10 percent of all listening hours in the U.S. and with the advent of digital services, that decline is accelerating. Among the youngest demographic sectors, the band is almost completely ignored. In the NPRM, the FCC noted that only 4 percent of listening time among those aged 25-34 was to AM.

Among the other issues facing AM, these include increased interference and low fidelity. The interference increase is due to several factors including the proliferation of more and more electronic and computerized devices, slack enforcement of the FCC's own standards for interference, the overlay of digital services on the band, and the changes in the FCC rules allowing higher power and extended hours for many stations.

It's No Longer the 1930s

What makes AM effective as a means to reach wide geographic areas

Photo A. *FCC proposals may bring big changes to AM radio across the United States. This Victor Model 3-RF-91 AM-FM radio was found by a lucky looker at a yard sale. After a bit of tender-loving care, it works and looks great. "This thing has an 8-inch speaker and sounds fantastic," writes the photographer. It may be hearing a whole new type of medium wave if all the FCC proposals are adopted. (Courtesy of AlexKerhead via Wikimedia Commons)*

email: <commhorizons@gmail.com>
Twitter: <@shuttleman58>

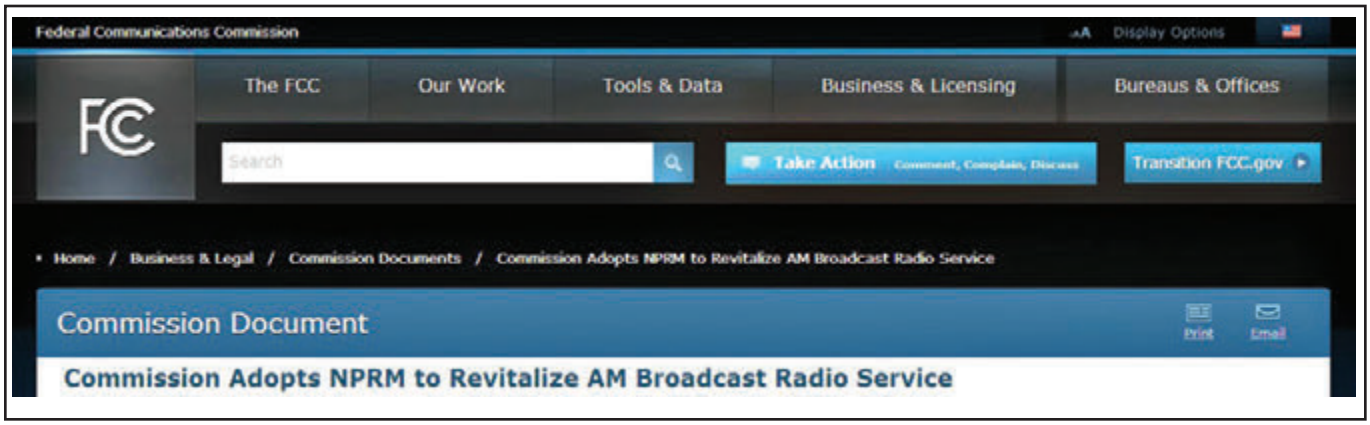

Photo B. *The full text of FCC Notice of Proposed Rulemaking (NPRM) 13-139, regarding U.S. AM radio, can be found at "Revitalization of the AM Radio Service" at <http://fcc.us/18UO2xm>. It can be viewed as a Word, PDF, or text document. (Internet screen grab)*

at night also makes it subject to nighttime interference. The low solar cycles haven't helped either as skywave propagation at night has suffered. While DXers and radio lovers might not be happy with the past changes to the AM band, the country is a different place than it was in the 1930s when the basics of the AM band plan were first fixed and "clear channels" set by regulation and treaty.

It was a reasonable assumption in 1934 that having a few stations that could be heard by most of the country provided a guaranteed communication backbone for the U.S. Many local stations back then could not have afforded to be on the air well into the night even if they were permitted to do so. Those assumptions may no longer be true.

Judging from the programming on many of the remaining stations with "clear channel" frequencies, the station programmers no longer think it important to cater to 30-or-more states at night and only to their local audiences even if they occasionally acknowledge others are hearing them.

Changing Technologies

With satellite and fiber distribution of programming, listeners in remote areas can be reached in emergencies without necessarily needing clear-channel stations. State emergency radio networks now reach every geographic corner of their territory in many cases. The advent of the Internet has made it possible for very low-wattage stations to be heard worldwide.

Changes in music listening and the growth of talk radio have also had an impact. FM brought static-free sound to audiences and imaginative programming saw migrations of listeners begin to move away from AM in the 1970s.

The number of AM stations in the U.S. has declined by an average of nearly 10 per year since 1990 while the number of FM stations has doubled. There are now more than three times as many FMs as AMs. Despite actions by the FCC in 1990-91, 2005, 2006, 2008, 2009, and 2011, the tide has not turned. The emergence of highly popular syndicated talk radio in the mid-1980s briefly seemed to save the band but now those very talk formats are increasingly moving to FM.

Specifics: What the FCC is Proposing

The NPRM contains at least six major changes. Some of them are highly technical adjustments that matter mostly to stations' engineers and owners and others have more broad impact. I'll try to give you a simplified explanation of each and what it means to hobbyists and listeners.

FM Translator Expansion

The agency has proposed to open an exclusive window for AM station owners to apply for new FM translators. This window would be open after the FCC has concluded processing the recent applications for low-power FMs for community and non-profit applicants and disposed of the thousands of remaining applications for FM translators from current FM station owners. ***(NOTE:*** *Some of the latter have been pending for many years. – K8RKD)*

There are some unique aspects to this particular proposal. The most important is that it would be restricted to current station licensees and permit owners and the translator could not be sold except with the primary station license.

The translator would be permanently linked to the primary AM station. In addition, the coverage area of the translator must be the smaller of either the station's primary daytime coverage area (2mV/m contour), or a 25-mile radius of the current transmitter site. ***(IN DEPTH:*** *See the accompanying "What Does mV/m Mean?" – K8RKD.)*

For many lower-power AMs or those with limited or no nighttime service, they would now be able to serve their primary market 24 hours a day.

Reduced Daytime Coverage Standards

One of the issues facing many commercial AM station owners, particularly those in highly urbanized environments, is that making any change to your transmitter site or antenna system that would improve listening for the majority of the audience or the stations market potential is not possible.

If the change reduces coverage of the primary city of license below 80 percent of either the population or area, whichever is higher (5mV/m contour for the techies), it will not be permitted.

The FCC has proposed to change the standard to be similar to that in effect for non-commercial stations: 50 percent of the population or 50 percent of the area the community of license at a minimum of 60 dBm – decibels per microvolt of signal strength.

Photo C. *"The interference-free contour means that many stations on a given frequency have a minimum protected area on that frequency," K8RKD writes. "For example, for clear-channel stations such as 1030 WBZ in Boston this can be half or more of the U.S., Canada, or Mexico." (Internet screen grab <http://cbsloc.al/1cNmZmG>)*

It is possible that any future waivers of the existing standard would also be eliminated. For readers, this would certainly affect the behavior of stations for DXing and casual listening purposes. Many stations would become unlistenable in some local areas while others would immediately become DX opportunities due to the facility improvements.

Station owners would gain considerable flexibility in making transmitter and power changes.

Nighttime Coverage Standards

Many AM stations have different antenna or different transmitter sites in order to meet the different technical requirements for daytime and nighttime service.

What's Does mV/m Mean?

The formula mV/m stands for milliVolt per meter and is a measure of the strength of the electric field at a certain distance.

Simply, if there is a voltage difference of 1 Volt and the two places you are measuring are 1 meter apart that is a strength of 1 V/m.

When talking about radio waves, the electric field varies inversely with distance. This is a one-dimensional measurement and it only varies by the inverse — *not* the square of the inverse. Double the distance and the electric field is half as strong. One hundred times the distance and one-hundredth the radio wave field strength.

The best way to view this as a listener is to think in terms of what your radio is capable of picking up. A typical car radio should be able to pick up any station which meets the 2mV/m standard for your listening point — local noise levels notwithstanding. – *K8RKD.*

As many readers know, AM propagates as groundwave during the day and skywave at night. Skywave propagation is similar to shortwave propagation while groundwave is limited by distance, geography, and power. *(**IN DEPTH:** In skywave propagation, signals reflect off the ionosphere and can be heard at great distances <http://bit.ly/1fZgToo>. – K8RKD.)*

During the day, stations must meet the aforementioned 80 percent coverage requirement. At night, there is the additional requirement that the signal cannot breach the guaranteed interference free contour of other stations.

The interference-free contour means that many stations on a given frequency have a minimum protected area on that frequency. For example, for clear-channel stations such as 1030 WBZ in Boston, **Photo C**, this can be half or more of the U.S., Canada, or Mexico. As such, other stations are thereby limited to their local market and nothing else. As you might guess, with skywave propagation, that is a tall order since the signal might bounce off the ionosphere and be heard several states away.

The FCC has proposed to modify the 80 percent rule. The FCC is proposing that stations be required to serve only 50 percent of their area or population, whichever is higher, (nighttime contour again) but still be subject to the non-interference rule.

Eliminate the 'Ratchet Rule'

The 'Ratchet Rule' regards a more technical requirement which affects higher power AM stations — in FCC parlance, Class A and B stations. The current rule requires AM stations to reduce — or *ratchet back* — their power levels such that it reduces skywave interference to other stations on the same frequency if they apply to make any facility (transmitter, power, antenna, etc.) changes to their license.

Icom has the receivers for the experts...

IC-R9500 The Ultimate Wide Band Receiver

- 0.005–3335.000MHz*
- USB, LSB, CW, FSK, FM, WFM, AM
- 1020 Alphanumeric Memory Channels
- P25 (Option UT-122)
- Five Roofing Filters and so much more!

AND for those on the go!

This rule was part of the FCC changes made back in 1991 when the band expanded adding channels up to 1710 kHz. The intent was to reduce interference. However, the FCC has now concluded it hasn't worked as intended.

Various petitions submitted to the FCC have argued the rule does, in fact, discourage stations from making improvements since any facility change such as transmitter relocation, antenna pattern change, and so on, mean the station must reduce its power to comply with the rule.

The result is a loss of interference-free service at night at minimal benefit to other stations. The stations most disadvantaged by the rule are those which are the oldest on the air while newer stations already accepted the interference conditions when they went on air and thus get little benefit.

The FCC has proposed to delete the rule entirely. For listeners outside the station's primary area of service, this might not have much impact. It won't reduce the interference-free zones of other stations on the same frequency. Their protection is retained. If anything, it will improve the quality of some stations heard at night outside their primary coverage area and have some marginal reduction in DXing of weaker stations on the same channel.

Modulation Dependent Carrier Level Control (MDCL)

MDCL is another very technical change. At present, with only a few dozen exceptions by waiver or experimental permit, broadcasters generally do not vary the power of the carrier frequency or the sideband as modulation is changed.

To do so would result in the input power to the antenna below levels permitted under FCC regulations. The FCC is proposing to permit carrier and sideband power to vary with modulation — generally, full/higher power maintained at low modulation and reduced power at higher modulation.

For station owners this could mean reduced costs due to lower power consumption by the transmitter. The FCC would permit stations to implement MDCL without prior FCC authorization and do so even if they provide hybrid (analog and digital) service.

If all of that means nothing to you, don't worry. Since only a few dozen stations have tested this. It is too early to say what it would mean for listeners, if anything. A few critics of poor AM signals would probably welcome a change that reduced modulation as it might improve the sound of some over-modulated stations.

Modified AM Broadcast Antenna Requirements

Currently, the FCC requires that any AM station seeking to make a change to its facilities, transmitter, and so on, must ensure that the new installation still meets the requirements for the class and power levels of their license. This is quite reasonable.

In practice, the station must demonstrate that either the antenna is of a certain minimum height above the surrounding terrain or its effective signal strength meets the minimums over its service area.

The FCC has proposed a 25 percent reduction in the minimum field strength requirements for each class of AM stations, which would provide more relief and flexibility to station owners to make station modifications. For fringe listeners, this might mean less service but it could also mean better service for the primary market if the newer antenna and transmitter system is of higher quality.

What and When

The NPRM requests extensive comment from the radio industry and public and it is quite possible that one or more of these proposals will change significantly before they are implemented by the Commission.

At this writing, the timetable is still a bit fuzzy. But barring extensions, the comment and reply period will have closed in late January 2014. We can then expect that the FCC will take some time to process all of the input and another NPRM or a Final Report and Order may be forthcoming by the middle of 2014.

These proposals largely address technical and financial concerns of station owners, managers, and engineers. They do little to address the fundamental market issues driving the decline of the band.

At best, they buy time for the radio industry to settle on and propose changes that are more radical. Even if interference is reduced and signal quality and reach enhanced, it is hard to see how these changes will result in stabilizing the band and preventing further declines in the longer term.

What is Your Reaction?

Listeners and DXers have quite a bit to consider here, too. It's time to think about what we want from the band going forward. If you have ideas, write to the FCC and your congressional representatives and let them know. Also, let us know.

Which of the proposals should the FCC adopt? Is it even possible to save the band at this point? What does it mean for your DXing? Share with me your reaction. Write to me via the magazine, or drop an email. We'll publish some of your thoughts in a future article. More on the future of communications in *Horizons* next month.

– K8RKD.

BY RANDALL NOON, KCØCCR

For Valentine's Day: Romancing the Key — A CW Love Story

Computer-generated digital modes require a keyboard with 104 buttons or more — most with more than one function — that have to be touch-memorized in order to enter messages competently into a transmitter.

Computer-generated digital modes then require a matching decoding program at the de-modulation end to convert the digital message into clear copy. Compare this to Morse code, requiring only one button and a trained ear. *Simple.*

When band conditions are poor, a message sent in CW can get through when the same message sent by single-side band (SSB) phone, amplitude modulation (AM) phone, frequency modulation (FM) phone, or RTTY cannot. To match the good signal-to-noise ratio of a modest 5-watt CW signal, an SSB phone signal needs more than 100 watts. *Practical.*

Morse Code also has an inherent rhythmic, musical quality. To some, it sounds pretty. Like a songbird. There are:

- Triplets, such as the letters *S* and *V* and number *3*
- Syncopations, like the letters *C, L, F,* and *Q*
- Short, rhythmic drum patterns, such as the comma, question mark, the letter *H* and the number *5*

In other words: *Musical.*

She: Betty Broome, VE3ZBB

Allow me to add one more Morse code descriptor to the list: *Romantic.*

The explanation of this adjective begins with FISTS member No. 1265, Elizabeth Broome — otherwise known on the air as VE3ZBB.

(**BACKGROUND:** VE3ZBB was instrumental in providing background to this story, along with *The Canadian Amateur*, which carried her story in 1998/ – KCØCCR)

FISTS is another name for the International Morse Preservation Society with more than 16,000 members worldwide. Elizabeth, or Betty as friends call her, earned her Canadian ham license in March 1988. She was the first and only one in her family to hold a license. In 1993, Betty became a member of FISTS.

As many do, Betty started using a hand key, then switched to using paddles, and now uses either one. She enjoys working CW on all the bands, but favors 30 meters, the only all non-phone band, and is not on voice at any time on HF.

When possible, Betty likes to work CW newcomers and encourage them by sending at a word-per-minute speed comfortable for them, no matter how slow. Like the FISTS motto: *when you work VE3ZBB, you have worked a friend.*

He: Rod Newkirk, W9BRD

On August 28, 1991 at 19:58 hours UTC, according to her log, VE3ZBB worked W9BRD on 30 meters at 10.107 MHz. Recalling that QSO, Elizabeth noted that, "for some reason, I knew at that moment that this radio operator was special."

The call W9BRD belonged to Rod Newkirk, an extra-class operator who lived in Chicago. As Betty recalls, "when Rod sent code it was beautiful to listen to and to copy."

Remembering Their Chance CW Meeting

Betty recalls that at first they exchanged signal reports and typical information. Despite poor band conditions that day, they drifted naturally into a lively CW conversation. Rod told Betty that he had been retired for four years and he was, "reliving his teen years with no responsibilities at all, *so you better watch out, lady."*

He said he'd been a widower for 17 years and mentioned to Betty he "... no longer signed any contracts." Rod was enjoying the best retirement hobby of all, he said. Unfortunately, the band kept fading. Finally and reluctantly, VE3ZBB and

Betty Broome, VE3ZBB, and Rod Newkirk, W9BRD, visit Glencoe Beach during their Chicago "first meeting" in 1993.

e-mail: <rknoon@nppd.com>

Mr. and Mrs. Newkirk, married June 27, 1997.

W9BRD had to say *73* (best regards) and end the contact after struggling to keep the conversation going with an uncooperative 10.1-MHz band. Betty hoped they would meet again on the bands. Over a half-hour had passed during their enjoyable CW banter.

As is often said, *and is true*, the final courtesy of a QSO is the exchanging of QSL cards. Betty and Rod were nothing but courteous. They also exchanged pictures. Rod sent along a letter to explain why his QSL had been delayed. It was sufficiently entertaining that Betty shared it with her husband, son, and daughter-in-law.

Rod Newkirk at his and Betty's Yaesu FT-1000. Note Betty's bulletin board with photographs above the transceiver.

Rod's photograph was put on Betty's bulletin board above her transceiver with many other photographs that other operators had sent to her over the years. She listened for his callsign to pop up again on the bands, but did not hear it.

Comfort in Loss via Amateur Radio

In March 1992, Betty lost her husband of 42 years. Adjusting to a new and different life is difficult after 4+ decades. Betty found free time hard to come by. However, amateur radio was a comfortable place where Betty could spare a few minutes now and then with both old and new on-the-air friends. She said it was, "an escape into another world, and an extremely pleasant one."

Almost a Year Later, Love is in the Air(waves)

On July 30, 1992 at 21:25 UTC a little CW magic happened. On 30 meters (10.107 MHz) Betty sent *CQ.* She again heard W9BRD's excellent Morse answer — big surprise! She replied right away. As Betty recalls, "Here again was the person I'd had such an enjoyable CW conversation with 11 months ago."

During the subsequent QSO chat, Rod told her that from time to time he had heard her on the bands, but that she had been busy with another operator. Betty shared with Rod her recent loss.

Since Rod had been through a similar rough patch, he well understood what was going on in her life. The reunion QSO lasted 45 minutes. This time, though, just before the 30-meter band dropped out, they agreed to a weekly schedule on Thursdays.

On-Air Date: Every Thursday ... and Monday

Betty recalls that she looked forward to the Thursday QSOs. Later, a Monday schedule time was added because, as Rod said, "Thursdays only weren't enough."

Soon, they began exchanging letters and telephone calls. In her first letter, Betty mentioned to Rod that he should have been a writer because she enjoyed his letters so much. Rod must have had a fun time telling Betty, who had not been a *QST* reader, that he had been a writer for the American Radio Relay League — having written *QST's* "How's DX" for more than 30 years.

Betty discovered, among many things, that Rod had been a ham since 1937. In earlier years, he had been a contester

Rod sends code on Betty's Heathkit HW-9 QRP transceiver at Green Lake Cottage.

VE3ZBB and VA3ZBB — t'was a wonderful life ...

and had also attained DXCC. Of the many certificates, Rod had achieved 55 wpm CW proficiency from the ARRL. He used a Vibroplex or Bencher paddle for CW, and sometimes used a straight key.

He still liked contesting and knew where to look for exotic stations. Often he was the first to answer their CQ, and then came the pile up. In his later years, however, he gave up contesting and simply enjoyed spending time on the bands making conversation and snagging a DX station or two.

With the increased frequency in CW QSOs, letters, and telephone calls, it was obvious to just about anybody — but perhaps *them* — that Betty and Rod had moved out of the narrow, friendship sub-band into a wider mode. Both Betty's and Rod's families encouraged them to meet.

They Meet in Chicago; Marry in *Shangri-La*

Betty traveled to Chicago in the spring of 1993 and the two CW aficionados finally met — one and a half years after that first CW QSO.

Rod and Betty became engaged in November 1994. Rod became FISTS member No. 7672 on June 1995, and the couple was subsequently married on June 27, 1997 in Ottawa, Canada. Rod was 75 and Betty, 68. *Rod and Betty (Broome) Newkirk*.

Rod subsequently moved to Ottawa, parked his keys and keyers in front of their shared transceiver, and christened their Ottawa cottage *Shangri-La.*

Betty recalls Rod could send code on any type of key, and even made one of his own on a simple wooden board. He was interested in indoor antennas and tested his new ideas in their radio room.

"Our radio room always had some kind of structure set up in it," Betty said, "and he tested each antenna individually, kept records of his designs along with construction details and eventually the contacts he made with them."

Rod became a Canadian citizen, studied and took the Canadian amateur radio examination, and was rewarded with the callsign, VA3ZBB. Sometimes this caused a bit of fun confusion when operators called Rod, Betty, and vice-versa. *They had a wonderful life together.*

Never Ending Stories

Rod continued to write and contributed to the *K9YA Telegraph E-Zine,* at <http://www.k9ya.org>.

Some of the pieces Rod wrote were gathered into *The Rod Newkirk Collection,* which was printed and bound by Lulu <http://www.lulu.com>. It is still available.

As noted by a reviewer, "Rod Newkirk joined the K9YA Telegraph staff in September 2004 with the publication of his story, '*A QSO with CRØOK*.' That first, short article about a legendary Chicago gangster and his predilection for Morse code set the benchmark for the 44 articles to follow."

Rod Newkirk, VA3ZBB (SK)

Sadly, VA3ZBB passed away November 19, 2012 after spending more than three years in the hospital following a stroke.

Betty visited him every day — sometimes two and three times a day. While his left arm was affected by the stroke, his mind was keen and his right hand was still able to operate a key. Betty, however, was not allowed to set up a transceiver in the hospital.

T'was a Wonderful Life

Betty and Rod shared a life that began with a just routine CW QSO. *A wonderful life.*

As Betty noted in *The Canadian Amateur* in February 1998, "Morse code telegraphy is a unique form of communication between two people ... My special way of expressing it would be an invisible thread that ties two people together."

Epilogue: Betty is on the air again and has a new Cushcraft R9 antenna that is working great. Check 30 meters for her CW CQ.

Simple, practical, musical, and even romantic. CW is so cool.

Acknowledgements

Background for this article was gathered from *The Canadian Amateur,* February 1998; page 35.

The Rod Newkirk Collection, by Rod Newkirk, published by the K9YA Telegraph, Robert F. Heytow Memorial Radio Club, is copyright 2011, and contains a story about Betty and Rod. A nice photograph of the two of them is on page 8. The book, by the way, is a fine read. I recommend it.

A personal *thank you* goes to Nancy Kott, WZ8C, FISTS Coordinator who remembers everything and helped kickstart this story. *73, Randall, KCØCCR*

A Big SWL Shuffle for Radio Miami International

Strange twists are occurring in the shortwave world. In the midst of shutdowns, closures, permanent sign offs, penny-pinching governments, and other program producing organizations discontinuing operations, comes an odd situation.

Well-known broadcaster Radio Miami International has shut down its operations from Miami (on 9955). But not to worry, programming will immediately resume from the facilities of the former WYFR. In short, a mammoth turnover has taken place.

WRMI's single-frequency operation has instantly become one of the big boys, with access to Family Radio's 13 high-power transmitters — feeding 23 antennas — providing worldwide coverage.

The "new" WRMI will continue to carry Family Radio's programming for South America and the Caribbean and will add programming from Pan American Broadcasting, normally heard on 15190 from Equatorial Guinea. *Whew!*

That's what you call a "bombshell." Good luck to Jeff White and WRMI. Hopefully he'll have many, many years of successful operations from Okeechobee!

<gdex@wi.rr.com>

REE Relay Station Closed in Latin America

Radio Exterior de Espana has closed its relay station at Cariari, Costa Rica. *Now why would it do that?*

Your guess is as good as mine. REE didn't give us an explanation, but it was probably a money-saving move, although REE *does say* it will try to make up the decrease in coverage by upgrading its main (read that *only*) other facility at Nobeljas, Spain.

Here are three segments of the giant, multi-part QSL Ralph Perry received from the Voice of Han in Taiwan. Top that one for splendor if you can!

The Costa Rican facility has been around since it opened in October 1992.

Pirates, Get Out Your Checkbooks

The Voice of Croatia, Deanovic has been off the air for some time. Now it seems to be serious about it. It is offering its 100-kilowatt transmitter and all of its associated equipment for sale. *Any pirate operators out there with really deep pockets?*

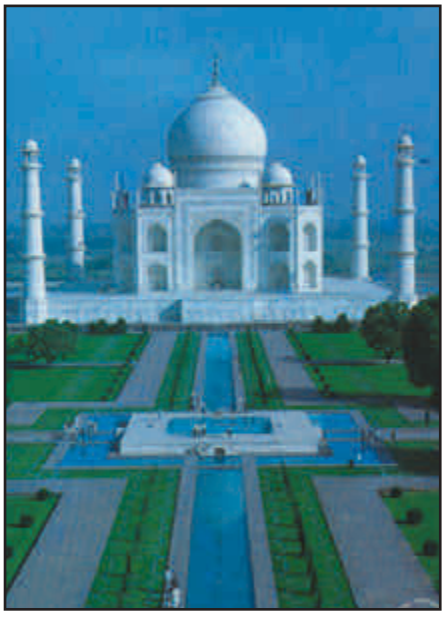
Good News: This Month's Shortwave-lets

• **Radio Aparecida** in Brazil's' like-named city, on 5030, 6135, 9630, and 11855 is installing new transmitters. I presume those will be of the same or higher power than those currently in use, which range in strength from 25 kilowatts down to one.

• I've seen reports to the effect that **Kol Israel** has returned to the air, using 15760 from 1400-1530 Sundays through Thursdays and closing five minutes earlier Friday and Saturday.

• Apparently shortwave from Greece isn't quite dead after all. A new public service broadcaster is in formation. It grew out of the ashes of the now-closed ERT (Voice of Greece). The new service, abbreviated as **NERIT**, initially focused on news reporting and will, presumably, add music and other programming as it develops.

• **Radio Sultanate of Oman** has added Arabic broadcasts on 9540 at 0400-1000.



All India Radio shows the Taj Mahal on this nice QSL received by John Miller in Georgia.

Rich D'Angelo got this nice card from RTE Radio, Ireland, broadcasting special coverage of the All Ireland Hurling Finals via Wooferton.

KVOH — The Voice of Hope confirmed one of its test broadcasts for Rich D'Angelo.

• **The Voice of Russia** says it ceased shortwave broadcasting on January first. There's some question as to whether that report is accurate. It may be that the cessation applies only to its broadcasts in Russian (a.k.a. *Golos Rossii*).

• **Radio Slovakia International** has returned to its former activity of airing half-hour transmissions. This challenging outlet is rarely heard in the early evenings.

SWLers: Now It's Your Turn

Remember, your shortwave broadcast station logs are always welcome. But please be sure to double or triple space between the items, list each logging according to home country and include your last name and state abbreviation after each.

And before you submit them, please proofread them. Several logs this month did not include the time and, thus, had to be omitted. Also needed are spare QSLs or good copies you don't need returned, station schedules, brochures, pennants, station photos, and anything else you think would be of interest.

And please include the transmitter site where appropriate. Also, how about sending a photo of you at your listening post? It's your turn to grace these pages. Feel free to send your photo via email.

Hint: Having your shack photo included would make you the envy of every reader of the *The Listening Post*.

SWL Listings:
For the latest SWL loggings, visit: <http://www.CQPlusListeningPost.blogspot.com>.

world band tuning tips

World News, Commentary, Music, Sports, And Drama At Your Fingertips

This listing is designed to help you hear more shortwave broadcasting stations. The list covers a variety of stations, including international broadcasters beaming programs to North America, others to different parts of the world, as well as local and regional shortwave stations. Many of the transmissions listed here are not in English. Your ability to receive these stations will depend on time of day, time of year, your geographic location, highly variable propagation conditions, and the receiving equipment used.

AA, FF, SS, GG, etc. are abbreviations for languages (Arabic, French, Spanish, German). Times given are in UTC, which is five hours ahead of EST, i.e. 0000 UTC equals 7 p.m. EST, 6 p.m. CST, 4 p.m. PST.

Public Safety Monitoring Gets Its Just Due @ Last Month's Consumer Electronics Show in 'Vegas

Exciting New Scanners Expand Uniden's HomePatrol Family

BY GORDON WEST, WPC6NOA/WB6NOA

Last month at the Consumer Electronics Show <http://www.cesweb.org> in Las Vegas, Uniden unveiled two new scanners — its great new BCD436HP and BCD536HP — with a companion app that will advance the consumer's HomePatrol-1 into a mobile and handheld scanner for the *serious* public-safety monitor, **Photo A**.

"Several years ago, *[Popular Communications']* CES coverage included our new [at the time] HomePatrol-1 table-top scanner," Paul Opitz said, **Photo B**. He is *the main man* in Uniden marketing. "Any scanner listener who knows their ZIP code could easily and quickly be listening to the local action!"

*(**WATCH and LISTEN:** To Paul Opitz detail the features of the BCD436HP and BCD536HP scanners in a full-length video at <http://bit.ly/18dAtFt>, **Photo C**. – WPC6NOA)*

***Photo A.** Uniden's new BCD536HP, left, and BCD436HP scanners take the HomePatrol concept to a whole new dimension. New features and integration opportunities are all over this radio! (Internet screen grab)*

You Asked for It

Opitz noted that people *really into* public-safety monitoring wanted a traditional-size scanner product for rack or mobile-unit mounting. Those same scanner users also wanted a true handheld HomePatrol-type scanner, plus the added capability of programming local systems into the radio, thus keeping the programming up-to-date as systems changed in response to narrow banding, re-banding, and system upgrades.

The scanner information database provided by Radio Reference.com <http://www.RadioReference.com> is a great avenue to take to find thousands of frequencies, but the die-hard scanner operator may know about local system "secret channels" and want to program them from the front panel.

Narrow banding and re-banding is in full swing, with APCO Project 25 Phase II taking analog trunking and digital channels to *a new high.*

New Uniden Handheld with 'TrunkTracker V' Technology

The new Uniden BCD436HP and BCD536HP scanners

***Photo B.** The wildly popular HomePatrol-1 tabletop scanner was the catalyst for Uniden's newly-designed and upgraded public-safety scanners. (Internet screen grab)*

**CQ Contributing Editor at Large*
2414 College Drive, Costa Mesa, CA 92626
e-mail: <wb6noa@cq-amateur-radio.com>

and their companion app were on display at CES.

"Our new BCD436HP is the first scanner to incorporate the HomePatrol-1's ease of use in a traditional handheld scanner," Opitz said. To get started with this new scanner, all it takes is entry of your local ZIP code, and the new handheld springs to life.

"The four gigabyte micro SD card holds the entire USA and Canadian database of radio systems, with plenty of room for recording hours of off-air audio," he said. The alert indicator can also flash in a user-set color and pattern when a specific channel becomes active.

Opitz calls this new digital technology reception "TrunkTracker V" to support P-25 Phase I and II, X2-TDMA — TDMA Motorola, EDACS, and LTR trunked radio systems, **Photo D**.

The new Uniden handheld includes a band-scope, trunked system analysis, RF power plot, and EDACS LTR location finder. Simply choose the type of channels you want to hear — police, fire, paramedics, and so on — enter your zip code, and the scanner will do the rest. You can also tie it into a GPS receiver in case you are driving cross-country and always want the scanner to stay tuned to local radio activity.

I especially like the "Close Call®" RF

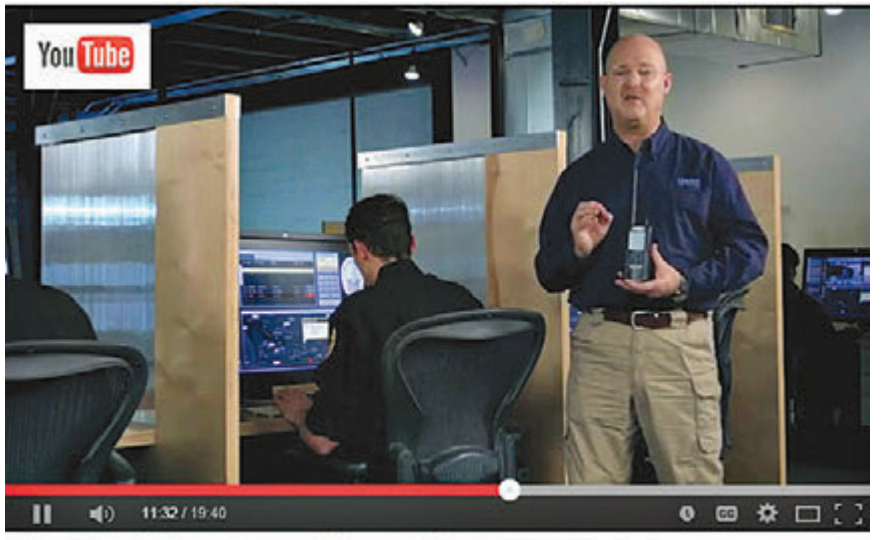

Photo C. *Uniden's Paul Opitz gives a 20-minute seminar on the new '436 and '536 in this online video at <http://bit.ly/18dAtFt>. Details about the new handheld scanner begin at 9:58. The new mobile unit is described in detail beginning at 14:53. (Internet screen grab)*

Photo D. *Uniden expects the retail price of the new BCD436HP to be $499. (Internet screen grab)*

bhi

Upgrade your station this Christmas..
..with a bhi
DSP Noise canceling product!

Our technology is designed to recognize speech and remove noise and interference!

New DESKTOP Base Station Speaker

HEAR IT Speaker
- "Quick Adjust" DSP control
- 8 DSP filter levels 9 to 35dB
- 2.7W Amplified DSP speaker
- 3.5mm mono headphone socket
- On/off audio bypass switch
- 12 to 24V DC (500mA)

Why not Have a festive noise free Christmas this year!

DSPKR

Superb 10W audio!

HEAR IT In-Line

- Amplified DSP In line module - Use with a speaker or phones
- 8 filter levels 9 to 35dB
- Separate input level and volume controls
- 3 Watts audio
- Supplied with 3.5mm audio plug lead, user manual & fused DC power lead

10 watt DSP extension speaker- 7 filter levels 9 to 24dB - Sleep mode - Filter store function - Volume control - Input overload LED - 3.5mm Mono headphone socket - 10 to 16VDC (2A) - Supplied with integral 3.5mm audio plug lead, user manual & fused DC power lead

The new bhi 10 watt DESKTOP speaker has a 4" bass driver and 1" tweeter - Digital rotary volume and filter level controls - Separate stereo line-in and speaker level inputs - Headphone socket - Audio & LED indication of filter function - Audio overload- Sleep mode - Noise reduction 9 to 35dB - 12V DC to 18V DC power (2.5A peak) - Weight 3.6lb, dims 8"(h) x 6"(d) x 6.3"(w) - Supplied with fused DC power lead, 3.5mm audio plug lead & user manual

Photo I. *A checklist of features in Uniden's newest handheld and mobile scanner shows the breadth of coverage these great units provide. (Internet screen grab)*

capture, that lets the scanner find nearby transmissions and its ability to program this mode without interrupting on-going scanner activity.

And for those of you in rural areas who still use two-tone paging, this handheld has you covered.

The handheld runs on three AA batteries and Opitz said it should play for up to eight hours on a set. I like the feel of this unit with its rubber sides and rubber bottom impact areas, in case it takes a trip down to the deck.

Mobile Scanner: Integration Opportunities Galore

Of course, the mobile scanner has all the same features as the portable scanner, and both units have *even more* features than the original HomePatrol-1. *(**WATCH and LISTEN:** To the Uniden BCD536HP mobile scanner on the air within minutes of being taken out of the box, **Photo E**, at <http://bit.ly/184C4AD>. – WPC6NOA.)*

Both scanners include Sentinel Software that will make the database and firmware updates simple. This software will allow you to create, edit, and manage your favorite channel list. It is USB-PC cable-ready to enhance managing all of the channels you have in memory. And, like the handheld, you can also program channels from the front panel, too.

Much More Information

Uniden expects the retail price of the handheld BCD436HP to be $499, and the mobile BCD536HP, $599. I talked Paul into giving us some nice sites to learn more about these two new scanners and the software app.

- BCD436HP and BCD536HP Manual, <http://bit.ly/18PN4lU>, **Photo F**
- The Uniden Home Patrol Discussion Page, <http://bit.ly/1bb1fSa>, **Photo G**
- Additional Uniden '436 and '536 information, <http://info.Uniden.com/NewScanners>, **Photo H**

Anxious Anticipation

No, at this writing I don't have one of these new scanners *yet.* I work the original HomePatrol-1 version regularly, so I can hardly wait for some hands-on time with the new mobile '536 and the new handheld '436 Uniden scanner receivers! **Photo I**.

BY RICHARD FISHER, KPC6PC/KI6SN

Getting Started in VHF-UHF Scanning Can Be Free and Easy as 'A, B, C, D!'

In this month's *Internet Radio* we're going to get serious about VHF-UHF scanner listening. There is a fascinating world of police, fire, aviation, governmental, radio amateur, weather, and so much more if you've got *a way to get there.*

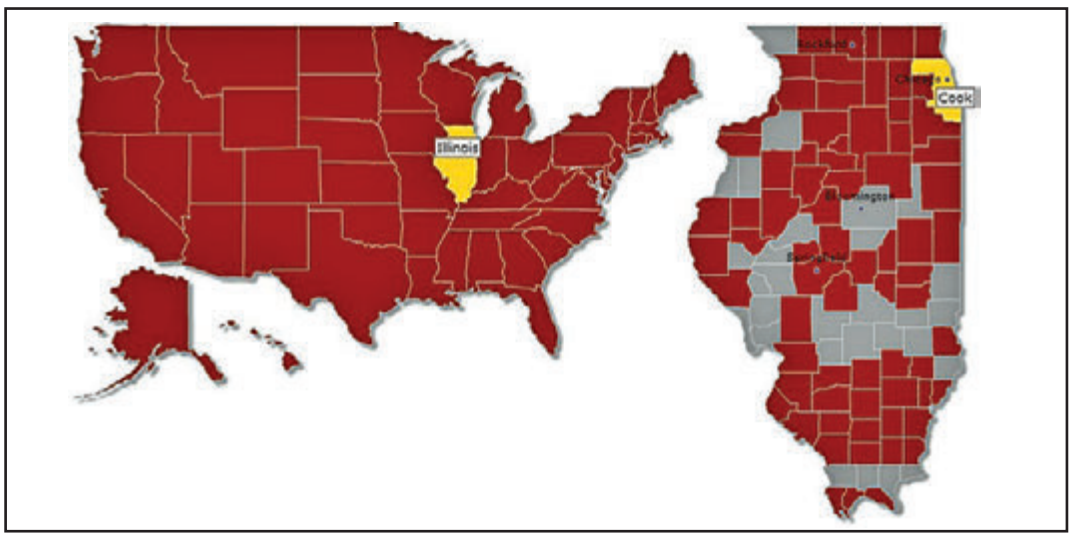
*1940 Wetherly Way, Riverside, CA 92506
e-mail: <CQPlusDigital@gmail.com>

Vagaries in wave propagation generally do not play a major role in "band conditions," so you'll find action in this part of the spectrum 24/7/365.

If you've never ventured into scanning, and would like to listen before making an investment in gear, there are portals on the Internet that will get you hooked up to scanners all over the United States.

Of course, there's no substitute for that radio

STEP A. *Link to the Broadcastify.com website at <http://www.broadcastify.com> and click on "Listen." We've circled it in yellow in this image to make it easy to find.*



STEP B. *Your next screen will look like the image on the left — the map of the United States. For our demonstration, we've chosen the Chicago Police Department as our target scanner. So we click on Illinois. That takes us to the image on the right: a map of Illinois segmented into counties. Chicago is in Cook County, so we click on it.*

STEP C. *Clicking on Cook County takes us to a list of all the scanners online from there. There are a lot! We scroll down to "Chicago Police Department" — which we've circled in red on the left. Click on the small triangle on the far left to activate the audio feed. Notice the number 409 on the right, also circled in red. This is a count of how many people are currently listening to this scanner feed. That's a pretty good indication that we're in for some urban police action.* →

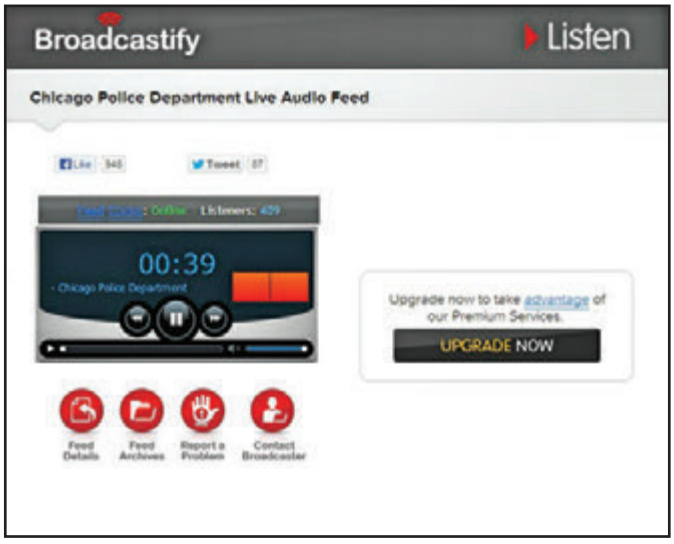
chattering away in the background, or hanging on your belt as you move around town — but "Internet Radio" offers you a no-cost way to test drive the spectrum before buying your gear.

To try things out, all you need is a computer or smartphone with audio and Internet access. Period. For our example, you'll get there by linking to Broadcastify.com <http://www.broadcastify.com>, a website that links users to 3,000+ VHF-UHF scanners across the country. Depending on your device's capability you may need to use another service such as TuneIn, Scanner Radio Deluxe, or other app. Just Google them and you're sure to find one that works.

With Broadcastify, simply follow our four-step process. There are no programs to download, accounts, or passwords to create, or antennas to put up.

STEP D. *Clicking on the triangle noted in STEP C brings you to this screen: Chicago Police Department Live Feed. There is a running clock ticking off the amount of time you are logged in. At the moment of this screen shot, we had been on the CPD site for 39 seconds. The orange blocks to the right of the clock bounce up and down with the modulation of the radio signals from the dispatchers and police officers. The bar below it to the right is the volume control. We have it cranked up to full volume and adjust the overall volume via our laptop.* →

Imagine: Listen to the fire department in your town, or the town *you used to live in.* Or, you've just heard on the news there is a major incident going down that's got national attention. The Boston Marathon terrorist bombing, for example. Sure, you can get a TV or radio reporter's perspective. But how about tuning in a Broadcastify.com police or emergency service scanner and hear the action first hand? *It's really as easy as A, B, C, D!*



New Members: *Monitoring Station* Program

Here are the newest station monitors granted a station identification sign, authorized a Certificate of Registration, and welcomed to the *Pop'Comm Monitoring Station* program.

KPC and DX Prefixes

They are listed by name, station identification sign, and monitoring station location.

Donald Osmond, Sr., **KPC4SKT**, Tega Cay, SC; Stephen Piwonski, **VKPC3AIR**, Melbourne, Victoria, Australia; Mark Prock, **KPC5KQQ**, Allen, TX; Joseph Havens, **KPC9ZDA**, Yoder, IN; James Andrews, **KPC8SSS**, Kettering, OH.

WPC Prefixes

Also: Darwin McDonald, **WPC8DMD**, Madison Heights, MI; John Green, **WPC3BV**, York, PA; James O'Neil, **WPC7JSO**, Newsmanstown, PA; Paul Rehkopf, **WPC-8PRR**, Montpelier, OH; Christopher Gearhart, **WPC1HWQ**, South Windsor, CT; Gary Dobbs, **WPC8GD**, Sarver, PA; Michael Fontaine, **WPC4BBS**, Wesley Chapel, FL; Jeffrey Marker, **WPCØFYV**, Raytown, MO; Christopher Jerry, **WPC4CJ**, Jensen Beach, FL; William Abshear, **WPC1QDR**, Waynesville, OH; William Harrison, **WPC4SC**, Elgin, SC; John Bishop, **WPC4LPF**, Melrose, FL.

For complete information on the *Pop'Comm Monitoring Station* Program and to join, visit *Pop'Comm Monitors On the Web: <http://popcommmonitors.blogspot.com/>.*

Commander Bunny, the Pirate Who Would Be President

With No Apologies, He Takes On the Government and the Human Race

This month we have an interview with long-time shortwave radio pirate Commander Bunny of WBNY fame. Not only will we look at his long pirate radio history, but we get a very interesting glimpse of the "inner Bunny." *(**LISTEN:** To a 6+ minute audio clip from Commander Bunny in a YouTube posting from February 2011 at <http://bit.ly/18jvo41>, **Photo A**. – WPC6JXK)*

***[Handler]** First, the obvious question: What motivated you to become a shortwave pirate broadcaster?*

[Commander Bunny] I have always had a shortwave around, listening to my dad's in the 1950s. During the '60s I heard of *pirate* broadcasters via *Popular Electronics* magazine. That set my imagination soaring and I searched often, and once in a while would find an errant ham playing music. But I felt there was a niche I could fill.

I picked up a Johnson Viking Ranger in 1965 from the wife of a *silent key* [deceased amateur radio operator] neighbor, **Photo B**, and decided after a year of being cautious and waiting that I would have some fun.

I had spent many hours in that neighbor's basement, being *Elmered* [mentored] by him on all things electronic. Plus my dad had been a telegrapher on ships in the 1920s and '30s. So I grew up around it.

e-mail: <Stevenhandler-popcomm@yahoo.com>

***Photo A.** A YouTube posting from February 2011 captures about six-and-a-half minutes of a Commander Bunny broadcast on shortwave. (**LISTEN:** At <http://bit.ly/18jvo41>.) (Internet screen grab)*

Fun has always been what I wanted to have and still to this day remains my motivation. That's fun *for me,* and hopefully fun for people listening. If there is any bigger rush than firing up a transmitter and throwing a signal into the ether, not knowing where it will go, or if you might get caught doing it, then I don't want to know about it.

Then you add to that a program that you created and there isn't a drug on the face of the planet that can give you a bigger adrenaline rush.

*(**NOTE: Photographs C** through **K** were provided to Pirate Radio courtesy of Commander Bunny. – WPC9JXK)*

***[Handler]** I understand that another pirate operator originally used the callsign of WBNY. When did you begin operating WBNY and how were you affiliated with the original WBNY pirate station operator?*

[Commander Bunny] Your understanding is wrong — just another nasty rumor floated by the shadowy figures who have nothing better to do with their time on supposed pirate blogs than throw out lies, gossip, and rumors.

This *rumor* didn't start up until the mid-2000s when I was on the air just about every weekend. This was also about the time that [Internet] *chatrooms* came along and the rumors about every pirate operator or suspected pirate operator became the norm.

If I went around denying or trying to correct all the rumors and gossip about me, I wouldn't have time to broadcast. This is the one part of [pirate radio] that detracts from the fun. Sadly this comes with pirate radio fame. The more famous and well known you become, the bigger target [you are] for the jealousy and snipes.

I've had one especially nasty stalker who has blamed me for everything from FCC busts to deleting one of his posts on a pirate website. *Trust me about this:* Only one person knows who I really am, and that's my drop operator [the person who receives mail and forwards it to the pirate broadcaster].

There are lots of rumors about who they *think* I am; who they *think* I sound like and some claim they know — but none of these [guesses have been] even close.

The first rule of pirate radio is *trust no one*. And I haven't.

WBNY has been on the air in one form or another every Easter since 1966. Were I any of the people the *know-it-alls* claim, I'd have been shut down long ago.

While the Internet has brought reception reports almost immediately, it has also given a big voice to the gossips and rumor mongers. Believe nothing you read on blogs and websites. These are just

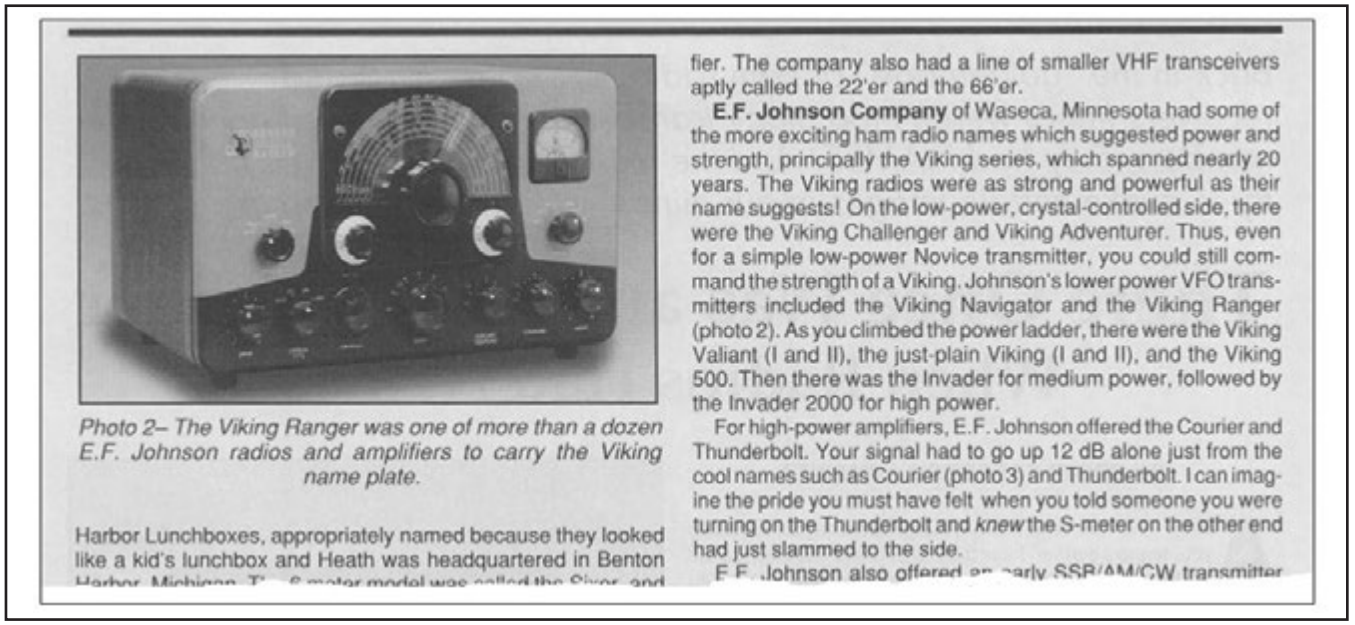

Photo 2– The Viking Ranger was one of more than a dozen E.F. Johnson radios and amplifiers to carry the Viking name plate.

Harbor Lunchboxes, appropriately named because they looked like a kid's lunchbox and Heath was headquartered in Benton

fier. The company also had a line of smaller VHF transceivers aptly called the 22'er and the 66'er.

E.F. Johnson Company of Waseca, Minnesota had some of the more exciting ham radio names which suggested power and strength, principally the Viking series, which spanned nearly 20 years. The Viking radios were as strong and powerful as their name suggests! On the low-power, crystal-controlled side, there were the Viking Challenger and Viking Adventurer. Thus, even for a simple low-power Novice transmitter, you could still command the strength of a Viking. Johnson's lower power VFO transmitters included the Viking Navigator and the Viking Ranger (photo 2). As you climbed the power ladder, there were the Viking Valiant (I and II), the just-plain Viking (I and II), and the Viking 500. Then there was the Invader for medium power, followed by the Invader 2000 for high power.

For high-power amplifiers, E.F. Johnson offered the Courier and Thunderbolt. Your signal had to go up 12 dB alone just from the cool names such as Courier (photo 3) and Thunderbolt. I can imagine the pride you must have felt when you told someone you were turning on the Thunderbolt and *knew* the S-meter on the other end had just slammed to the side.

E.F. Johnson also offered an early SSB/AM/CW transmitter

Photo B. *A Johnson-Viking Ranger transmitter, given to him by the widow of an amateur radio operator neighbor, opened the transmitting world of pirate radio to Commander Bunny. (With permission, courtesy of CQ magazine)*

Photo C. *Here's an example of a WBNY Relay Service QSL. (Unless otherwise noted, images courtesy of WBNY and Commander Bunny)*

people who want attention because they can't broadcast or if they do anything worth listening to.

[Handler] *When you began operating WBNY what were you trying to accomplish, and along the way have your goals changed?*

[Commander Bunny] The first goal was not to get caught. Remember this was the '60s and the FCC agents of that day were the hard-core, no-nonsense guys you didn't want banging on your door at 2 a.m.

Seriously, I just wanted to have some fun, poke fun at the government, poke fun at the way human beings — [all of whom the Commander considers] *monkey-boys, ape-humans* — act and treat each other.

For the first 10 years of doing WBNY, at least the Easter broadcasts, I had no way of knowing if anyone even heard, except after I'd go off the air, someone would answer [on the airwaves] and say *that was funny* or *thank you!* It was enough to keep me trying.

Remember back in the day, you'd have to find a shortwave broadcast station that wasn't on the air and use that frequency before or after they came on the air.

Although 6 to 7 MHz has always been popular, I've gone to 4, 9, 13, and 20 MHz and even below and above the Citizens Band.

It was during the '70s that newsletters started popping up with some serious pirate listeners posting logs. But these newsletters were only published every other month, or so. But it at least gave you an idea that more than a couple people were hearing you.

The '80s brought not only monthly newsletters — *Free Air* and *The Association of Clandestine Radio Enthusiasts* (ACE) — but dial-up BBSs.

The '90s saw the Internet start to make some inroads — *Free Radio Network* — and establish some real two-way communications between listeners and operators.

The 2000s started off pretty good, but by 2010 it had attracted a lot of negative people who wanted attention at any cost. Pirate radio is about creating programs and broadcasting them, not blogging and posting.

It does appear that a lot of the negative folks have found other shiny objects to keep them occupied now ... but the mess they left will take a long time to clean up. Your question about *the original* is but one of the false rumors floating about.

[Handler] *You created the character of Commander Bunny, a rabbit that heads the "Rodent Revolution." The goal of this revolution apparently is having the rodents seize control of the planet from the human population — which you often refer to as "ape-humans," "monkey boys," and similar terms. What was your inspiration for the character of Commander Bunny?*

[Commander Bunny] I'm not sure I had an inspiration. Darwin? Making fun of the evolution deniers who can't see that all humans act like monkeys, most of the time?

Can anyone deny that things wouldn't be better if the rabbits ran things? I took a lot of what was in *Planet of the Apes* in the late '60s and incorporated that story line into the *Commander Bunny* persona.

Instead of monkeys running things it would be rabbits (rodents) and well, yeah, humans would be the slaves. Face it, humans — as we know them today — have only been

Photo D. *Commander Bunny is a candidate for U.S. President — at every opportunity.*

around for maybe 1 million years. Our planet is 4.5 billion years old. Who was running the show before humans? Who will run it when humans are gone? And there is no question humans will be gone at some point.

Has there ever been a more arrogant creature on Earth than people? Next logical *(?)* step would be for the rabbits — *rodents* — to take over.

[Handler] *At some point you came up with the idea of your character, Commander Bunny, running for U.S. President. When did you begin this story line and what was your inspiration for this idea?*

[Commander Bunny] It was 2004 and there were 12 — *count 'em* — 12 candidates on the election ballot. If John Kerry and Ralph Nader could run for President why not *Commander Bunny*? I had bumper stickers and QSLs made up for the event and the feedback was awesome. I don't know how many votes I got. I'm pretty sure the machines were rigged. But the shortwave community thought it was great! I got a lot of fun, positive feedback. And I still do to this day.

[Handler] *What were you trying to accomplish with the Commander Bunny for President story line and have you accomplished those goals?*

[Commander Bunny] My goal was to establish that *anyone* can run for President. I have run for President ever since. Hey, going in the direction we're going, my candidacy isn't looking so bad now, is it?

It was also a reason to have another type of QSL printed up. I really believe that a fun, different QSL makes the pirate radio experience worthwhile.

I know the newer generation of pirates do e-QSLs, but there isn't anything better than sending off to some strange post office box with your report, then waiting for a QSL to show up — a [card] you can hold in your hand, show your friends, and hang on your listening shack's wall. I fear the *real-QSL* event is being lost to technology.

[Handler] *Your broadcasts tend to have very high production values. Once you have envisioned the concept or theme of a show, please describe the artistic and production process it takes to move from an idea or concept to a final broadcast.*

[Commander Bunny] Sometimes the inspiration comes quickly, the elements of the show fall into place and I can put together a 45-60 minute show in two to four days [consisting] of six-hour sessions at the mixer and computer.

It may sound flawless and effortless, but *trust me*: It is a labor of love. I have a Yamaha 8-in, 4-out stereo mixer and lots of years' worth of parody songs and silly commercials. I work out the basic idea of the show in my head. Then, as I'm putting it together, all the pieces seem to fall into place. *Monkey* songs just seem to show up from listeners who send them or I'll find it at an old record store or at a yard sale.

[Handler] *Once you have your script written, about how long does it take for you to create one of your programs?*

[Commander Bunny] I usually get the idea in my head, think about what I'm going to do, write a basic script, then sit down at the mixer and keyboard. I'll get the thoughts about the program written down — script and technical notes — and the rest of it usually ***(NOTE:*** *usually)* comes after that. Sometimes it's like pulling teeth, but that's the exception, not the rule.

[Handler] *Are your program recordings done in a single take, or do you use multiple takes, and if so, about how many on average for a show?*

[Commander Bunny] The voice part of it is done in a single take. I want a flow to the program. Doing edits interrupts [that flow]. Remember, I've

Photo E. *This WBNY Relay Service QSL celebrates the recent FCC shutdown.*

Photo F. *A commemorative Commander Bunny for President coffee mug hails the Rodent Revolution and declares "America Needs a Hare Transplant."*

Photo G. *The WBNY Relay Service relays "the best of pirate for MWNT (monkeys with no transmitters)."*

Photo J. *WCS, The Collective Soul Station, is on the air thanks to Commander Bunny and WBNY.*

already written the script in my head, then written it down so the script is more like notes. It's the editing that takes an enormous amount of time and sweat.

[Handler] *Your broadcasts have made use of satire, one of the oldest and most sophisticated forms of humor. Do you write all of your material or do you have someone who assists you?*

[Commander Bunny] Nope, there's no one but me to blame. I read newspapers, watch the news, follow politics, see posts on the FRN (Free Radio Network) and see how silly people act. Satire is simply observation of the obvious. I suppose it's a point-of-view issue. You see the United States Congress in session (when it isn't on vacation, in recesses, or during a shutdown) and I see monkeys acting (OK, so it isn't an "act") like idiots. Do you watch *CSPAN* or John Stewart on *The Daily Show?* **Photos L** and **M**.

[Handler] *In the use of satire, how do you balance your right to free speech against airing material that some in your audience may find offensive?*

[Commander Bunny] The only thing that any of my listeners have found offensive is my use of the *monkey-boy* and *ape-human* phrases. I am still amazed by how much those terms made people angry.

So someone who calls himself *Commander Bunny* calls you a *monkey-boy* and you're going to take it seriously? *Really?* That's too funny!

Anyone offended by language should probably find a nice PBS station, not pirate shortwave radio. There's not a lot of vulgarity in my shows, but you probably won't be hearing any of the WBNY programs on the local *Baptist Hour.*

[Handler] *I understand that beside WBNY and WBNY Relay Service, you have operated many other pirate radio stations with varying formats and persona. Commander Bunny's revolution is now in its second decade. Do you have a desire to try something different and if so, what?*

[Commander Bunny] *Commander Bunny* in his current state is in his *third* decade. WBNY is in its *sixth* decade. The majority of my broadcasts are relays for other pirates now, and I'll continue to do that. I never know what will happen until the urge strikes me.

[Handler] *Throughout your pirate broadcasting career, is there a single broadcast that stands out from the rest as your "best broadcast" and if so, please tell us about that program.*

[Commander Bunny] That's kind of like asking a parent — with their kids standing there: *Which child do love the most?* They have all been fun. Fun to think up, fun to write, fun to produce, and fun to air.

It has been fun to send QSLs and fun to hear the reaction of the QSL packages. I usually send a super QSL package to about the fourth confirmation, but if one hits me funny, I'll send them the whole tote-bag (spoof on PBS), coffee mug,

Photo K. *This QSL is for WHOF — Hall of Fame Radio — which broadcast through the facilities of the WBNY Relay Service.*

pens, magnets, *yadayadayada* as my appreciation of their getting the joke!

OK just thought of my favorite show: It was the *Good Monkey* show. I had asked both on the air and through the FRN (Free Radio Network) for people to send me audio with them saying, *I'm a Good Monkey.* I got more than I ever dreamed of. It took me weeks of daily editing to get them all in, but I did.

I counted 74 different clips of people saying *I'm a Good Monkey* on that show. It showed not only how many people listen but are willing to take the time to cut an audio piece for the show.

My favorite Easter show (that was what got me started with WBNY) is the Easter 2007 show where I incorporated a South Park program about why Easter eggs are painted and why the Pope has a big hat (to hide his bunny ears).

[Handler] *As a pirate shortwave radio operator, have you accomplished all of your goals and if not, what's left?*

[Commander Bunny] Well, since all I ever wanted to do was have fun, I think I have. Each station I have created over the years was for a specific purpose that, at the time, met the goal I wanted.

The one goal that I've accomplished and enjoyed is being a Relay for pirates who don't have transmitters. I've relayed hundreds of pirates who either didn't have a transmitter or just wanted to throw the FCC off by having them pop up from a different part of the country.

I've made many friendships because of the Relay function. A lot of very talented people are out there who have great, creative ideas but have no way of getting them on the air. It has been a ball to provide them with a way to get their programs broadcast. But the underlying goal of having fun has been met and continues to this day.

[Handler] *The licensed shortwave broadcasting community is contracting worldwide. Having been both a participator in, as well as an observer of shortwave radio broadcasting, what impact will the demise of many licensed shortwave broadcasters have on pirate radio broadcasting in North America?*

[Commander Bunny] It's not just shortwave. It's the entire broadcasting world. Have you listened to AM and FM radio lately? Broadcast listenership across the board is declining. Shortwave is a niche group of hardcore, "I love radio*"* kind of person. And the *pirate shortwave radio* kind of person is an even smaller niche, but in my opinion it will continue in spite of what commercial radio does.

The fact that they have a shortwave and listen to it speaks volumes to their commitment to a very unusual hobby. The demise of commercial shortwave should open up some frequencies for pirates.

The typical commercial shortwave broadcaster splatters for 50kHz +/-, so pirate listeners aren't going to miss them in the least. It is funny how the FCC will chase 50-watts-or-less pirates but can't seem to find the time to go after the 100-kilowatt "*splatter-the-entire-band"* commercial stations.

As long as they make shortwave receivers, there will be shortwave listeners and then a niche of folks who find pirate shortwave even more appealing than listening to commercial preachers begging for money or hams arguing over who *had the frequency first.*

During the era around 2005, there were some people who complained about the low-power pirates and *who wants to listen to a low-power pirate?* These are the Generation X, *gimme everything right now* group, that has since moved on to something less challenging than pirate radio.

The romance of hearing a low-power pirate broadcaster is lost on that generation. It wants FM high-powered, *don't make me work for stations.*

Pirate radio is not for them. But to the point, the demise of the big 100-kilowatt shortwave stations will make low-power pirate reception more attainable.

Photo L. *Commander Bunny tunes into John Stewart and The Daily Show for perspective on the content of WBNY broadcasts. (Internet screen grab <http://www.thedailyshow.com>)*

[Handler] *What role in pirate radio broadcasting do you envision for yourself in the future?*

[Commander Bunny] I'd say: staying at least one step ahead of the FCC!

I don't see me doing anything different in the future than what I've done in the past. It has worked for six decades. *Why stop now?*

I don't try to lead anyone or make anyone believe anything they otherwise wouldn't believe. My role isn't to be a leader in pirate broadcasting. My role is to practice my craft and have fun doing it.

WBNY, Commander Bunny, Radio Free Speech, and all the other stations were done as entertainment and for

Photo M. *The machinations of Congress, as covered by CSPAN, is a source of inspiration for Commander Bunny.*
(Internet screen grab <http://www.c-span.com>)

fun. Whatever role that has in pirate radio, then that's what I'll be doing. *Nothing more, nothing less.*

The people trying to bend public opinion or attempting to mold a movement or tell people they know who a pirate is, or have some tidbit about an operator — they have another agenda. It's an agenda I don't share.

These are the same people who sit next to you in a magic show and after the trick is performed have to tell you *how it's done.* I don't want to know how it's done, I want to be tricked into thinking it's something magical.

Pirate radio, at its very essence, is magic. It's some crazy guy (or gal) pretending to be some made-up personality, convincing you of it, putting that pretense on a shortwave transmitter, making it travel through the air and into your radio. *If that isn't magic, then nothing is.*

All of these people who have Internet blogs who pass along the latest rumor, or spread gossip, are in it for themselves *and no one else.*

My respect goes out to all the operators who create shows, then broadcast them for the entertainment of all. It's a shame someone would attach themselves to something that is so much fun, and have nothing but negative comments about who does it and how they do it.

Why would you set up a so-called pirate blog to *out* pirates' identities? How does that make you a part of pirate radio?

Pirate radio has been a wonderful outlet for my views and comments on society and government. It was a natural outlet for my technical abilities.

I am not a ham operator and never have been. I'm not going to agree to let the government come into my home, anytime they want, to *inspect* anything. But I know code, transmitters, and antennas.

Regulating radio waves is like telling people how much sunlight they can use. If you aren't interfering with anyone and operating a low-power HF station on a frequency that is not in use, I don't see what the problem is.

Like the guy on a deserted stretch of Interstate: No is one around. See how fast your car will go. *Who does that hurt?* This *Mama-government* mentality has led to what?

- Well, the latest government shutdown
- AM-FM and shortwave broadcasting collapsing

[It's just that] the average person can't tell the difference between the shutdown and when [the government isn't] working.

I don't *hate* government. I just think there is *way too much* of it. Tea Partiers are left-wing radicals (yes, I said *left wing*), in my view.

In Appreciation

I wish to thank Commander Bunny for taking the time and effort needed for this interview. – WPC9JXK.

'Commander Bunny' Pirate Stations

Alphabetically, here is partial list of pirate radio stations operated or relayed by Commander Bunny.

- Al Fansome Eulogy Radio – Ode to Kevin Miller
- All Average Music Radio
- Cathedral of Chris Radio
- Cell Phone Radio
- Comet Project Numbers Station Spoof
  (LISTEN: *<http://bit.ly/hpaVyv>)*
- Dobson Monkey Radio
- Elvis Annual Birthday Radio
- Family Radio spoof station
- Hitch Hikers Guide to the Galaxy Radio
- KDRM – K drum radio (all drums all the time)
- KRAP Radio – all crap all the time
- Marine Corps Birthday Radio
- Mouth of Mohammed
- My New Underpants
- Radio 9
- Radio Free Speech
- Radio Fudd
- Radio Slack – Church of the Sub-Genius
- Stairway to Heaven Radio
- VOM Voice of Mel (Blanc)
- VOTE – Voice of the Extremist
- We Monkey Radio
- WBNY – Radio Bunny
- WBNY – Relay Service
- WHOF – Hall of Fame Radio
- WJAY – Jay Smilkstein Radio
- WJVR – John Valby Radio
- WMDR – World Monkey Domination Radio
- WRAY – Link Wray tribute station
- WPDR – President's Day Radio
- WRRR – World Rabbit Rapture Radio
- WTKY – Turkey Radio
- WTPR – PT-1 & PT-2 Tire Pressure Radio
- WWWW – All W's all the time
- XENU – Over lord of the Universe (Scientology spoof)

trail-friendly radio

BY RICHARD FISHER, KI6SN

Measuring Your Location's Antenna Possibilities Without Leaving Your Computer

Space: The final frontier. OK, we're not aboard the *Starship Enterprise.* And for radio amateurs, the frontier of *space* is far from final. Indeed it's ongoing, especially where antennas are concerned. So let's strike that line of thinking.

Many hams who work the high-frequency (HF) bands — 1.8 through 28 MHz — find themselves refereeing a wrestling match with *Lot Space vs. Antenna Length* on the top of the card.

It can be hard to calculate the HLD (height, length, direction) possibilities when you're standing in the middle of your backyard craning to see the tops of a couple of trees with the Sun in your eyes.

"If my antenna goes from *there* to *there* and makes a turn *there,* can I fit an 80-meter dipole on this suburban lot?" is the question. "And what will my spouse think?"

Everyone: To the Web!

We'll leave the last question for another installment of *Trail-Friendly Radio.* As for the antenna and space calculation, though, there's a really cool site on the Internet that can take out almost all the guesswork. It's *FindLotSize.com* and can be used to measure point-to-point distances on virtually any piece of land in the world.

By the way, this program is perfectly suited for the shortwave-antenna builder, as well. *So, SWLer's read on!*

*1940 Wetherly Way, Riverside, CA 92506
e-mail: <CQPlusDigital@gmail.com>

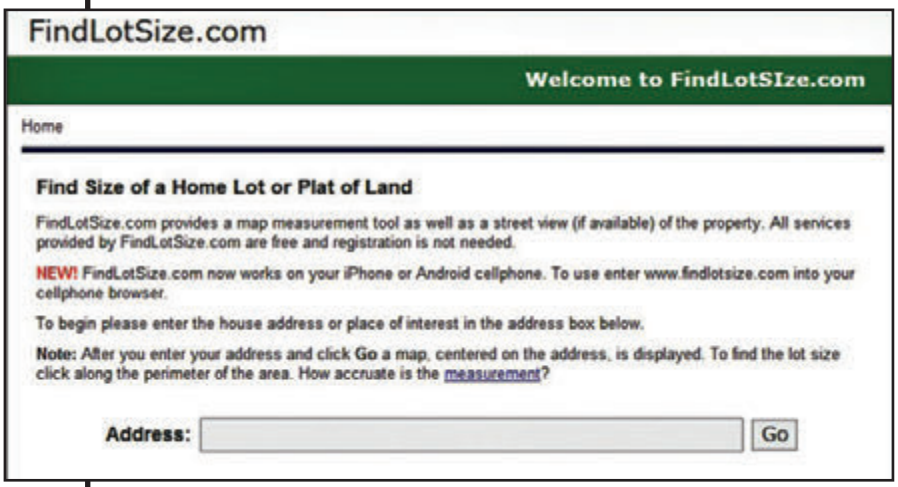

Photo A. *The welcome page at FindLotSize.com features an address box that will "find" the location of the antenna you're thinking about putting up. (Internet screen grab <http://www.FindLotSize.com>)*

Link to <http://www.findlotsize.com> and let the adventure begin.

Upon landing there you'll be greeted with a welcome page that invites you to punch in an address. In your case, the one at which you want to string your antenna, **Photo A**.

Trail-Friendly Calculations

For demonstration, Martha McLean Anza Narrows Park, at 5759 Jurupa Avenue in Riverside, California was typed in. Hit "GO" and you're linked to an aerial view.

This beautiful park in Southern California is a great place for trail-friendly radio operation. The sprawling open space is dotted by towering trees — many providing shade over picnic tables.

This location had been used here several times for portable operation on the higher HF bands — 20 and 10 meters. But what would be the possibilities for working, say, 80 meters from the park now that the summer static has given way to winter quiet?

Knowing the landscape, two giant trees on a gently sloping hill might be perfectly positioned for a dipole cut for 3.6 MHz. Would a half-wave dipole antenna fit? And where would its feed point fall?

By pointing and clicking on the top of each tree, FindLotSize.com — toggled for "Distance" — instantly gave the information needed, **Photo B**. The distance between the map pins is 177 feet — more than enough for a 130-foot-long, 80-meter, half-wave dipole cut for 3.6 MHz. In fact, it could hang in open space with the dipole's end ropes stretching about 24 feet from each treetop. The coax feed line would drop midway — about 88 feet from the base of each tree. All of this calculated from two simple clicks in the FindLotSize.com program. *How great is that?*

For City Slickers

But say we are on a city lot that could in no way accommodate a straight, horizontal low-band antenna. *Time to get creative.*

Let's imagine we're at the address of one of the childhood homes of radio pioneer Edwin Howard Armstong — on the Upper West Side of New York City. The SSB leg of the *CQ World-Wide 160-Meter Contest* is this month — February 21-23 — and we want in on it. But from New York City? *How?*

Turning again to FindLotSize.com, we punched in the legendary EHA's address and consider the possibilities.

Photo B. *By clicking on the treetops shown in this aerial map at Anza Narrows Park in Southern California, it's easy to calculate the distance between them — 177 feet — which is displayed at the lower left of the FindLotSize.com page, provided the "Distance" button above it is clicked. (Internet screen grab)*

Photo C. *Got an antenna configuration that isn't in a straight line? FindLotSize.com handles such distance calculations easily. Put in as many map-pin turning points as you'd like. (See text.) (Internet screen grab)*

Yes, we have trees.

How long is a half-wave dipole for Top Band? Using [468/Freq. in MHz] we see it's 260 feet, or 130 feet per side [468/1.8 = 260; 260/2 = 130].

Hummmm. Starting from the tree in the backyard, **Photo C**, we plot a line to one in the front. Then turn left to a tree across the driveway entry. FindLotSize.com calculates 309 feet — circled in red in our graphic for reference. *Great!*

And imagine the center-fed coax would have had a rather short run to the top floor EHA's bedroom window facing the street. *Perfect!* Who says you can't work Top Band from the inner city?

*(**CAVEAT:** Remember, this is the "site" of the Armstrong house. Obviously, a lot has changed since he lived there as a child. We're only "imagining" the trees were there when he was. And who knows what the house and surrounding area looked like. – KI6SN)*

Add as many map pins as you'd like. The program is perfect for measuring the possibilities of dipoles, long wires, loops, rhombics — in the country or the city. Measure the circumference of your suburban lot. Let your imagination run wild.

But How Do I Calculate Tree Height?

Length is one challenge. Height, another.

Here are four easy steps to calculate the height of any distant object. In our case, a palm tree supporting a sloping G5RV at KI6SN certainly qualifies, **Photo D**.

- Find a stick that is equal in length to the distance from your cheekbone to your fingertips when your arm is fully extended in front of your face. Breaking a branch to proper length will work just fine. *This isn't rocket science.*
- Hold the stick vertical by the tips of your thumb and index finger and put it in front of you with your arm fully extended and parallel to the ground.
- Walk toward or away from the tree until the top of the stick is visually lined up with the top of the tree and the bottom of the stick is lined up with the bottom of the tree. Visually, think of the stick *eclipsing* the tree — like the Moon covers the Sun in a solar eclipse.
- *Viola.* The distance from where you are standing to the base of the tree is equal to the height of the tree. Use a measuring tape if there's one handy. If not, measure the approximate distance between your steps as you walk naturally. Count the number of steps you take to the base of the tree and multiply it by the number of feet and inches each of your steps cover.

Photo D. *A stick cut to the distance between your cheekbone and fingertips when your arm is extended is all you'll need to calculate the height of a tree you're eyeing for a new antenna. It's part of a simple four-step calculation that* works every time. *(See text.) (Courtesy of KI6SN)*

That's all there is to it. ***(WHAT'S UP?*** *The G5RV is 35 feet high in the palm tree at KI6SN. The stick used as the "eclipser" is piece of plastic cord channel 2-feet, 5 1/2-inches long — the distance between my cheekbone and extended fingertips. – KI6SN.)*

Next Steps ...

So, there you have it. If the weather's too crummy right now to do any meaningful outdoor antenna work, link to FindLotSize.com to begin preparing for spring and summer. It's never too early to determine if antenna dreams for your yard or 2014 ARRL Field Day site are going to "measure up!"

BY BRUCE A. CONTI, WPC1CAT

Listening Waters: A Prince Edward Island DXpedition

As in Real Estate, for AM BCB DXers It's 'Location, Location, Location'

Finding a DX location on Prince Edward Island during the November 2013 off-season was a challenge. Most rental properties, especially beachfront vacation cottages of primary interest for saltwater enhanced DX, were closed for the season by the end of October. Fortunately, thanks to the Internet and Google Earth, chances of finding a good spot improved considerably without ever leaving home.

After a successful 2012 DXpedition in Howe Bay on the southeast shore of Prince Edward Island, it was decided to do it again. This prime location provided saltwater paths to Europe, the Middle East, and Africa, along with the Caribbean and South America. Unfortunately the Howe Bay cottage was not available this time. So the search for a new site was underway, beginning with identification of desirable towns on the southeast shore of the island, followed by a Web search for cottage rentals in those towns. Then it was just a matter of checking the listings for properties that were open year 'round.

e-mail: c/o <CQPlusDigital@gmail.com>

PEI DXers. *Members of the 2013 Prince Edward Island AM BCB Listening DXpedition team, from left, were Bruce Conti, Walt Salmaniw, Niel Wolfish, and Brent Taylor — ready for action. (PEI images courtesy of WPC1CAT)*

Once the search was narrowed to just a few still available in November, the sites were located on Google Earth for evaluation. Locations in a compact residential neighborhood, not actually on the beach, or in some cases not even close to being as advertised, were eliminated by Google Earth aerial visits.

What a great tool — something anyone can use to check out locations before ever setting foot on a site or contacting the landlord.

Culling the Choices

The search was narrowed to five potential properties. Now it was time for DXpedition leader and island resident Brent Taylor, VY2HF, to scout the sites with a portable radio to check for noise problems before making any final decisions.

Two properties were selected, but the first contact with a proprietor was negative, as it was not available off-season. Our next best site was on 17 acres of beach front; the Glistening Waters Victorian Farmhouse in Murray Harbour North.

Seventeen acres on the water was a rare find, and if available in November would be even rarer. *Success!* Although the owner had never before remained open so late in the season, she agreed to accommodate us for a week in November. In fact, she was intrigued by our upcoming adventure. *The DXpedition was on.*

It didn't take long for the word to get out about another Prince Edward Island Listening DXpedition either. The farmhouse — from here on dubbed *Listening Waters* — could accommodate four DXers comfortably: The core DXpedition team of Brent Taylor from Stratford, Prince Edward Island; Niel Wolfish, from Toronto; and me from New Hampshire, plus one more. In only a matter of days, Walt Salmaniw, of Victoria, British Columbia, secured the fourth seat. For Walt, an accomplished West Coast North America DXer, this would be his first East Coast DXpedition.

Pre-DXpedition Planning

"Planning ahead is essential anytime multiple operators are involved and when factors of significant travel distance, lodging expense, etc. are in play," recommended medium-wave broadcast band DXer Mark Connelly, WA1ION, as he took an interest in our pre-DXpedition planning.

DXpedition Ground Zero. *Here is the Listening Waters Victorian Farmhouse in Murray Harbour North, on the southeast shore of Prince Edward Island.*

"It's not quite the same as a solo — or maybe a two-person — local deal when at 2 p.m. you say, *Maybe I'll shoot over to the beach for a quick session at sunset,* and that beach is less than an hour's drive from the house," he said.

"If you forget some power cord or a BNC/UHF adapter and then — as you sit at the site in a non-functional DX state — you realize that you will have to bump things to another night, the most you've wasted is maybe a couple of hours driving around.

"If, on the other hand, you've taken days off from work, invested $1,000 or more just to get to (and) from the site, and, even worse, several of your friends who spent just as much to get there are depending on you, then you've really boned up if you left something important at home. *So plan ahead!"*

Strategies via Email: Things to Bring

The packing list was most critical for two DXpedition team members who would be flying in. Airport security, baggage fees, and the potential for lost luggage place limitations on what can be carried without risk. Some of the planning discussions via email exchanges went like this:

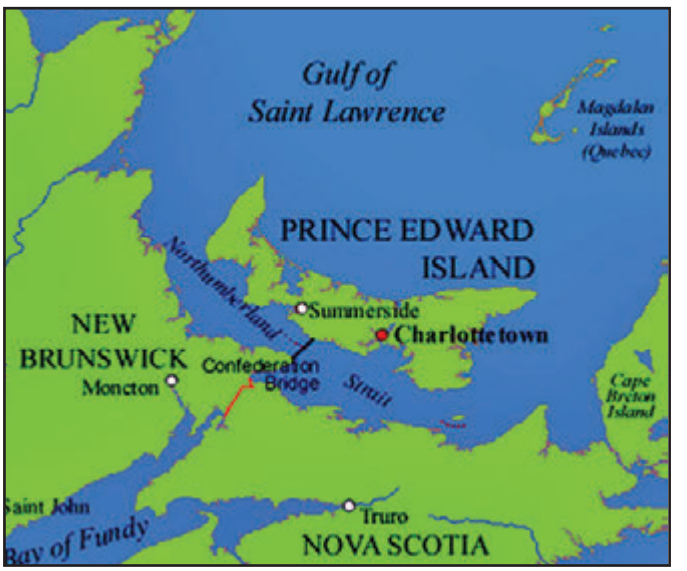
"Counting down the days!" exclaimed Walt. "A question for the group. Perhaps I've forgotten if you've already mentioned what to bring as far as DX equipment. What do you suggest as far as connectors, splitters, antenna switches, coax, etc.? I wouldn't want to come out having forgotten something crucial!"

"I guess, from your perspective, you would want to have at least BNC cables to attach to each splitter and then a switch to select between/among antennas," replied Brent. "I have a Wellbrook active 4-way splitter and I believe Niel does also. I think last year we powered them from one of my 12-V storage batteries so that there is one less switching power supply on the go.

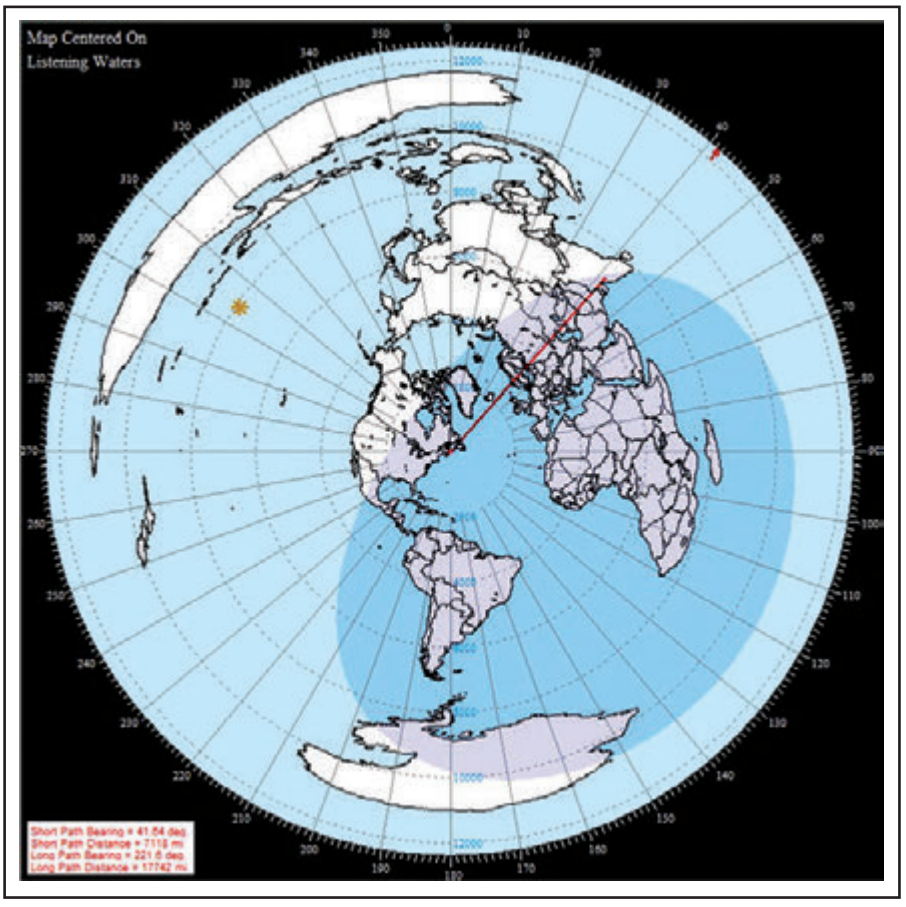
"There will be at least two and as many as 4 or 5 antennas to choose from — and now with Beverage possibilities, maybe even more. One can never have enough splitters and multi-position switches. I'm also going to pack my Quantum Phaser. Bruce has his own custom phasing box and I think Niel just switches on the fly. We'll each — I believe — have access to one feed from each 'community' antenna.

"As for gear power, my battery will be connected to an Anderson PowerPole strip with some empty ports. I also have some spare connectors and a crimper here, which I will ensure I get packed in one of my totes. As for other things, it's never a bad idea to have lots of PL259/BNC adapters and joiners. And, headphones!"

"Believe it or not, Brent, I have forgotten headphones, once!" said Walt. "I'm a BNC fellow. What do the others use? My Alpha Delta switches are PL259, of course, but I have the



Oh, Canada. *Prince Edward Island is part of a vast region in eastern Canada. (Courtesy of Wikimedia Commons)*



Pathfinders. *This AZ mapping of the path to India, a prime DX target, shows a 40-degree bearing from Listening Waters. The Beverage antenna was aimed at 60 degrees toward Europe, midway between India and Africa, which proved to be a good decision.*

adapters for those. My coaxes are all BNC, though. What about lengths? What's the minimum length you'd suggest? Questions, questions!"

"I am a BNC person," remarked Niel. "I pretty much bring everything I can think of that I believe will be useful and that will fit in luggage. I do, indeed, have a Wellbrook active four-way splitter. I think it last saw the light of day last year in Howe Bay."

"Typically Niel and I, and the 'import ringer' DXer set up at a dining room table, and Bruce is adjacent on a table of his own — due to the breadth of his equipment (two laptops, etc.)," said Brent. "So, for our purposes we just need 3-foot lengths for our on-the-table work. We try to port one or two of Bruce's feeds over to our table also, and if there are enough active splitters, we can all share."

"I will have one two-way and one four-way active splitter, both with BNC connections," I replied. "I'm planning on a bi-directional dual Delta aimed toward Japan and Argentina, and a 1,200-foot Beverage aimed toward North Africa. I'll have a couple of 150-foot coax cables, a 75-foot cable, some shorter lengths, twisted pairs, and an assortment of RF matching/isolation transformers for the antenna hook-ups. This week I'm going to build a special transformer for coupling twisted pairs between the two Delta antennas to a coax lead-in."

Aerial Guidance from Above

Antenna planning was facilitated by Google Earth. Satellite imaging allowed for pre-determining antenna layouts and positions. Beverage antenna placement within a 60- to 90-degree bearing would ultimately depend upon agricultural activity in an adjacent field, while there was plenty of room on the 17-acre site for positioning broadband SuperLoop and Delta antennas in any direction.

I was driving my car to the site, so I could bring plenty of wire and coax for antennas. If customs had any questions at the border crossing, I would describe it as *ham radio* gear, something most people understand versus trying to explain a broadcast DXpedition.

"It's always good to bring a back-up receiver," I continued in the email exchange. "There would be nothing worse than traveling a long distance for a DXpedition only to discover that your only receiver crapped out or was damaged during the trip. I will have an Excalibur SDR for the primary receiver, and an RFSpace SDR-IQ for backup. And don't forget to bring an AC power strip so you'll have enough outlets to plug in all your stuff."

The *2013 WRTH*, (World Radio-TV Handbook) and downloads of the latest EMWG (an index of long- and medium-wave stations in Europe <http://www.emwg.info>; PAL (Pacific Asia Log) <http://bit.ly191uqIO>; and MW Offsets (listing of exact frequencies for medium-wave stations) <http://bit.ly/10cLFyz>, were recommended for references. Internet references were to be downloaded to our laptops ahead of time, just in case we didn't have a reliable wireless Internet connection at the DXpedition site.

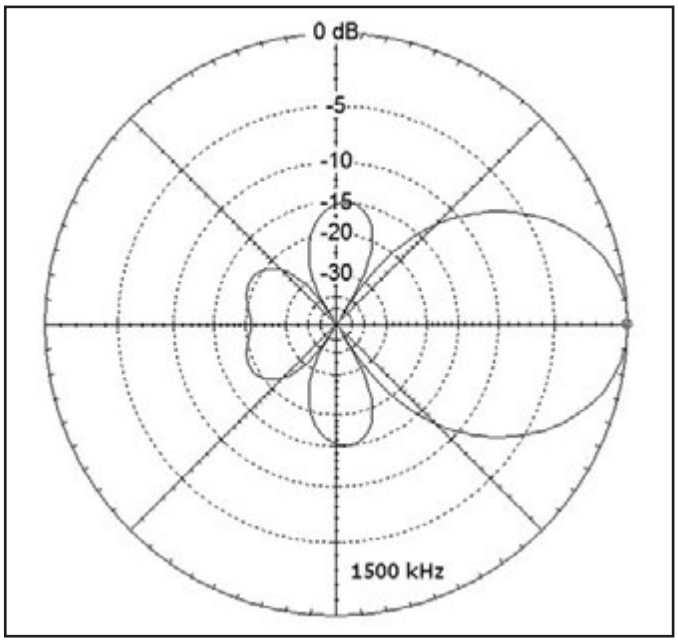
Members of the team also had copies of the NRC AM Radio Log <http://bit.ly/1geTc8M>, and the IRCA Mexican Log <http://www.am-dx.com>. Additionally, we charted sunrise and sunset times along with bearings for various DX target areas. *The DXpedition team was primed and ready to go.*

Savoring the Results

Everyone arrived safely with all their radio gear intact for what was to be an exciting week of AM broadcast DXing. Software-defined-radio receivers ruled the DXpedition, with a Perseus, RFSpace SDR-IQ, and two WiNRADiO Excaliburs capturing all the action, plus an ultralight just for fun.

"Once again, it was a delight to welcome DXers to our little corner of Atlantic Canada," said Brent. "We took full advantage of the 17 acres with a Beverage as well as other antennas. The week was a great time of fellowship, DX, and sharing best practices. While I would have hoped for a more favorable mix of solar-terrestrial indices, the solid captures of India 1071 and Botswana 909 made the whole week worthwhile for me. Grabbing India with my ultralight Sangean DT-400W — inductively coupled to the Beverage wire — was a personal highlight."

"What a treat it was to be totally immersed in fantastic European trans-Atlantic, medium-wave reception, in a lovely location, and very comfortable accommodations," said Walt. "The



A Good Antenna. *EZNEC antenna modeling of a terminated Dual Delta array demonstrates its highly directional capability.*

weather co-operated beautifully, even if the ionosphere didn't always. The thrill of hearing India before 3 p.m. local, and the great camaraderie of seasoned DXers, made the long journey very worthwhile.

"I'm already dreaming of return visits in the years to come. Brent's organizational abilities were much appreciated. Niel's expertise in the MW scene on the East Coast was evident daily, and we all enjoyed his humor. Bruce's technical expertise was very much in evidence, and to watch him rapidly erect Delta loops was something to behold.

"All in all, the total package was a perfect fit for me. Personal highlights in no particular order were: (1) AIR on 1071 daily in the afternoon with the sunshine streaming through the window. (2) LKB/LLE from Norway on 5895 with only 50 watts. (3) The numerous Europirates above 1600 kHz. (4) The magic of having the entire MW band light up starting at 1400 local and continuing throughout the afternoon and late evening, chock block full of European MW stations. Now to just begin to search the TB of Perseus .wav files. Countless hours of memories there, I'm sure!"

"This was another great location," concurred Niel. "Plenty of room for antennas and away from many noise-making devices. Although we did not get any trans-Pacific DX this time, and the Latin Americans were sparse, I'd say we had more than enough from Europe, Africa, and the Middle East to keep us busy from mid-afternoon until it was time to hit the sack. I was especially thrilled to meet Victoria DXer Walt Salmaniw for the first time.

"I had hoped that having him present would be a big help if the trans-Pacific DX began to roll in at sunrise. Still, Walt's presence was handy for identifying the Slavic language broadcasts coming from Europe and also spotting some interesting Europirates above 1600 and shortwave signals, especially the All India Radio outlets."

Assessing the DXpedition's Week

This was my fourth Prince Edward Island DXpedition, after having survived 2009 Priest Pond, 2010 Savage Harbour, and 2012 Howe Bay. Each of these DXpeditions has been a unique experience.

Last year at Howe Bay was most notable for its outstanding tropical reception. *Welcome to Bizarro World* might have been the moniker for this year, as it was the complete opposite of the 2012 experience.

Despite an experimental bi-directional dual Delta array aimed north-south which seemed to be doing the job as it was the only antenna receiving 1220 Brazil, atmospheric conditions weren't cooperating, with otherwise only the usual stuff from Cuba, Puerto Rico, Venezuela, and a couple other regulars received.

The Delta was later terminated to favor south, but still no

Seeing the Sites. *Panmure Lighthouse was among the sights noted as DXpeditioners took time out from their monitoring activities to tour the island.*

Wide spectrum coverage *and* worldwide reception!

ICOM

IC-R6-16

The compact **Icom IC-R6** is big on coverage, tuning 100 kHz-824, 851-866.995 and 896-1309.995 MHz in AM, FM Narrow and FM wide modes. The triple conversion circuit provides amazing sensitivity for the size. Scan 1300 alphanumeric memories at 100 channels per second in 7 scan modes. Frequency steps 5, 6.25, 9, 10,12.5, 15, 20, 25, 30, 50, 100 or 200 kHz. With large backlit LCD. The efficient circuit provides extended operation. Includes wrist strap, belt clip, two AA NiMH cells, AC adapter and SMA antenna. 2.3 x 3.4 x 1.2". List $246.00 *Order #1006* ~~$189.95~~ **$179.99**

www.universal-radio.com

sign of Argentina, Paraguay, and Uruguay. That's OK though, as a trans-Atlantic DX overdose more than made up for it. Check out how we piled on 1071 kHz to hear India. I also enjoyed watching rookie Walt Salmaniw go after those Europirates in the x-band, while stations like "Bluebird" and "Dr. Einstein" provided entertainment between top of the hour RF spectrum captures.

Iran seemed to pop up everywhere, just as noted lately from home base, and the 60-degree Beverage attracted România Actualitati (at 56 degrees) and the U.K. (approximately 60 degrees) like bears to honey. However, there were no bears on this group, as we all collaborated to make this another exceptional DXpedition.

And yes, time does fly when you're having fun. The week flew by so fast that I hardly had enough time to get settled before it was already time to say goodbye.

'Listening Waters' Loggings

Call

The call letters of the station or an indication that it is a Voice of America (VOA) station. Calls of stations that have not previously operated New Not on Air or CP FROM on a given frequency contain a #. W# C# K# (with a number for database integrity) indicate New Not on Air stations with no assigned call letters. A small "n" is a nighttime only operation.

City of license

City of License is shown or in certain cases, cities of authorized station identification. These are shown as they appear in the FCC data base. Even though you may hear multiple cities announced during an ID, that is usually for promotional reasons. My local KCKK-1600 ID's as "Lakewood-Denver"; Lakewood is the City of License, and Denver is the major market that is served.

Station Classes

This discussion focuses on AM radio stations contained in the NRC AM Radio Log, specifically those in the United States and Canada. References are made to stations in other countries in North America as pacts were established between the nations' regulatory agencies as to the enforcement of rules regarding broadcast stations in this region. Since signals in the AM broadcast band travel be-

VHF Propagation

by Neubeck, WB2AMU & West WB6NOA

A comprehensive source-book on VHF propagation by two great authors. Includes: Tropo ducting, Aurora, Meteor Scatter, TEP, Sporadic-E, Combo Modes and more!

Order VHF PROP $15.95

2014 World Radio TV Handbook

Up-to-date info on medium-wave, shortwave, and FM broadcasts and broadcasters. Includes articles of interest to both listeners and DXers, reviews of the latest equipment, maps with SW transmitter sites and much more!

Order WRTH $35.00

The NEW Shortwave Propagation Handbook

by W3ASK, N4XX & K6GKU

This authoritative book on shortwave propagation is your source for easy-to-understand information on sunspot activity, propagation predictions, unusual propagation effects and do-it-yourself forecasting tips.

Order SWP $19.95

W6SAI HF Antenna Handbook

by Bill Orr, W6SAI

W6SAI was known for his easy-to-understand writing style. In keeping with this tradition, this book is a thoroughly readable text for any antenna enthusiast, jam-packed with dozens of inexpensive, practical antenna projects that work!

Order HFANT $19.95

33 Simple Weekend Projects

by Dave Ingram, K4TWJ

Do-it-yourself electronics projects from the most basic to the fairly sophisticated. Practical tips and techniques on creating your own projects.

Order 33PROJ $17.95

Understanding, Building & Using Baluns & Ununs

by Jerry Sevick, W2FMI

The successor to the popular and authoritative Baluns and Ununs. Great deal of new tutorial material, and designs not in previous book, with crystal clear explanations of how and why they work.

8.5 X 11 Paperback $19.95

***New!* CD Version $14.95**

Buy both for only $29.95

Vertical Antenna Handbook

by Paul Lee, N6PL

Learn basic theory and practice of the vertical antenna. Discover easy-to-build construction projects.

Order No. VAH $17.95

The Short Vertical Antenna and Ground Radial

by Sevick, W2FMI

Small but solid guide walks you through the design and installation of inexpensive, yet effective short HF vertical antennas.

BY CORY GB SICKLES, WPC2CS

Freeband: Intervention in a 'Love-Hate' Relationship

Now, stick with me. This setup is a bit long, but you'll soon see the necessity.

In February, we pause the bland, windy chill of winter to decorate with hearts, roses, and other signs of Valentine's Day. This increasingly commercial holiday is a boon for florists and chocolatiers, as well as restaurant owners.

Many a romantic proposal is executed on February 14, either in a public setting or a more private one.

As relationships move further along, though, we may find ourselves in something of a "love-hate" relationship with a *significant other* — a not-too-perfect mix of what we like and what we don't. Some call that "a typical marriage."

Well, this month I'm not thinking about a person — rather, *an activity*. It's one that I don't like, but have also found something about it to admire. It's much like consideration for Attila the Hun: If your village was one of those pillaged, you might find it difficult to admire his management style.

Outside the Lines

While Citizens Band operation beyond the designated channels has been around for some time, advances in technology have made the pursuit easier than ever.

*<wa3uvv@gmail.com>

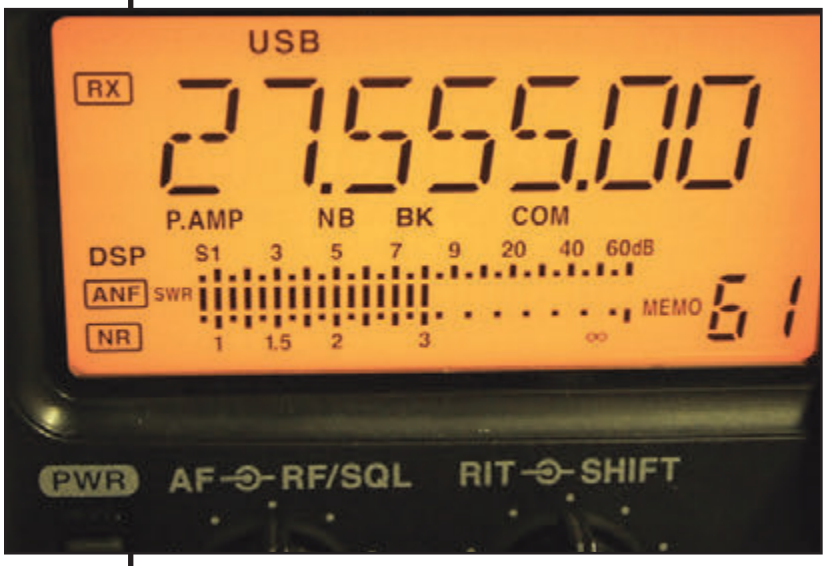

Photo A. *A popular Freeband meeting place — albeit illegal — is 27.555 MHz — not a frequency allocated for Citizen Band operation. (Courtesy of WPC2CS)*

Back in the days of the crystal-mixing-ways of generating 23 channels, some folks worked out ways to access channels 22A, 22B, 23A, and 23B — now known as 24, 25, 26, and 27, respectively, **Table 1**.

Still others, with 5- or 6-channel rigs that used a pair of crystals for each channel, occupied the radio control allocations of 3A, 7A, 11A, 15A, and 19A for communications that was a bit quieter and more secluded — while possibly sending the occasional radio-control (RC) model car to intermittently take off or shudder to a halt.

Still others found ways to incorporate variable frequency oscillator (VFO) technology — also known as a "slider" — to travel pretty much all over the 27-MHz region.

At the same time, others just re-configured amateur radio transceivers of the day to cover this unauthorized spectrum — with 100 to 500 watts of power; much more than allowed.

And With Its Own Name

The term identifying this clandestine slice of spectrum between CB channels is Freeband, occupied by Freebanders who are Freebanding.

All of this activity was — and remains — illegal. Thus, it was with a grimace and frown when I discovered a Freeband watering hole — 27.555 MHz, **Photo A**. This is apparently used by an international group of two-way communications enthusiasts as a calling channel.

That's much like CB Channel 11 was *supposed* to be:

- Make a call for a contact
- When someone answers, move to another channel to talk
- You leave the calling channel free when you move to another channel to chat

With '555, you place a call and let others know you're listening 10 kHz up, 20 kHz down or wherever is presumably clear.

All activity seems to be via SSB, leaving AM behind in these activities.

A Redeeming Value?

While I seriously frown on the whole idea of pirate operations on frequencies allocated to other services, I have to admit that in the case of '555, the channel runs in a relatively polite and professional manner — not unlike amateur radio. (***UNDERSCORE:*** *I'm not condoning this illegal activity. I'm merely marveling at its existence and*

dutifully reporting about it. ***VISUAL:*** *Right now, I'm flailing myself with wet rutabaga leaves just for drawing the Freeband-amateur radio comparison. – WPC2CS.)*

QSL cards are typically exchanged and my limited research shows there even seems to be a loosely run awards program for counties, states, provinces, countries worked, and so on.

As radio amateurs have used the Internet to enhance their interests with sites such as <http://www.QRZ.com>, so have the 11-meter Freebanders with <http://www.QRZ11.com>, **Photo B**. The 27.555-MHz Freeband crowd even has a Facebook page! Several, in fact! *(**VISIT:** For example, the 27.555-Mhz International Frequency DX page at <http://on.fb.me/1dwiJge>,* ***Photo C****. – WPC2CS.)*

A glance through some of the group members' pictures show impressive-looking stations.

27.555 Operators' Gear

What equipment are these Freebanders using? Most seem to have re-tasked amateur radio HF gear and more than a few amplifiers — many of which could produce more power than

Photo B. *The highly-organized Freeband community has a website modeled somewhat on the amateur radio community's QRZ.com. For Freebanders, it's the QRZ11 Forum at <http://www.QRZ11.com>) (Internet screen grab)*

Photo C. *Among several Facebook pages established by, and devoted to Freebanders is the 27.555-Mhz International Frequency DX page at <http://on.fb.me/1dwiJge>. (Internet screen grab)*

even amateurs are allowed. Others have more modest stations, based on "import" radios that allow for multiple blocks of 40 channels, which enable Freeband activities.

Such manufacturers and sellers in the United States skirt the law by marketing them as "10-meter" ham rigs. Trust me, hams aren't buying these, as they are too limited for our purposes and desires. Just cut the magic yellow, blue, or green wire inside (instructions, of course, on the Internet) and you are "good to go" with joining the Freebanders.

FCC Enforcement (?)

While I *do read* about cases where someone is investigated and fined by the Federal Communications Commission — *Huzzah!* — for excessive power and interference, I sadly don't see much, *if any,* in the way of stories about enforcement toward "out of band" activity. Occasionally, a company like ePower Amps will be fined for selling illegal amplifiers (a.k.a. CW transmitters), but I was seeing Facebook ads for its products months ahead of the crackdown. Who knows how many they sold before that? Plus, since the inventory was apparently not confiscated, who knows how they eventually may have "disposed" of the inventory? *(**IN DEPTH:** Read an FCC Citation and Order for "Illegal Marketing of Unauthorized Radio Frequency Devices" against ePower Amps at <http://bit.ly/1i9lxlp>. – WPC2CS.)*

I guess it's a matter of priorities. There's more illegal activity to go around than the Commission can address. Broadcasters and other business owners are easier targets — high profile, with serious bank accounts. If the harmonics of some poorly-made amplifier interfere with aviation or public service, then it becomes a higher priority. If not, it seems to be ignored.

Factor in all of the other countries and agencies involved and I imagine the task of enforcement and "putting the toothpaste back in the tube" becomes incredibly daunting. No doubt, that's what the Freebanders are counting on, too.

Simply Put ...

For me, *CB is CB* and *ham radio is ham radio.* I have all sorts of transceivers that could be modified and used for such clandestine activity and it would technically be easy to join the crowd on 27.555 (and 26.985) MHz.

But for more than 45 years, I've chosen to keep the two separate and enjoy each for what it is. *So have most of us.*

While I am duly impressed at the scale and sophistication that this activity has risen to, I have to ask why these folks don't just channel their energies — and money — into amateur radio?

An Invitation to Freebanders

If you are a Freebander and would like to "clean up your act" to experience a broader world of *legal* communications, I think the amateur radio community would welcome you. If the thrill of working outside of the law is the most important thing, then please stay where you are.

27-MHz Channels and Frequencies

Table 1.

The Need for a Smoothed Solar Index — Accurate Propagation Predictions, Part II

BY CARL LUETZELSCHWAB, K9LA

In the first of this two-part series, I discussed why we need a smoothed solar index — to best characterize a solar cycle. This month's column addresses a second reason why we need a smoothed solar index — to achieve the best accuracy with propagation predictions. *(**NOTE:** See Part I on the CQ Plus Internet landing page at <http://www.CQPlusPracticalPropagation.blogspot.com>. – KI6SN)*

To analyze this accuracy issue, we'll focus on the *CQ World Wide SSB* contest, which took place at the end of October last year. By the way, the higher bands were excellent.

We'll use ionosonde data for the one-month period centered on October 26 and 27 — the weekend of the contest. We'll use the Boulder (Colorado) ionosonde from October 12 through November 10 at 1900 UTC as it had tabular data for both October and November 2013. **Figure 1** presents this data, along with the 10.7-cm solar flux for the same period.

There is a lot of information in **Figure 1**.

- The solid orange curve is the daily MUF (maximum useable frequency) over the Boulder ionosonde assuming it's the midpoint of a 3,000-km (1,864 miles) F_2 region hop. Note that it varied from a low of 29 MHz on October 12 to a high of 37 MHz on November 8. There were many ups and downs throughout the one-month period.
- The dotted orange curve is a linear trend line for the MUF and indicates that the MUF had an overall increasing trend during the period.
- The solid blue curve is the daily 10.7-cm solar flux. It started at a value of 128, dipped to a low of 125 on October 14 and 15, peaked at a high of 167 on October 27, decreased to around 140, and then increased at the end of the period.
- The dotted blue curve is a linear trend line for the 10.7-cm solar flux, and indicates that the 10.7-cm solar flux also had an overall increasing trend during the period.

We can draw two important conclusions from this data. The first is that the MUF and solar flux do not appear to be very well correlated on a daily basis. This is best seen from October 21 to October 30, when the solar flux reached its highest values but the MUF was up and down significantly. In fact, the highest solar flux on October 27 resulted in one of the lowest MUFs during the entire period.

*K9LA@arrl.net

A better way to see the correlation between the daily solar flux and the daily MUF is through a scatter plot. Each daily solar flux value and daily MUF value is plotted and then a trend line is added to determine the correlation factor R-squared.

- An R-squared value of 1.00 means perfect correlation — all the data points would be on the trend line.
- An R-squared of 0.00 means no correlation — all the data points would be scattered widely about the trend line.

Figure 2 is the scatter plot for the data in **Figure 1**.

As expected, the extremely low value of R-squared (highlighted in red) tells us the correlation between the daily solar flux and the daily MUF is poor. For example, for a solar flux of 128, the MUF could have been 29 MHz or 34.5 MHz. In other words, a daily solar flux value does not map to a unique daily MUF.

The second conclusion is due to the fact that the solar flux and MUF trend lines are parallel, which tells us that solar flux and MUF follow a linear relationship. But this relationship is on a long-term basis — not on a daily basis. As can be seen, the higher the solar flux, the higher the MUF. This should not be new news. The fact that this does not apply on a daily basis may be new to you.

Why doesn't the daily MUF follow the daily solar flux? The reason is that although solar radiation certainly instigates the ionization process, ultimately the ionization at any given location is also

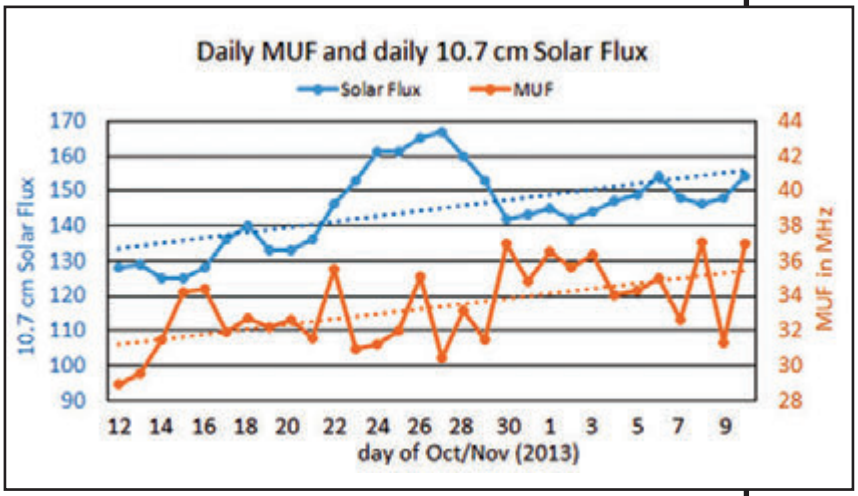

Figure 1. *Solar Flux and Boulder Data*

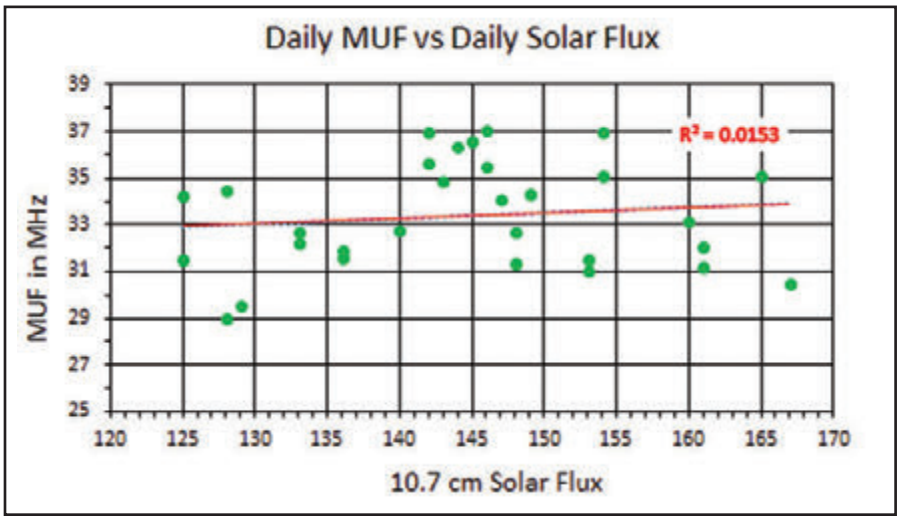

Figure 2. *Scatter Plot*

dependent on geomagnetic field activity and events in the lower atmosphere coupling up to the ionosphere.

*(**IN DEPTH:** See my August 2004 WorldRadio column titled "The Day-to-Day Variability of the Ionosphere" for more details on this issue. Visit <http://www.k9la.us>. Look under the General link. Included in the piece are scatter plots showing the poor correlation between the daily 10.7-cm solar flux and the daily MUF over the Millstone Hill (Massachusetts) ionosonde. – K9LA.)*

If the daily correlation is poor, how was a model of the ionosphere developed for propagation prediction purposes? When scientists discovered that the correlation was poor between daily values, they moved on to a longer-term correlation — which turned out to be between a smoothed solar index and monthly median parameters of the ionosphere. What this means is our model of the ionosphere is a monthly median model. This inherently says our propagation predictions are probabilities over a month's time frame.

To better understand the improved correlation with a smoothed solar index, let's look at some scatter plots that compare the daily correlation to the smoothed correlation. We'll do this for the Boulder ionosonde (but at a different date than the data in **Figure 1**) and the Canberra (Australia) ionosonde. **Figure 3** shows this data.

At both ionosondes, the daily solar flux versus daily MUF results in poor correlation. But the correlation between the smoothed solar flux and the monthly median MUF is extremely high.

What this means is a smoothed solar flux value maps much better to a unique monthly median MUF. This is what is needed for accurate propagation predictions, and is the second reason why we need a smoothed solar index.

Next month's column will review smoothed solar indices, monthly median ionospheric parameters and the interpretation of propagation predictions.

73, Carl, K9LA

NW7US February HF-VHF Outlook

On an Electromagnetic Wing and a Snowy Winter Evening's Prayer

BY SHANNON HUNIWELL, WPC2HUN

Metaphorically, AM skywave signals are a bit like little joys in life. They're capriciously fleeting, though sometimes manage to have the power for appearing in the most unpredictable places. If they're long enough to be recognized by name, such a definitive callsign identified greeting almost always brings its recipient cheer.

My father has a favorite winter DX story that exemplifies this radio reception/life comparison. Dad made me a bit suspicious by prefacing the following tale with an uncharacteristic admission that he can't recall who told it to him, exactly where it occurred, or to what station the saga relates. After tightly closing his eyes and rubbing his temples, he was able to guesstimate that the story's listener was navigating some treacherously ice-covered road in northern Michigan and inadvertently snagged a 250 watter "approximately in West Virginia." Even so, he is willing to swear that "the episode took place just before midnight on a snowy winter night ... probably in the early 1970s."

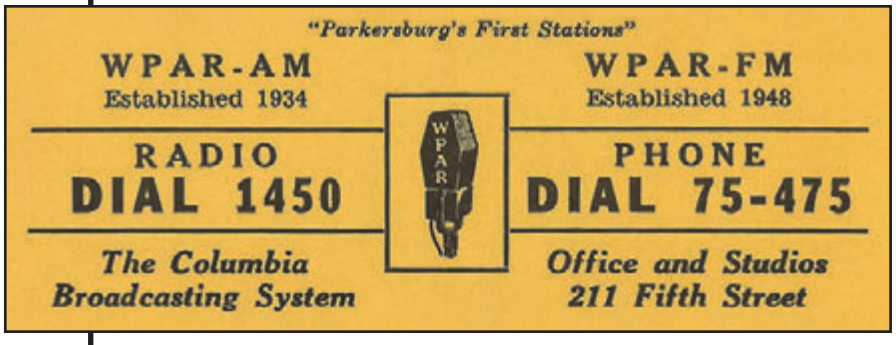
Dad, Are You Sort Of Reasonably Sure That This One Is At Least *Semi-Authentic?*

According to Huniwell legend, the driver of a 1963 Studebaker Champ pickup truck — how my father remembers that automotive detail above broadcast facts, always made me wonder, but anyway — this fellow had promised his elderly mother that he would come home for a visit sometime during the holidays. The old homestead was located near the top of the Upper Michigan Peninsula, a bit of a hike from the busy little St. Louis-area tool and die manufacturing shop where he served as manager. Crunch work had required him to oversee several priority projects that left him and a couple of loyal employees occupied all but part of Thanksgiving and Christmas day. Happily, their tenacity enabled the company to meet its customers' robust orders, and the firm's delighted owner rewarded his staff with a week of vacation starting on December 31st of whatever year Dad couldn't envision. The Studebaker driver — we'll call him, Joe — packed a few clothes, boxed a sample of the parts that had kept him so tied up, tossed the stuff on the front seat of the truck, and headed north to surprise his mom. Conveniently, the Studebaker was allegedly equipped with a "pretty darn good AM radio," an electronic feature that the fellow used as a constant roadway companion throughout the journey's many miles and hours.

My poetic license will have to kick-in here, as I conjecture that when the traveler encountered the icy highway somewhere around Routes 131 and 66 in Kalkaska County, Michigan. Local radio reception way up there and near the witching hour was probably none too great. Arguably, Joe was likely dialing big city skip or maybe a thread of 50-kilowatt ground wave from Chicago or Detroit.

Whatever was tickling the tuner, though, left suddenly when the Studebaker hit a patch of black ice that sent it spinning across the opposite lane. This rotation rapidly propelled Joe's luggage from the seat to the dashboard. A corner of the box in which the sample parts were packaged catapulted against the radio's tuning buttons before dumping its contents onto the passenger floor. Its crescendo coincided with the lengthy blast of an 18-wheeler's air horn from an oncoming tanker that had seemingly come out of the snowy nowhere. Joe braced himself for the impact and flash, but it never came. Instead, he found himself shaken-up and tightly gripping the wheel of his Studebaker, a trusty truck that was still very much intact, though, about a dozen feet off of the road and pointing south. Its engine had stalled, but when Joe regained his composure, he became conscious of a strong signal pouring through the radio.

e-mail: <Melodyfm@yahoo.com>



It's any reader's guess which West Virginia AM was fortuitously snagged by our first story's main character, Joe, while hundreds of miles away from "The Mountain State." Because my father, Sid Huniwell, was reticent about recalling the subject station's identity, I always suspected it might actually have been 50,000-watt country music giant WWVA 1170. "Absolutely not that flamethrower!" Dad would protest. "Besides," he claimed, "Joe's catch was definitely some tiny West Virginia outlet on a local channel." As such a broadcast facility arguably occupied some Class IV, "graveyard," or local channel, it might have been Parkersburg, WPAR 1450 — noted on this advertising card. Then again, 1240 WDNE, Elkins; WMON 1340, Montgomery, WV; or maybe Bluefield's WKOY 1240 could have been among the mighty little 250-watt signals that skipped to the tale's upper Michigan reception point.

In a decided drawl, the bucolic announcer was wishing whomever "might be listening" a happy New Year. The DJ hoped that the occasion would provide folks in his typically tiny audience opportunity for "visiting and cheer." And then the radio host introspectively mused about having lost his wife during the previous winter and that his daughter lived in California and they hadn't seen each other since the funeral. "But don't mind me," he said, "I should be glad that the Good Lord saw fit to let me stay at the microphone for another New Year's Day." With that, the announcer noted it was officially midnight, invited listeners back at 6 a.m., when he would be filling in for the regular morning DJ, and then read the sign-off copy.

Joe was incredibly surprised to hear that the station hailed from a little town in West Virginia and used only a quarter kilowatt after sunset. These facts prompted him to wonder what the announcer there might think if he were to know that Joe had received the fellow's heartfelt New Year's Eve message in a shallow ditch aside a slippery Michigan highway. Joe switched on his truck's dome light, fished a pencil from the glove compartment, and jotted the station's call letters and city of license on the cardboard box he'd retrieved from the floor. He hadn't even finished the fourth letter when the scratchy, wowing LP track of Auld Lang Syne, on a warped Guy Lombardo record that the old announcer had selected as his swan song, evaporated into the ether.

When one thinks of vintage pickups, the long-defunct Studebaker marque seldom comes to mind. While it is doubtful that the formally-dressed admirers in this 1960 ad realistically represent eager truck buyers, the pictured vehicle did attract enough attention from those wanting to show Ford and Chevy owners that some folks didn't care about following the commonplace crowd. Whether Joe's edition of the Champ was equipped with six or eight cylinders is unknown, though his did sport an optional AM push-button radio.

Mail Call!

This story's epilogue simply includes that Joe offered a thankful prayer to God for having spared him, for the Studebaker getting right back on the road, and then making it to his mother's house a couple of hours later, as well a note he penned to *The DJ On Duty New Year's Eve*, in care of the station's calls and locale.

Nearly a year later, a reply arrived. At first, Joe wondered why he was getting correspondence from a radio station in West Virginia, but the message inside quickly jogged his memory and warmed his heart. Again, I'm using poetic license here, although Sid Huniwell, my radio nut father who first told me this saga, claims it's "spot on and nearly word-for-word" what was written on Joe's correspondence:

Greetings from West Virginia,

First off, I want to officially confirm that you did, indeed, hear our signal all the way up in Michigan last December 31st! That's quite a haul for 250 watts part way across this great country. Our contract engineer thinks it is the farthest reception report we ever got and figures that conditions were just right for the skywave skip, especially since there are probably 30 stations between here and there on our local or Class IV frequency. So, it's a feat for us, too! Any DX'er (or long-distance radio listening buff) would be proud to post verification of such a catch in his radio shack (or on his pick-up truck dashboard, as the case may be)!

What I most want to tell you, however, is that your note made our old Bill Shumaker smile. He was the fellow you

My radio buff father emailed me this eBay seller's image of an early 1960s Studebaker radio. He wanted me to be sure to note the tiny CONELRAD Civil Defense triangle symbols at 640 and 1240 kilocycles. I was most interested, however, in the AM set's five plastic push buttons like the one that got rammed with flying cargo and ended up tuning some very good DX.

heard last New Year's Eve. Word of your long-distance reception even made a mention of a few lines in our local weekly newspaper. I know Bill sure appreciated your kind note about how he cheered you up after your near crash. Old Bill showed your letter to everybody at the station and then some. He wasn't much for writing so had asked me to send you a verification and thanks. I admit he asked me three or four times and always I just said "Don't worry, I'll get to it." Bill passed on this past October and I hate to say I'm just getting around to sending this letter. Anyway, I don't think it was any coincidence that you heard him that night. I guess you could say that it really put a nice cap on his radio career in this town and re-started Bill's once famous smile. What the Good Lord can do with a humble 250 watts when he wants to reach somebody's heart!

Sincerely,
Jim Pierce, Program Director

A Smudged Postmark And No Return Address

If you've ever misplaced a letter, only to find it years later, you'll understand my joyful squeal when flipping open a long dormant *Broadcasting Yearbook* and happening upon something just right for this month's second small AM radio station epoch. Inside the plain business-size envelope clumsily stamped with what sort of looks like the "Z" of an Arizona postmark, was a single sheet article from the September 1997 *Guideposts* magazine. The piece, titled "*My Computer Prayer*" by Lois Lonnquist of Helena, Montana, had little to do with keyboards, monitors, and hard drives. Rather, it focused on a previously defunct standard broadcast facility that the author and her husband had just returned to the airwaves surrounding Great Falls, Montana.

Reportedly, during the winter of 1987, Mrs. Lonnquist's husband, Del, was growing restless after selling their two Midwestern radio outlets and attempting to be retired. Like many authentic local radio guys, he quickly missed what he knew best — hometown station ownership/operation. That led to perusing media brokers' prospectuses and eyeing that Class IV, single-kilowatt Great Falls station that had gone off the air and was down for the FCC count of *12 months dark and get deleted*. Mrs. Lonnquist wasn't convinced that this AM should figure into their plans, but, as she recalls, "We had 25 years of experience in radio. So, Del and I prayed for guidance, put our home up for sale, and made our move." Once in Great Falls, though, she wasn't particularly impressed with their new investment, writing, "We found a weathered one-story building surrounded by knee-deep prairie grass, and a chilly wind whistled through the silent station's 240-foot tower greatly in need of paint." As any radio man might imagine, husband Del didn't see things so gloomily. "We're going to love it here," he exclaimed to his skeptical spouse. Del Lonnquist then used some of that enthusiasm and a hammer to "pry-off some boards from a porch window [through which they] climbed for their first glimpse of the sad AM's dusty microphones and turntables." It took the couple nearly a month to rig-up the gear for re-introduction into the rest of their revitalization project carrying the call letters, KXGF.

Mailed to a hardware store on July 2, 1954, this business envelope from 560 KMON survives as one of the few pieces of early Eisenhower-era Great Falls radio memorabilia floating around on the Web. It is likely to have contained an invoice seeking payment for advertising on the 5-kilowatt outlet then owned by the Montana Farmer-Stockman *agricultural publication. The original KMON construction permit was issued in 1946 to Sun River Broadcasting Company for a 5,000-watt AM on 970 kilocycles, and construction of the station began early the next year. It quickly signed with ABC for network affiliation.*
Jan Lowry's research showed that before KMON 970 was ever completed, however, its "permit was sold by Sun River Broadcasting to the Montana Farmer Broadcasting Corporation. That firm then turned in its own permit for partially-built KMFR 560 in Great Falls. The KMON permit was modified by the FCC from 970 to the more favorable 560 kilocycle dial position ... with three, 440-foot-tall, guyed towers situated five miles south of the city and overlooking the Missouri River." Logically, a reason for this amalgamation of uncompleted CPs was to eliminate some potentially stiff competition in a relatively small media market.

The Lonnquist's — including a son, Roger, who served as engineer — decided that a primarily satellite-delivered big band/nostalgia music focus and local information would play well in Great Falls, so instituted that brand of mature programming. "Listeners loved the format," Lois noted, "but many advertisers were wary and waited for us to prove ourselves."

This lack of anticipated ad revenue got exacerbated by "payments from the

buyers of their Midwestern stations that were slow in coming." The couple essentially lived at KXGF 24/7 in order to run it parsimoniously. Several months into this seemingly unending marathon, she sat at her modest station's business office computer and typed a letter to God. The missive concluded with the urgent question, "How long can we go on?" Mostly, she wondered why they had felt directed to put KXGF back together. These queries got followed by a strong depression onto the question mark key that accented Lois' quandary with a monitor filled with: ??????????

The Fan Letter Made In Heaven

Lois Lonnquist's mood wasn't much brighter the next morning as she negotiated a stack of mail predominantly comprised of bills and too few checks from advertisers. The last envelope in that pile, however, contained a simple note from an elderly man who wanted the folks at KXGF to know that he and his wife were instant fans of the reborn station.

"We've been so happy to hear its old familiar tunes." The next paragraph told of his wife's recent illness and how KXGF kept them both in pleasant company, especially when his wife was awake in the wee hours battling pain. "Your music soothed her," he thanked the "dear friends at KXGF. And then early this morning, your announcer played *I'll Be Seeing You*, our favorite song. My wife looked at me and smiled," the listener recounted before closing with, "A short time later, she passed away."

Suddenly, Lois Lonnquist was filled with renewed appreciation for her radio station's ability to reach people and make a positive difference in their lives, even if only for a little while. She felt that the reminder had been an answer to a prayer. By the end of the year, a group approached the Lonnquist's with a respectable offer for KXGF, and the family accepted it. The *Guideposts* piece ends with Lois indicating that she and her husband later found a couple more stations to buy. Out of all of those radio projects, though, she smiles, "KXGF is our favorite."

A Hobson's Choice Of Hertzian Waves

For at least a couple of decades, even the most fickle Great Falls area radio listener would have to admit that the process of picking his or her best-loved local station was a no brainer. That's because — with the fleeting early '20s exception of KDYS, a 50-watt experiment of the *Great Falls Tribune* newspaper — from 1922 until after World War II, radio fans in the Montana city of about 50,000 had but one hometown audio voice, KFBB (now KEIN 1310 5-kilowatts day/1-kilowatt night). Great Falls broadcast buffs anticipated a treat, however, when learning of the extreme aural expansion planned for their community circa 1947-48.

During that brief period, the *Broadcasting Yearbook* not only noted KFBB, but four full time AM construction permits, each with all of the serious promise of call letters and imminent on-air target dates: KMFR (560 kilocycles, 5 kilowatts), KMON (790 kilocycles, 5 kilowatts), KGFM (1150 kilocycles, 5 kilowatts), and KXLK (1400 kilocycles, 250 watts).

As things shook down and the prospective station owners reconsidered their likely return on investment, two of the 5-kilowatt permit holders merged — resulting in KMFR on 560 kilohertz — and the 790 CP never actually materializing. Nor did KGFM go beyond paper. At just a quarter kilowatt and a 150-foot rooftop tower, the smallest of the post-war lot, KXLK, beat these others to be KFBB's first real competitor. Officially, KXLK was FCC-autho-

WORLDWIDE LISTENING GUIDE

John Figliozzi's brand new, expanded 6th edition *Worldwide Listening Guide* explains radio listening in all of today's formats – "live," on-demand, WiFi, podcast, terrestrial, satellite, internet, digital and, of course, AM, FM and SW. Includes a comprehensive program guide to what can be heard how, when and where. Link to WWLG website keeps you up-to-date on program schedule changes. Spiral bound to open in a flat, easy-to-use format. Order today for Holiday delivery.

WWLG $24.95

USING YOUR METER

Teach yourself the correct use of your multitester. Book explains fundamental concepts of electricity including conventional and electron current and series and parallel circuits. It teaches how analog and digital meters work and tells you what the voltage, current and, resistance measurements mean. Then it provides fully-illustrated, step-by-step instruction on using your meter in practical applications in the home, workshop, automotive and other settings. An excellent learning tool and reference for the hobbyist and ham.

Had this linen postcard of the Park Hotel been published about 10 years after its supposed late 1930s rendering, the picture would have included signage denoting tenant KXLK, predecessor to KXGF, the modest AM survivor in our story. No doubt, too, there's be pictorial evidence of a bit of the Great Falls station's tower pointing north from the five story venue's roof.

rized in late June 1946 as KSTR. But by its March 1947 debut, the little AM was called KXLK to reflect the "XL" family of sister Montana radio outlets, KXLF Butte, KXLJ Helena, KXLL Missoula, KXLO Lewiston, and KXLQ Bozeman.

The Park Hotel at the corner of Great Fall's Central Avenue and Park Drive served as KXLK's first home. Jan Lowry's research details that the establishment not only housed the station's studio and business offices, but also contained its transmitter (in the basement) and antenna on the roof. Not much out of the ordinary shows up on KXLK's history until a 1958 sale and callsign change in 1960 to KARR. Nearly coinciding with this new identity were an early 1961 daytime power increase to a kilowatt, as well as a new Great Falls studio/transmitter venue at 1900 Third Street, N.W. Jan cites an "upbeat Middle-of-the-Road music format on KARR from 5:30 a.m. until 2 a.m. daily" circa 1971, plus a litany of ownership transfers in 1973, 1977, 1982, 1986 (when soon thereafter, it apparently went dark), 1987, 1989, 1995, and 2006. Jan also notes a 1989 studio shift to 1300 Central Avenue, West. Along the way, KARR became KYOT (in summer 1984), and then KXGF during 1987. In addition to the longtime M-O-R offering, 1400 kilohertz in Great Falls once featured a religious format, "Hit Album Rock Music," C&W tunes, big bands/standards, hot adult contemporary, and sports talk programming KXGF uses its 680 watts (mandated in a 2000 tower move to a new Fox Road site just south of Great Falls) in order to broadcast today.

That Small Station In The Little *Guideposts* Magazine

Though not mentioned specifically in Jan's FCC-mined data, it appears that the Lonnquist's contribution to the resilient 1400 kilohertz Montana survivor was their 1987 re-casting it as KXGF after believing the station to have worth beyond its modest power. While they didn't keep the station very long, the radio family succeeded in resurrecting KXGF's signal so that it could bring a bit of joy to whomever needed the friendship available within the reach of its fleeting radio waves.

And so ends another broadcast day from the Radio Drama studios.

unwired

BY RICHARD FISHER, KPC6PC

The Weirder Side of Wireless, and Beyond

Au Naturel: 'No Antenna? Noisy Location? No Problem!

OK, imagine you're in the most remote, radio-quiet spot on the planet and want to hear what the rest of us city slickers can't. Put on your *"I'm Gloating"* hat and link to <http://www.ab9il.net/vlf>, "Natural Radio VLF Listening Via the Internet" where you can bask in some of the best RF that's ever bombarded Earth.

*(**HOUSEHOLD HINT:** Why invest in a "white noise" generator when you've got this? Crank it up and go zzzzzzzzzzzzzzzzzz ... – KPC6PC.)*

FCC: 'We Can Hear You Now'

What price ambience? It could ring up to more than $100K for Perfect Cuts Salon in San Antonio, Texas.

It seems the Federal Communications Commission does not like the cut of Ronald Bethany's lights, which it alleges have been putting out a signal on 705 MHz. Did we mention that's the frequency used for AT&T's 4G services? Did we mention its cell site *is right next door?*

AT&T tipped off the FCC which not-so-subtly warned it might take a little off the top of Perfect Cuts.

"If, after receipt of this citation Mr. Bethany again violates Section 15.5(b) of the Rules by engaging in conduct of the type described herein, the Commission may impose monetary forfeitures not to exceed $16,000 for each such violation or each day of a continuing violation, and up to $112,500 for any single act or failure to act."

There hasn't been a battle involving hair this fierce since the Beatles invasion of 1964.

*(**READ:** The FCC citation at <http://bit.ly/1cxRlbP>. – KPC6PC.)*

Drawing a Blanc: 'You Bend It, We Mend It'

Bugs Bunny, Daffy Duck, Porky Pig, Tweety Bird, Sylvester the Cat, Yosemite Sam, Foghorn Leghorn, Marvin the Martian, Pepé Le Pew, Speedy Gonzales, Wile E. Coyote, the Tasmanian Devil, and lots of other characters from Looney Tunes and Merrie Melodies popped up on Los Angeles-area Citizens Band when Mel Blanc was on the air.

But that wasn't the only radio "show" in which he starred. For a year beginning in 1946, "The Mel Blanc Show" featured "the man of 1,000 voices" as the hapless owner of "Mel's Fix-It Shop."

Listen to 42 knee-slapping episodes free online at <http://bit.ly/16YKwgW>.

***SILICON VALLEY ADJACENT.** It doesn't take long on a walking tour of San Francisco to realize that while you might not be in Silicon Valley, you're awfully close. The **Kilowatt** is a sports bar on 16th Street, **The Fusion Hotel** towers above Ellis Street, and get an Earth-shaped pizza at **The Orbit Room Café** on Market Street. Radio, physics, and space travel all in one marquee-friendly stroll. Keep your head up and your cellphone camera ready! (Courtesy of KPC6PC)*

MFJ Big Stick™

18 Foot *Portable* Telescoping Antenna

Only 28 inches collapsed . . . Covers 40-6 Meters -- No gaps!

MFJ-2286
$99.95

The MFJ BigStick™ antenna is for the on-the-go Ham who is hungry for the next great QSO anywhere or anytime!

Full Size Performance

For top portable performance, carry a *Big Stick* for the loudest, strongest on-the-go signal on the band!

MFJ's extra long 17 foot stainless-steel telescoping whip gives you *full-size antenna* for full size performance 20 to 6 Meters but collapses to just 28 inches.

An ultra low loss, high-Q adjustable *air-wound* loading coil gives you highly efficient operation 30 and 40 Meters.

This extra long radiator and ultra low loss loading coil is a winning combination that stands head and shoulders above shorter backpack antennas.

True Backpack Portability

Antenna is over 18 feet long fully extended, but disassembles and collapses to 28 inches in seconds. Fits into most backpacks or suitcases! And at just over 2 pounds you'll hardly know you are packing it!

True General Coverage

Tapped loading coil covers 7.0-55.0 MHz without gaps. Great for Ham Bands and outstanding for image-free shortwave broadcast!

Everything you need

Everything is included for instant operation. Pipe/Mast mount quickly and easily mounts to any pipe or mast up to 1/2 inch. SO-239 for coax. 3/8-24 antenna connector.

Counterpoise kit included: Ensures low SWR, high efficiency.

Rugged Construction

All aluminum, stainless steel construction ensures years of excellent performance. *One Killowatt rated* components guarantee electrical safety.

40-2 Meters Apartment Antenna

MFJ-1622
$99.95

MFJ-1622 universal mount/clamp lets you attach it to window frames, balconies and railings. Works great indoors mounted to table/bookshelf. It's not a 5-element yagi, but you'll work your share of exciting DX! Highly efficient air wound *"bug catcher"* coil, telescoping 4½ foot radiator. Collapses to 2½ feet for easy storage and carrying. Includes coax, choke balun, counterpoise wire, safety rope. Operating frequency adjusted by moving "wander lead" on coil and adjusting the counterpoise for best SWR. ***Optional DX-Getter,*** MFJ-1977, $44.95. Stainless-steel 12-ft whip, 26 inches collapsed.

MFJ *BigEAR™*

8-Band Portable Dipole

34 feet Radiators, 7-55 MHz

For hams on-the-go!

Operate anywhere, anytime with a strong QSO grabbing signal!

34-Feet stainless steel radiator gives you *full-size dipole* performance on 20-6 Meters and highly efficient ultra *low loss* loaded dipole performance on 30/40 Meters. Collapses to 27 inches to fit into any suitcase or backpack. No ground or counterpoise needed.

True general coverage -- tunes up with low SWR on any frequency 7-55 MHz. Handles QRP to full killowatt PEP.

Ultra low loss high-Q *air-wound* loading coil. Built-in Guanella current balun kills feedline radiation, pattern distortion, RF shifts, RFI and noise pickup.

Distinctive V-shaped elements are set 45 degrees from the horizon to keep element tips high in the air. This maximizes radiation, minimizes ground loss and prevents hazardous contact.

MFJ's heavy-duty *NoTool™* mast lock lets you easily and quickly mount on any tripod or mast up to 7/8 inches. SO-239 for coax. With fewer parts to assemble, set-up and tune-up is much faster!

18 foot Telescopic Fiberglass Mast with Tripod

MFJ-1919EX, $139.95.

***Put your antennas anywhere and get them up high with this super-strong* 18 foot telescoping fiberglass mast and heavy-duty steel MFJ-1919 tripod.**

QuickClamps™ easily collapses mast to 5 feet. Mast has thick 1/8 inch wall, .75 inch diameter top, 1.5 inch bottom. 15 lbs.

All tripods are black heavy-duty steel with braced triangle base, non-skid feet and mast lock.

MFJ-1918EX, $89.95. MFJ-1918 *tripod with super strong 9.5 foot telescoping fiberglass mast.* Collapses to 3.8 feet. *QuickClamps™*. Mast has thick 1/8" wall, ¾ inch top, 1 inch bottom. Weighs 6.5 lbs.

Tripods Only

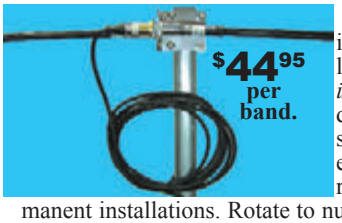
MFJ-1919, $89.95, *Large tripod*. Supports 100 lb. antenna. Built-in 1.4 inch diameter mast extends 7.8 feet. Collapses to 4.5Hx.5D feet. Triangle base spreads to 4.8 feet on a side. Weighs 9.75 lbs.

MFJ-1918, $49.95, *Smaller tripod*. Supports 66 lbs. 1 inch diameter mast extends 6 foot. Collapses to 3.2Hx.3D feet. Triangle base spreads to 2.75 feet. Weighs 6.75 lbs.

17 foot *Stainless Steel* Telescoping Whip

MFJ-1979, $59.95. Super-strong, super long *17 foot stainless steel* telescoping whip. 27 in. collapsed. 10 sections. 3/8-24 threaded base. **MFJ-1977, $44.95**/12ft;**MFJ-1796, $39.95**/10ft **MFJ-1974, $34.95**/8ft;**MFJ-1972,** $14.95/4½ft

Single-band Rotatable *mini*-Dipoles



Use these inexpensive, lightweight, *isolated* mini-dipoles when space is limited for temporary or permanent installations. Rotate to null QRM/noise and to focus your signal. Coax choke balun, mast not included. For 40/30/20/17/15/12/10/6 Meters. Order **MFJ-22XX** (insert band in "XX") **$44.95**. 75/60 Meters, $49.95 each. Total length 14 feet. For mounting masts up to 1.25" OD.

The radio... YAESU

HF/50 MHz 100 W Transceiver

FT DX 3000

New Crystal Roofing Filters provide ultimate weak signal receiver performance in crowded, strong signal environments

The amazing Crystal Roofing Filter performance

The Down conversion 9 MHz 1st IF frequency receiver construction, can realize narrow 300 Hz (optional), 600 Hz and 3 kHz bandwidth roofing filters.

Outstanding receiver performance, the heritage of the FTDX5000!

The high dynamic range IP3 performance that was realized and proven in the FTDX5000.

IF DSP provides effective and optimized QRM rejection

Independent Frequency display

The newly developed LCD has a wider viewing angle and higher contrast.

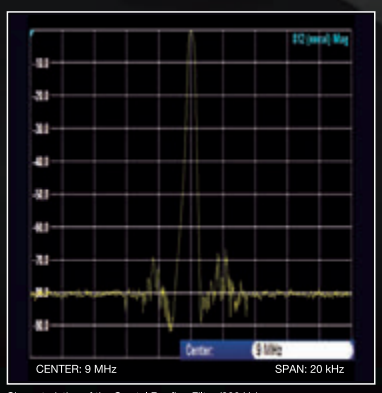
4.3-inch Large and wide color LCD display with high resolution

High Speed Spectrum Scope built-in

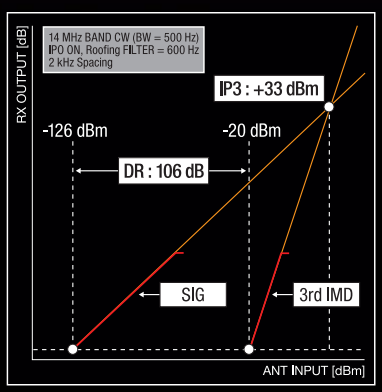
AF SCOPE display and RTTY/PSK encoder/decoder

Other features

The specialized Receiver amplifier for 50 MHz is built in / Three antenna connectors are provided / The "ANT-3" terminal may be assigned to "RX-only" / Signal output for an external receiver and the 9 MHz IF output are furnished / High speed Automatic antenna tuner built in / Optional μ-tune unit available / USB interface equipped



Characteristics of the Crystal Roofing Filter (300 Hz)



3rd Order Dynamic Range / IP3 (2kHz Spaceing)
